2. An atmospheric steam-condensing apparatus, consisting of two or more series of condenser-sections, the condensing-surfaces of each of said sections being corrugated and said corrugation serving to maintain each section in an operative condition and being of proper strength, the vertical ends of said sections being united to split heads, a base to which the lower horizontal edges of each section are connected, a crown to which the upper horizontal edges of said walls of each section is connected, the said crown having tapering sides which direct the inflowing water around the surfaces of each section, means for bracing and connecting the walls of each section throughout, and a manifold steam-header to which each condenser-section has its own independent connection, substantially as specified.

3. In an atmospheric steam-condensing apparatus, the combination with a manifold steam-header having a series of valves thereon, of one or more series of condenser-sections connected to said steam-header, each of said condenser-sections consisting of two corrugated walls which present two exterior and continuous corrugated surfaces, the said walls being connected to front and rear upright heads, the front head of each section connecting with the steam-header by suitable couplings, a crown or water-distributing head to which the upper horizontal edges of said walls are connected, a base to which the lower horizontal edges of said walls are connected, and roller-supports upon which each section is independently supported, substantially as specified.

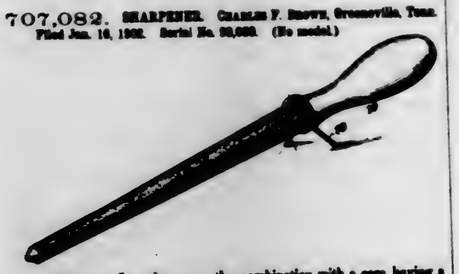
4. In an atmospheric steam-condensing apparatus, the combination of a series of vertical walls corrugated throughout, and each two of such walls constituting a condenser-section, split upright front and rear heads to which the vertical edges of said walls are united, a steam-header connected to the front one of said upright split headers, a horizontal crown or water-distributing header to which the upper horizontal edges of said walls are connected, a base to which the lower horizontal edges of said walls are connected, the said base providing a chamber for the water of condensation, and a baffle-plate having a series of angles, the said baffle-plate being located throughout the length of said base and forming a seal

between the water of condensation and the steam, openings in said baffle-plate through which the water of condensation passes below said baffle-plate, substantially as specified.

5. In an atmospheric steam-condensing apparatus, a series of condenser-sections, each of which consists of two walls corrugated throughout to present continuous corrugated surfaces, interior braces and supports projecting from the interior surfaces of said walls and serving to prevent any undue bursting or collapsing pressures of said walls, upright heads connecting the vertical ends of said walls, said heads each consisting of two parts which are united, a crown or water-distributing head connecting the upper horizontal edges of said walls and providing a distributing-surface from which the water is directed to the outer surfaces of said walls, a base having an interior water-chamber, a baffle-plate having a series of angles with openings therein through which the water of condensation is discharged below said baffle-plate, the said baffle-plate forming a seal between the steam and water of condensation, an outlet from said chamber, and roller-supports upon which each condenser-section is mounted, substantially as specified.

6. In an atmospheric steam-condensing apparatus, the combination with a steam-header consisting of a series of sections, each of which is provided with a valve, of a series of condenser-sections each of which consists of two walls corrugated throughout, a front and rear head to which the vertical ends of said walls are united, the front head being connected to one of the sections of the steam-header and affording means for the passage of steam to the condenser, a crown to which the upper horizontal edges of said walls are connected, said crown having a tapering water-surface from which the water is directed to the outer side of the condensing-walls, a base to which the lower horizontal ends of said walls are connected, said base having a water-chamber therein, a baffle-plate located within said chamber and extending throughout the length thereof, the rearward end of said baffle-plate terminating on a higher plane than the forward end thereof, means for supporting the baffle-plate within the chamber, and a valve-controlled outlet at the rear end of said chamber, substantially as specified.

707,082. SHARPENER. CHARLES F. BROWN, Greenville, Texas. Filed Jan. 16, 1902. Serial No. 89,669. (No model.)



Claim.—1. In a sharpener, the combination with a core having a seat, of a cover removably fitted upon the core and having an outer abrasive face, and holding means engaging the cover and forcing a portion thereof into the seat of the core to hold the cover upon said core.

2. In a sharpener, the combination with a cylindrical core having an annular groove, of a cover removably fitted upon a core and having an outer abrasive face, and a clamping-ring surrounding the cover and forcing a portion of the same into the groove.

3. In a sharpener, the combination with a body having a tapering core at one end, and a handle at the other, said core being provided at its larger end with an annular groove or socket, of a tapering cover fitted upon the core and having an outer abrasive face, and an expansible and contractible clamping-ring fitted over the cover and forcing a portion thereof into the socket of the core.

4. In a sharpener, the combination with a body having a handle at one end and an abrasive surface at the other, of a support for the body comprising an expansible ring that surrounds the same, said ring being formed of a single wire the terminals of which are disposed in spaced projecting relation and constitute supporting-feet for the sharpener.

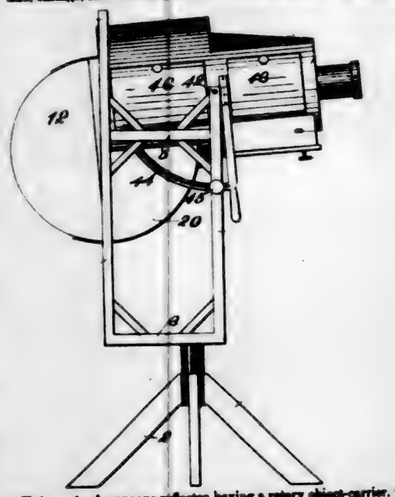
707,083. CAR-SEAL. JOHN H. BRENNER, Morrison Park, Minn. Filed Apr. 3, 1902. Serial No. 101,169. (No model.)

Claim.—1. A car-seal, comprising a socket of thin sheet metal having the edges of its wall and bottom on one side folded to interlock with a space between the fold so formed and the bottom of the socket, and a shackle having hooked ends adapted to interlock, and a lip or flange provided on one of said ends and adapted to enter the space between said folds and the bottom of the socket and be clamped therein by the crimping of said folds.

2. A car-seal, comprising a rectangular socket having a wall 5 at one end, the opposite end being open and a flange 7 provided on a side wall and having an inwardly-turned edge 8 to interlock with a correspondingly-turned edge 9 of the bottom 4, a space being provided between said flange 7 and said bottom, a shackle having hooked ends adapted to interlock, and a lip or flange provided on said shackle near one end and adapted to enter said space and be clamped therein by the crimping or pinching of said folds.

3. A car-seal, comprising a socket of comparatively thin sheet metal having its bottom and a side wall interlocked by turning the edge of the bottom over a flange on the wall and then folding the turned edge and flange toward the wall, a recess being provided between said flange and bottom, and a shackle having hooked ends adapted to interlock and a laterally-extending lip or flange to enter said recess and be secured therein.

707,084. IMAGE-PROJECTING APPARATUS. CHARLES W. CARHART, Chicago, Ill. Filed May 2, 1902. Serial No. 105,585. (No model.)



Claim.—1. An opaque reflector having a rotary object-carrier, provided with a plurality of radially-disposed object-holders, pivotally mounted at the periphery of the object-carrier and meeting at the axis thereof, movable toward and from the axis, and means for securing the object-holders in adjustment, substantially as described.

2. In an opaque reflector, a rotary object-carrier, comprising a pair of disks arranged parallel with one another intersecting plates forming radially-disposed supports, object-holders pivotally connected to the outer edges of the said supports, and adjusting means for securing swinging adjustment of the object-holders with respect to the plates, substantially as described.

3. An opaque reflector comprising a hollow body, consisting of a rear cylindric casing, a lens-tube extending forwardly from the casing, an object-carrier rotatably supported by the said casing, and including a plurality of radially-disposed supports, each provided with an object-holder, the said holders being pivotally secured to their supports, while the carrier is so mounted that the holders can be brought into projecting position in succession by the rotation of the carrier, lamp-boxes on opposite sides of the hollow body, lamps arranged in said boxes, and transparent walls between the lamps and the object-carrier, substantially as described.

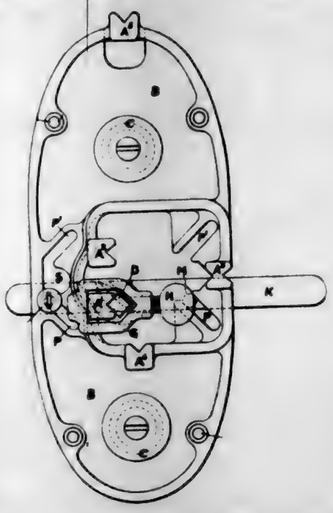
4. In an image-projector, the combination with a rotary object-carrier, of a plurality of object-holders, pivoted at the periphery of the object-carrier, and movable toward and from the axis of rotation thereof, and means whereby the object-holders may be adjusted toward and from the axis of rotation, the said means including slotted stripe 17, one for each object-holder, and extending at right angles to the object-holder, and fastening-screws passing through the slots, substantially as described.

5. In apparatus of the class described, the combination with a plurality of image-projecting means, of a pivotally-mounted source of light adapted to be operatively associated with one or the other of the said image-projecting means by its rotation, the said image-projecting means serving to cast images in opposite directions with respect to each other, and a pivotal mounting for the aforesaid mechanism, whereby the apparatus may be adjusted to throw images upon the same screen at different times from both image-projecting means, substantially as described.

6. In apparatus of the class described, the combination with a plurality of image-projecting means serving to project images in opposite directions with respect to each other, of a source of light adjustably mounted, whereby it may be operatively associated with one or the other of the said image-projecting means, and a rotatable mounting for the above apparatus, whereby the apparatus may be adjusted to throw images upon the same screen at different times from both image-projecting means, substantially as described.

7. In apparatus of the class described, the combination with a plurality of image-projecting means serving to project images in opposite directions with respect to each other, of a source of light common to the plurality of image-projecting means, and a rotatable mounting for the above apparatus, whereby the apparatus may be adjusted to throw images upon the same screen at different times from both image-projecting means, substantially as described.

707,085. RECESSING OR GROOVING PLANE. FRED CLAYTON, Pudsey, England. Filed Apr. 1, 1902. Serial No. 100,915. (No model.)



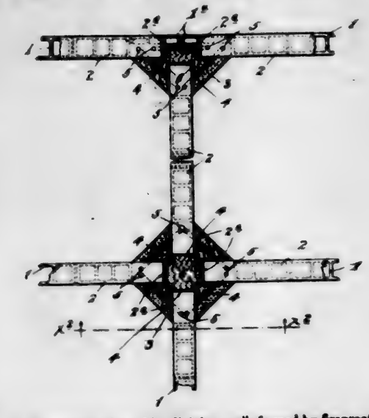
Claim.—1. The combination, with a plane-body provided with a series of separate tool-posts arranged in different planes, of a clamp for securing tools to the said posts, substantially as set forth.

2. The combination, with a plane-body provided with separate tool-posts arranged in different planes and having also oblique slots, of an adjustable slide provided with fastening devices which engage with the said slots, and a clamp for securing tools to the said posts, substantially as set forth.

3. The combination, with a plane-body provided with separate tool-posts arranged in different planes and having also two pairs of oblique slots for right and left hand side tools provided with fastening devices which engage with the said slots, and a clamp for securing the tools to the said posts, substantially as set forth.

707,086. FIREPROOF BUILDING. FRED W. COOLEY, Minneapolis, Minn., assignor of two-thirds to George T. Mountain, Minneapolis, Minn. Filed Mar. 26, 1902. Serial No. 99,532. (No model.)

Claim.—1. The combination with adjoining walls formed by fireproof blocks and interposed metal bars or beams, of a solid corner-column formed of concrete, which metal bars have projecting ends embedded in said corner-column, and a binder embedded in said column and anchored to the embedded ends of said bars, substantially as described.



2. The combination with adjoining walls formed by fireproof blocks and interposed metal bars or beams, of a solid corner-column formed of cement, which metal bars have projecting ends embedded in said corner-column, and the tie-links 4 embedded in the said column and provided with ends 5 passed through perforations in the embedded ends of said bars, substantially as described.

3. The combination with adjoining walls formed by fireproof blocks and interposed metal bars or beams, of a solid corner-column formed by a solid body of cement, which metal bars have projecting ends bent or extended vertically and embedded in the said concrete corner-column, substantially as described.

4. The combination with walls formed of fireproof blocks and interposed metal bars or beams, of a corner-column formed by a solid body of cement, which metal bars have projecting ends bent or extended vertically and embedded in said concrete column, and a metal binder rigidly tying together the embedded ends of said bars, substantially as described.

5. The combination with adjoining walls formed by fireproof blocks and interposed metal bars or beams, of corner-columns formed of cement, which metal bars have projecting ends embedded in said columns, a metal binder rigidly connecting the embedded ends of said bars, and the angle-iron columns placed at the corners of the adjoining walls and embedded in said column, substantially as described.

707,087. DRIP-PAN FOR PAINTING METAL FURNITURE. HERMAN R. CROSS, Jersey City, N. J. Filed May 17, 1902. Serial No. 107,716. (No model.)

Claim.—1. A drip-pan for painting articles of furniture or parts thereof, said pan comprising two parts one of which is adapted to rest in a horizontal position and the other of which is normally held in a raised or inclined position, a shaft mounted transversely of said pan and in the end of the horizontal portion thereof adjacent to the other portion thereof, and a perforated plate connected with said shaft and adapted to rest on the bottom of the horizontal portion thereof, substantially as shown and described.

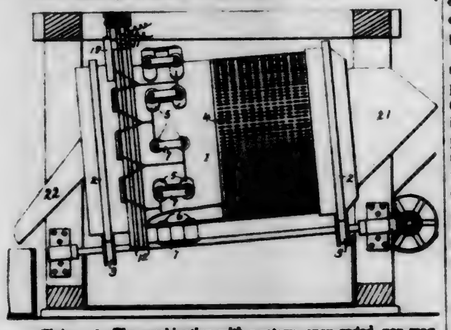
2. A drip-pan for painting articles of furniture or parts thereof, said pan comprising two parts one of which is adapted to rest in a horizontal position and the other of which is normally held in a raised or inclined position, a shaft mounted transversely of said pan and in the end of the horizontal portion thereof adjacent to the other portion thereof, and a perforated plate connected with said shaft and adapted to rest on the bottom of the horizontal portion thereof, and said plate being provided near said shaft with a bracket or support, substantially as shown and described.

3. A drip-pan for painting articles of furniture or parts thereof, said pan comprising two parts one of which is adapted to rest in a horizontal position and the other of which is normally held in a raised or inclined position a shaft mounted transversely of said pan and in the end of the

horizontal portion thereof adjacent to the other portion thereof, and a perforated plate connected with said shaft and adapted to rest on the bottom of the horizontal portion thereof, and said plate being provided near said shaft with a bracket or support, and said pan being provided adjacent to said shaft with a transverse screen, substantially as shown and described.

4. A drip-pan for use in painting cabins of furniture or parts thereof, said pan being oblong in form and composed of two parts, one of which rests in a horizontal position and the other of which is held in a raised or inclined position the transverse screen mounted in said pan at the junction of the two parts, a shaft transversely mounted in said pan adjacent to said screen and provided with a perforated plate which is secured thereto and adapted to normally rest on the bottom of the horizontal part of the pan, said plate being provided adjacent to said shaft with a transverse bracket and at the opposite end thereof with a recess, and said shaft being provided with a crank, substantially as shown and described.

707,088. MAGNETIC SEPARATOR. ALVIN DUNN, Milwaukee, Wis. Filed Apr. 8, 1901. Serial No. 54,771. (No model.)



Claim.—1. The combination with a rotary, open-ended, non-magnetic cylinder; a series of electromagnets mounted thereon; magnet-cores extended through the cylinder and provided with rounded heads on the interior surface thereof; annular conducting-rings located on the cylinder; and brushes for connecting the same with a source of electrical energy, said magnets being electrically connected in series with rings; a resistant bar for each magnet also electrically connected with the rings, and adapted to serve as a shunt for its corresponding magnet when in contact with a terminal beyond such magnet; and a segmental shoe located in the path of the bar and adapted to force the bar downwardly into contact with the terminal when passing the shoe, said bar being normally out of contact with the terminal.

2. The combination with a diagonally-disposed, rotary, non-magnetic cylinder; of a cylindrical screen forming a continuation thereof, at its upper end; an annular series of electromagnets externally disposed around its lower end; conducting-rings connected with a source of electrical energy, and electrically connected with the magnets; and circuit-controlling mechanism adapted to energize and demagnetize the magnets consecutively, each of said magnets being provided with a core extending through the cylinder, and headed on the interior surface, said core and head being integral, and the head being rounded or cuneiform in form, whereby it not only serves to hold the magnet in position, but also concentrates the magnetic force over a small surface exposed to the material passing through the cylinder.

3. The combination with a rotary, non-magnetic cylinder provided with an annular row of magnets, and conducting-rings adapted to convey an electrical current through the magnets; of a series of resistant bars, each member of which is connected with the circuit on one side of one of the magnets; a terminal located in the circuit, on the other side of each magnet, and normally out of contact with its corresponding bar; and a segmental guide-shoe arranged in the path of the bars, and adapted to force them into contact with their terminals; said bars being arched and arranged for regular sliding contact with the guide-shoe.

707,089. CORE-PAD. IRA BENJAMIN, Fort Smith, Ark. Filed May 23, 1901. Serial No. 61,612. (No model.)

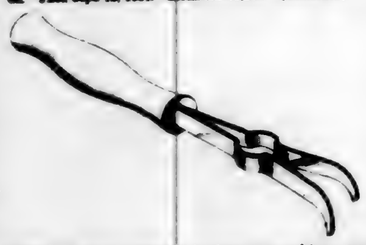
Claim.—A core-shield comprising a head having a recess formed on its inner face and walls gradually reduced in thickness from the bottom toward the top thereof, the outer face of said walls being smooth and unbroken, said recess having the walls thereof converging toward the top of said head, a thin covering extending over the top of said recess, and means for holding said head in adjusted position.

707,090. LACING-HOOK. WILLARD A. DURHAM, Weymouth, Mass. Filed Mar. 5, 1902. Serial No. 96,767. (No model.)

Claim.—1. The one-piece lacing-hook above described, comprising an attaching member, a shank and two tongues integral therewith, and projecting laterally from the same side of said shank, one B, of said tongues forming the head of said hook, and the other tongue C being stamped out of said tongue B, and both tongues projecting laterally from the same side of said shank, the tongue B lying over the tongue C and forming a protection therefor, and the tongue C being bent down somewhat to divide the space between the tongue B and the attaching member into two chambers, one over the other and both over the attaching member, each chamber being of sufficient size to receive a lacing-cord, as and for the purposes described.

2. A blank for a lacing-hook comprising a portion to form an attaching member, a portion extending laterally to form a shank, and a portion beyond said shank to form a lacing-receiving member, said attaching member, said shank portion and said lacing-receiving portion being located in the same straight line, said lacing-receiving portion being provided with two slits extending in a straight line from its extreme edge toward said attaching member parallel with the length of the blank whereby said lacing-receiving member may consist of two tongues, one of said tongues being forked, the other tongue being formed from the portion of the blank between said forks, the two tongues being capable of being bent, the one under the other, to form two parallel coextensive chambers, the one over the other and both directly over said attaching member, as described.

707,091. SUGAR-CANE STRIPPER. THOMAS A. DEVTON, Egypt. Filed Sept. 12, 1901. Serial No. 75,260. (No model.)



Claim.—1. A cane-stripping implement comprising a metal strip folded upon itself to form a shank or tang and having the folded portions outwardly diverged and terminating in hooked grabbing-points, and having portions intermediate of their ends oppositely curved, and having corresponding edges of the curved portions sharpened, substantially as described.

2. A cane-stripper consisting of a handle having an opening in one end, and a strip folded upon itself to form a shank or tang fitted in the opening of the handle, and having the folded portions outwardly diverged and terminating in hooked grabbing-points, and having portions intermediate of their ends oppositely curved, and having corresponding edges of the curved portions sharpened, substantially as specified.

707,092. DRAFT ATTACHMENT. CHARLES H. FALK, Hinsley, Kans. Filed Mar. 11, 1902. Serial No. 97,726. (No model.)

Claim.—1. In a draft attachment, the combination, with a main pole, and steering mechanism carried by it; of an auxiliary draft-pole having its rear end pivotally connected to the said main pole, substantially as set forth.

2. In a draft attachment, the combination, with a main pole, and steering mechanism carried by it; of a guide secured to the front end portion of the said main pole, and an auxiliary draft-pole having its rear end pivotally connected to the said main pole and its front end portion slidable in the said guide, substantially as set forth.

3. In a draft attachment, the combination, with a main pole, and steering mechanism carried by it; of a guide secured to the front end portion of the said main pole, an auxiliary draft-pole having its rear end pivotally connected to the said main pole and its front end portion slidable in the said guide, and a locking device for securing the said auxiliary draft-pole in the said guide in different positions, substantially as set forth.

4. In a draft attachment, the combination, with a main pole, and steering mechanism carried by it; of an auxiliary draft-pole having its rear end pivotally connected to the said main pole and arranged underneath it, and a doubletree pivoted to the front end portion of the said auxiliary draft-pole and arranged between it and the main pole, substantially as set forth.

707,093. METHOD OF BUILDING SUBAQUEOUS FOUNDATIONS. JAMES T. FORD, Cartagena, Colombia. Filed Apr. 10, 1902. Serial No. 102,260. (No model.)

Claim.—1. A method of constructing subaqueous foundations, consisting in first sinking a shaft, then tunneling beneath the water-bed, and then reinforcing said tunnel from within to convert it into a superstructure-supporting foundation.

2. A method of building subaqueous foundations consisting in first sinking a shaft beyond the water's edge and down to bed-rock, then excavating along bed-rock, walling said excavation, constructing on top of said foundation thus formed, and walling said second excavation.

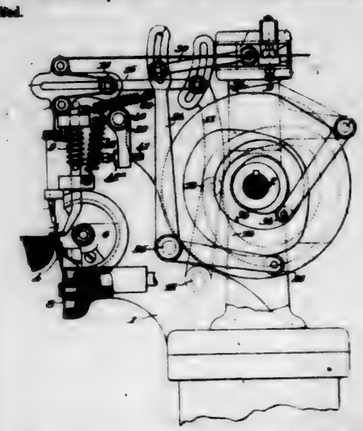
3. A method of constructing subaqueous foundations consisting in first sinking shafts on opposite sides of the water's edge, down to bed-rock, then tunnelling along bed-rock from shaft to shaft walling or lining the tunnel as it is dug, then building another tunnel on top of the first and so on up to the desired height.

4. A method of constructing subaqueous foundations consisting in first sinking shafts on opposite sides of the water a safe distance from the water's edge and down to bed-rock, then tunnelling along bed-rock from shaft to shaft connecting the tunnel-walls to the desired thickness, and then building tunnel on tunnel until the desired height is reached.

5. A method of constructing subaqueous foundations consisting in sinking one or more shafts to the desired depth, then tunnelling from said shaft or shafts beneath the water-bed to the desired length for the foundation, then walling, lining or filling said tunnel or tunnels, and then erecting the dam or other structure on said tunnel or tunnels.

707,094. LOCK-STITCH SHOE-SEWING MACHINE. ALFRED B. FOSTER, Boston, Mass., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Nov. 4, 1901. Serial No. 81,805. (No model.)

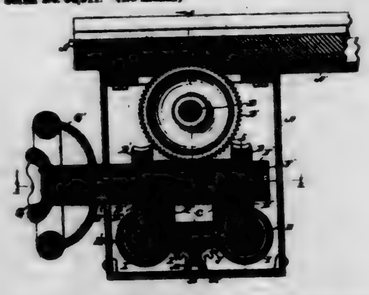
Claim.—1. A lock-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism including a take-up, an intermittently-acting thread-clamp which engages the thread between the supply and the take-up and holds the supply end against the pull of the take-up, and means for moving the thread-clamp while closed in the direction of the lead of the thread to pull off thread from the supply, substantially as described.



2. A lock-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism including a take-up, an intermittently-acting thread-clamp which engages the thread between the supply and the take-up and holds the supply end against the pull of the take-up, and means for moving the thread-clamp while closed in the direction of the lead of the thread to pull off thread from the supply, said clamp remaining closed while the stitch is being set by the take-up, substantially as described.

3. A lock-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism including a take-up, a presser-foot, an intermittently-acting thread-clamp which engages the thread between the supply and the take-up, and means for moving the thread-clamp while closed in the direction of the lead of the thread a distance governed by the position of the presser-foot to pull off an amount of thread from the supply proportional to the thickness of the work, substantially as described.

707,095. FEED MECHANISM FOR MILLING-MACHINES. WILLIAM R. FOX and MATTHEW LEES, Grand Rapids, Mich., assignors to the Fox Machine Company, Grand Rapids, Mich. Filed Dec. 6, 1901. Serial No. 84,911. (No model.)



Claim.—1. In a feed mechanism for a milling-machine, the combination of a casing A; a shaft B supported in suitable bearings therein; a suitable feed-rack; a toothed wheel B' on said shaft B adapted to mesh with said rack; a frame C having guides K fitting within suitable vertical guideways within the casing; a shaft E having a worm E' thereon supported in the said framework adapted to mesh with said toothed wheel B'; flanges E'' central in form on said shaft E; worm-gears D, D', supported on the shaft E; a rod F through the center of said shaft screw-threaded at F' and provided with a head F'' to fit against the worm D; a hand-wheel G' on said shaft E adapted to fit against the worm-gear D'; a hand-wheel G within the hand-wheel G', whereby, by manipulating the hand-wheels G, G', either worm-gear D or D' can be readily fixed on the shaft E or both of them released; a tumbling-rod; a shaft I' car-

nected with said tumbling-rod by a suitable telescopic joint; a driving-gear J on said shaft I'; shafts I, I, arranged to each side of said shaft I'; gears J', J', on said shafts I, I, meshing with said gear J; worms H, H', on said shafts I, I, meshing with the worm-gears D, D', one of which worms is right-handed and the other left-handed; a bar M in the bottom of said casing having inclined planes M', M', secured thereto fitting against inclined surfaces in the bottom of the casing; a lever L provided with a suitable handle L' connected to the said bar M and provided with a notch in its upper end; a latch N, N', for engaging said notch; a pin P supported in a suitable guide resting on the end N' of the latch; a coiled spring *e* for forcing the same normally upward; a suitable stop on said carriage adapted to engage the said pin P and automatically disconnect the feed mechanism when the carriage has reached the end of its travel, all coacting substantially as described for the purpose specified.

2. In a feed mechanism for a milling-machine, the combination of the casing A; a shaft B supported in suitable bearings therein; a suitable feed-rack; a toothed wheel B' on said shaft B adapted to mesh with said rack; a frame C having guides K fitting within suitable vertical guideways within the casing; a shaft E having a worm E' thereon, supported in the said framework adapted to mesh with said toothed wheel B'; flanges E'' conical in form on said shaft E; worm-gears D, D', supported on the shaft E; a rod F through the center of said shaft screw-threaded at F' and provided with a head F''' to fit against the worm D; a hand-wheel G' on said shaft E adapted to fit against the worm-gear D'; a hand-wheel G within the hand-wheel G' whereby, by manipulating the hand-wheels G, G', either worm-gear D, or D' can be readily fixed on the shaft E, or both of them released; a tumbling-rod; a shaft I' connected with said tumbling-rod by a suitable telescopic joint; a driving-gear J on said shaft I'; shafts I, I adapted to mesh with the gear J; worms H, H' on said shafts I, I, meshing with the worm-gears D, D', one of which worms is right-handed and the other left-handed; a bar M in the bottom of said casing having inclined planes M', M', secured thereto, fitting against inclined surfaces in the bottom of the casing; means for automatically controlling said bar to disconnect the feed mechanism when the carriage has reached the end of its travel, all coacting substantially as described for the purpose specified.

3. In a feed mechanism for a milling-machine, the combination of the casing A; a shaft B supported in suitable bearings therein; a suitable feed-rack; a toothed wheel B' on said shaft B adapted to mesh with said feed-rack; a frame C having guides K fitting within suitable vertical guideways within the casing; a shaft E with a worm E' thereon supported in the said framework and adapted to mesh with said toothed wheel, B'; worm-gears D, D', supported on the shaft E; means for rigidly securing either worm-gear D or D' to the said shaft E or of releasing both of them; a tumbling-rod; a shaft I' connected with said tumbling-rod by a suitable telescopic joint; a driving-gear J on said shaft J'; shafts I, I, arranged to each side of said shaft I'; gears J', J' on said shafts I, I, adapted to mesh with said gear J; worms H, H', on said shafts I, I, meshing with the worm-gears D, D', one of which worms is right-handed and the other left-handed; a bar M in the bottom of said casing having inclined planes M', M', secured thereto, fitting against inclined surfaces in the bottom of the casing; means for automatically controlling said bar to disconnect the feed mechanism when the carriage has reached the end of its travel, all coacting substantially as described for the purpose specified.

4. In a feed mechanism for a milling-machine or lathe, the combination of a suitable casing; a suitable feed-rack on the carriage of said machine; a frame adjustable up and down within said casing; a worm-gear adapted to engage with said rack; a shaft; a worm thereon for actuating the said gear, the said shaft being carried in the movable frame; worm-gears on said shaft resting outside of suitable flanges; a screw through the center of said shaft with a head at its outer end for embracing one of said worm-gears and clamping it against the flange and a collar on the other end of the shaft to be forced against the flange by the said screw to clamp the worm-gear at the end, whereby either of the said worm-gears can be securely clamped in position while the opposite is left free, or both can be released; worms transverse to each of said gears, one of which is right-handed and the other left-handed; suitable gears J', J', on the shafts with the said transverse worms and a driving-wheel between them and meshing therewith, whereby the direction of the actuation of the carriage is changed by clamping one or the other of the worm-gears on the shaft bearing the main driving-worm, or the carriage is freed by releasing both of the said worm-gears, coacting for the purpose specified.

5. In a feed mechanism for a milling-machine or lathe, the combination of a suitable casing; a suitable feed-rack on the carriage of the machine; a frame adjustable up and down within said casing; a worm-gear adapted to engage with said rack; a shaft; a worm thereon for actuating the said gear, the said shaft being carried in the movable frame; worm-gears on said shaft resting outside of suitable flanges; a screw through the center of said shaft with a head at its outer end for embracing one of said worm-gears and clamping it against the flange by the said screw to clamp the worm-gear at that end, whereby either of the said worm-gears can be securely clamped in position while the opposite is left free, or both can be released; worms transverse to each of said gears, one of which is right-handed and the other left-handed; suitable gears J', J', on the shafts with the said transverse worms and a driving-wheel between them and meshing therewith, whereby the direction of the actuation of the carriage is changed by clamping one or the other of the worm-gears on the shaft bearing the main driving-worm, or the carriage is freed by releasing both of the said worm-gears, coacting for the purpose specified.

6. In a feed mechanism for a milling-machine or lathe, the combination of a main worm-gear; a hollow shaft with a worm thereon and meshing with said gear; worm-gears carried by said shaft, one of which is right-handed and the other left-handed; flanges on said shaft between said gears; a screw-threaded rod engaging a thread in the interior of said shaft with connections for clamping either one or the other of said gears against the flanges on said shaft or releasing both of the same, and a right-hand worm and a left-hand worm meshing with said worm-gears, with connections for driving the said worms, whereby the direction of the feed can be changed by clamping one of said worm-wheels or the other on the shaft carrying the main worm, as specified.

7. In a feed mechanism, the combination of a hollow shaft; right-hand and left-hand worm-gears thereon; a clamping means consisting of a screw-threaded rod extending through said hollow shaft and having connections at each end for clamping either of said gears securely to the shaft or releasing both of them; right-hand and left-hand worms engaging with the said gears whereby the direction of the rotation of the shaft is changed by clamping the one or the other of said worm-gears thereto, as specified.

8. In a feed mechanism, the combination of the shaft E with flanges E'', E'' thereon; gears to fit against said flanges; a screw-bolt through said shaft with a head at one end to engage the hub of the gear at that end to clamp the same and a collar on the opposite end for clamping the gear at that point; hand-wheels on the said bolt and on the shaft for turning the same and changing their relative position, whereby either of the said gears may be clamped or both freed; connections for driving the said gears in opposite directions whereby the direction of the shaft can be changed by clamping the one or the other, and whereby the shaft can be disconnected by releasing both of the said gears, coacting for the purpose specified.

9. In a feed mechanism, the combination of a casing; a driving-gear; a frame adapted to be adjusted in said casing; gearing carried by said frame for actuating the carriage of a milling or similar machine; a bar with inclined planes thereon adapted to raise or lower said frame-work to throw said gearing into or out of engagement with the driving-gears, for the purpose specified.

10. In a milling-machine, the combination of a casing A; a driving-wheel within said casing; a movable frame within said casing; suitable gearings carried by said casing; a bar with inclined planes for adjusting the said casing to throw said gearings into or out of engagement with the driving-wheel; a lever connected to said bar; a latch to engage said lever with a spring for holding the same normally into engagement; a trip-pin adapted to act on said latch and a stop on the carriage adapted to engage said trip-pin, whereby the carriage will automatically release the lever and throw the mechanism out of gear when it has reached the end of its travel, coacting for the purpose specified.

707,096. COTTON-GIN. JAMES T. FULLER, Calvert, Tex. Filed Aug. 24, 1901. Serial No. 73,117. (No model.)

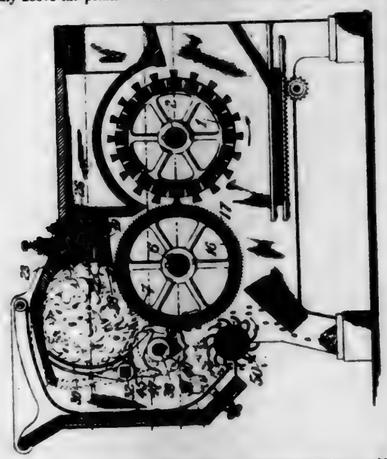
Claim.—1. In a cotton-gin, a ginning-cylinder provided with ginning-points arranged in circumferential rows, in combination with stripping-fingers provided with blade-like end portions which project circumferentially over the surface of the cylinder between the rows of ginning-points below the ends thereof.

2. In a cotton-gin, a ginning-cylinder carrying circumferential rows of ginning-points, in combination with spaced stripping-fingers having blade-like end portions which project over the surface of the cylinder between the rows of ginning-points and extend upwardly above the points to form a slotted wall for the inner breast.

3. A stripping-finger for cotton-gins having a blade-like end portion shaped to extend circumferentially over the surface of the ginning-cylinder, and a body portion arranged at an angle to the end portion.

4. A stripping-finger for cotton-gins having a pointed end portion shaped to extend circumferentially over the surface of the ginning-cylinder, and a body portion arranged at an angle to the end portion.

5. In a cotton-gin, the combination of a ginning-cylinder provided with circumferential rows of independent pin-like ginning-points, and stripping-fingers having a blade-like end portion shaped to extend circumferentially over the surface of the cylinder and a body portion extending upwardly above the points to form a slotted wall for the inner breast.



6. In a cotton-gin, the combination of a ginning-cylinder provided with circumferential rows of independent pin-like ginning-points in combination with stripping-fingers provided with blade-like end portions which project circumferentially over the surface of the cylinder between the rows of ginning-points and below their apices, substantially as shown and described.

7. A stripping-finger for cotton-gins having an end portion shaped to extend circumferentially over the surface of the ginning-cylinder and carrying at its extremity a downwardly-projecting lip.

8. A stripping-finger having a pointed end portion shaped to extend circumferentially over the surface of the ginning-cylinder and carrying at its point a downwardly-projecting lip.

9. In a cotton-gin, the combination of a ginning-cylinder provided with circumferential grooves, a row of ginning points between the grooves, stripping-fingers having an end portion which projects circumferentially over the surface of the cylinder between the ginning-points, and lips carried by the stripping-fingers and extending into said grooves.

10. In a cotton-gin, the combination of a ginning-cylinder provided with ginning-points arranged in circumferential rows, a surface of relatively yielding material between the ginning-points and stripping-fingers having end portions which project over such surface.

11. In a cotton-gin, the combination of a ginning-cylinder provided with ginning-points arranged in circumferential rows, a surface of relatively yielding material between the ginning-points and stripping-fingers having end portions which project over said surface and body portions arranged at an angle to the end portions and spaced to form a slotted wall for the inner breast.

12. In a cotton-gin, the combination of a ginning-cylinder provided with ginning-points arranged in circumferential rows, strips of relatively yielding material, of less width than the distance between the rows of ginning-points, secured to the cylinder between the rows, stripping-fingers extending over said strips and downwardly-projecting lips carried by said fingers at the sides of said strips.

13. In a cotton-gin, a ginning-cylinder provided with ginning-points arranged in circumferential rows, in combination with stripping-fingers provided with end portions which project circumferentially over the surface of the cylinder between the rows of ginning-points, below the ends thereof, and an adjustable bar to which said fingers are secured.

14. In a gin, the combination of a ginning-cylinder provided with ginning-points arranged in circumferential rows, stripping-fingers projecting between the rows, a bar to which said fingers are secured and means for adjusting the position of said bar vertically and longitudinally.

15. In a gin the combination of a ginning-cylinder provided with ginning-points arranged in circumferential rows, stripping-fingers projecting between the rows, a bar to which said fingers are secured and means for adjusting the position of said bar, comprising an adjusting-screw and a spring interposed between the screw and said bar.

16. In a gin the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows, of a plurality of revolvable disks, coöperating with the ginning-points, and means for presenting the cotton to the action of the ginning-points below said disks.

17. In a gin the combination with the ginning-points and means coöperating therewith to separate the lint from the seed, of a plurality of revolvable disks arranged below the inner breast adjacent to the ginning-cylinder, and means for presenting the cotton to the action of the ginning-points below said disks.

18. In a gin the combination with the ginning-points and means coöperating therewith to separate the lint from the seed, of a plurality of revolvable disks having scalloped edges arranged below the inner breast adjacent to the ginning-cylinder.

19. In a gin the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows, of a plurality of revolvable disks having scalloped edges which project between said rows.

20. In a gin, the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows, of a plurality of revolvable disks, arranged in pairs, the edges of which project between said rows, and means for presenting the cotton to the action of the ginning-points below said disks.

21. In a gin the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows, of a plurality of revolvable disks coöperating therewith, plates arranged between said disks and means for actuating said plates to engage the cotton in the gin-breast and lift it above said disks.

22. In a gin the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows, of a plurality of revolvable disks which project between said rows, plates arranged between said disks and having projections for engaging the cotton in the gin-breast and means for moving said projections above the edges of the disks.

23. In a gin the combination with a ginning-cylinder having ginning-points arranged thereon in circumferential rows of a plurality of revolvable disks which project between said rows and means for lifting the cotton in the gin-breast clear of the disks.

24. In a gin the combination with the ginning-points and means coöperating therewith to separate the seed from the lint, of means for lifting the cotton relatively to the ginning-points and retarding its rotation in the breast to arrest the ginning action without stopping the gin.

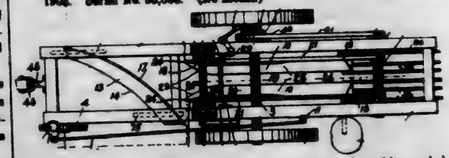
25. In a gin the combination with the ginning-points and means coöperating therewith to separate the seed from the lint, of plates at the lower portion of the inner breast and means for lifting said plates to engage the cotton in the breast for the purposes set forth.

26. In a gin the combination with the ginning-points and means coöperating therewith to separate the seed from the lint, of means for engaging the cotton in the inner breast and carrying it to the ginning-points and means for retarding the movement of the cotton in the inner breast without stopping the gin.

27. In a gin the combination with the ginning-points and means coöperating therewith to effect the separation of the seed from the lint, of revolving devices for engaging the cotton in the inner breast and carrying it to the ginning-points and means for effecting the disengagement of such cotton and said devices.

28. In a gin the combination with the ginning-points and means coöperating therewith to effect the separation of the seed from the lint, of revolving devices for engaging the cotton in the inner breast and carrying it to the ginning-points and means for lifting the cotton out of engagement with said devices.

707,097. BEET-HARVESTER. WALTER GARY, Saginaw, Mich., assignor of one-half to Burton Ostrom, Saginaw, Mich. Filed Feb. 21, 1902. Serial No. 95,082. (No model.)

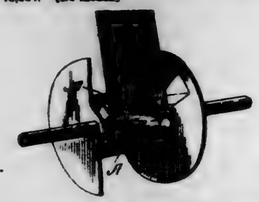


Claim.—1. In a harvester, a frame and a plow adjustably carried by said frame, the plow being formed by two inclined L-shaped parallel members separated by a parallel open space between the lower flanges, the side flanges being sharpened and the bottom flanges being cut away in front to form a point with the side flanges, substantially as shown and described.

2. In a harvester, a frame and a plow adjustably connected thereto, the front half of the plow being formed of two parallel inclined L-shaped members separated by a parallel open space between the bottom flanges, the rear portion of said members forming a V-shaped trough open at the bottom.

3. In a harvester, a plow composed of two parallel L-shaped members, with an open space between the bottom flanges, the side flanges being sharpened and the bottom flanges being cut on a curve in front to form a point with the side flanges, the rear portion of said members being shaped so as to form a V-shaped trough open at the bottom and having openings in the sides for relieving the plow of surplus earth, substantially as shown and described.

707,098. RIBBON-FASTENER FOR TYPE-WRITING MACHINES. FRANK O. GARRISON, Portland, Oreg. Filed Aug. 31, 1901. Serial No. 73,867. (No model.)

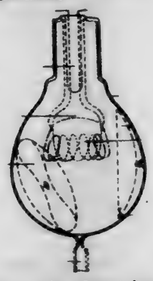


Claim.—1. A fastener for type-writer ribbons, comprising a substantially circular band, one of the ends of which is provided with inwardly and rearwardly extending spurs near its tip or extremity, substantially as described.

2. A fastener for type-writer ribbons comprising a substantially circular band, one of the ends of which is provided with three inwardly and rearwardly extending spurs, said spurs being at a distance from the tip, and the center one being farther from the tip than the other two.

3. In a type-writer-ribbon holder, a spool, and a substantially circular band thereon, the ends of the band being normally at a distance from each other, and one of them provided at a distance from its tip with inwardly and rearwardly extending spurs adapted to engage with the ribbon and hold it upon the spool.

707,099. INCANDESCENT ELECTRIC LAMP. EDGAR S. GARDNER, Boston, Mass., assignor to Bernstein Electric Manufacturing Company, Portland, Me., a Corporation of Maine. Filed July 23, 1901. Serial No. 69,168. (No model.)



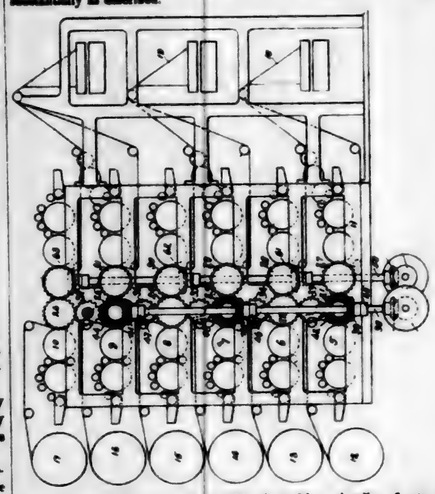
Claim.—1. An improved incandescent lamp consisting of an exhausted bulb a filament, leading-in wires supporting said filament, a glass tube extending into the exhausted bulb and sealed at the outer end to the neck of said bulb and at its inner end about the wires which support the filament, and a reflector inserted into the bulb before the neck is sealed and secured to the inside of said bulb and opposite the filament.

2. An improved incandescent lamp consisting of an exhausted bulb a filament, leading-in wires supporting said filament, a glass tube extending into the exhausted bulb and sealed at the outer end to the neck of said bulb and at its inner end about the wires which support the filament, and a reflector inserted into the bulb before the neck is sealed and secured to the inside of said bulb and lengthwise to it and opposite the filament.

707,100. PRINTING MACHINERY. SAMUEL G. GOSS, Chicago, Ill., assignor to the Goss Printing Press Company, Chicago, Ill., a Corporation of Illinois. Filed Jan. 16, 1897. Serial No. 619,423. (No model.)

Claim.—1. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving mechanisms operable independently of each other to drive the same set or sets of printing mechanism, substantially as described.

2. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of independent driving mechanisms adapted to operate independently to drive the same set or sets of printing mechanism, and means for coupling said driving mechanisms together, substantially as described.



3. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another in a common frame, of a plurality of independent driving mechanisms, and means for driving certain of said sets of printing mechanisms by one of said driving mechanisms and certain of the same sets of printing mechanism by another of said driving mechanisms, substantially as described.

4. In a printing-press the combination with a plurality of sets of printing mechanism arranged one above another in a common frame, of a plurality of independent driving mechanisms, means for driving certain of said sets of printing mechanism by one of said driving mechanisms and one of the same sets of printing mechanism by another of said driving mechanisms and means for coupling said driving mechanisms together, substantially as described.

5. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving mechanisms independent of each other, means for driving certain of said sets of printing mechanism by one of said driving mechanisms and certain other of said sets of printing mechanism by another of said driving mechanisms, and means whereby the different sets of printing mechanism may be connected to the different driving mechanisms or disconnected therefrom, as may be desired, substantially as and for the purpose specified.

6. In a printing-press the combination with a plurality of sets of printing mechanism, of a plurality of independent driving mechanisms adapted to operate independently to drive the same set or sets of printing mechanism, means for coupling said driving mechanisms together, and folding devices adapted to operate in connection with the different sets of printing mechanism, substantially as described.

7. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving mechanisms independent of each other, means for driving certain of said sets of printing mechanism by one of said driving mechanisms and certain other of said sets of printing mechanism by another of said driving mechanisms, and means for driving all of said sets of printing mechanism by one of said driving mechanisms, substantially as described.

8. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving mechanisms operable independently of each other to drive the same set or sets of printing mechanism and a plurality of folding devices adapted to operate independently or together and in connection with one or more of the sets of printing mechanisms, substantially as described.

9. In a printing-press the combination with a plurality of sets of printing mechanism, of driving devices at each side of the press and independent driving-shafts for driving the same set or sets of printing mechanism from opposite sides of the press, substantially as described.

10. In a printing-press, the combination with a plurality of sets of printing mechanism, of driving-gears located at opposite sides of the press for driving said sets of printing mechanism from either side of the press and independent driving-shafts for communicating power to the driving gears at the opposite sides of the press, substantially as described.

11. In a printing-press, the combination with three or more sets of printing mechanism, of means whereby said sets of printing mechanisms may be connected together or disconnected from one another, beveled gears carried by alternate sets of printing mechanism at opposite sides of the press, and independent driving-shafts geared with said beveled gears, whereby the gears at each side of the press may be rotated at will, substantially as and for the purpose specified.

12. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving mechanisms operable independently of each other, and means for driving one or more of said sets of printing mechanism by either of said driving mechanisms independently of the operation of the other set or sets of printing mechanism, substantially as described.

13. In a printing-press, the combination with three or more sets of printing mechanism, and means whereby said sets of printing mechanism may be connected together or disconnected from one another, of a pair of driving-shafts, and means carried by said shafts and engaging alternate sets of printing mechanism for driving said sets of printing mechanism, substantially as described.

14. In a printing-press, the combination with three or more sets of printing mechanism, and means whereby said sets of printing mechanism may be connected together or disconnected from one another, of a pair of driving-shafts, means carried by said shafts and engaging alternate sets of printing mechanism for driving said sets of printing mechanism, and means for driving said driving-shafts from a common source of power, substantially as described.

15. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of driving-mechanisms operable independently of each other, and means for driving any one of said sets of printing mechanism by either of said driving mechanisms independently, substantially as described.

16. In a printing-press, the combination with a plurality of sets of printing mechanism, of a plurality of independently-operable driving-shafts, means for driving the same set or sets of printing mechanism from either of said driving-shafts, and coupling devices for coupling said shafts together, substantially as described.

17. In a printing-press the combination of two sets of printing mechanisms, two driving mechanisms and connections between each of said driving mechanisms and both sets of printing mechanism, the two driving mechanisms being independent of each other whereby either driving mechanism may be employed independently of the other to drive said sets of printing mechanism, substantially as described.

18. In a printing-press the combination of two sets of printing mechanism arranged one above the other in a common frame, two independent driving mechanisms and means for driving one of said sets of printing mechanism by one of said driving mechanisms and the other of said sets of printing mechanism by the other driving mechanism and means for driving both sets of printing mechanism by one of said driving mechanisms, substantially as described.

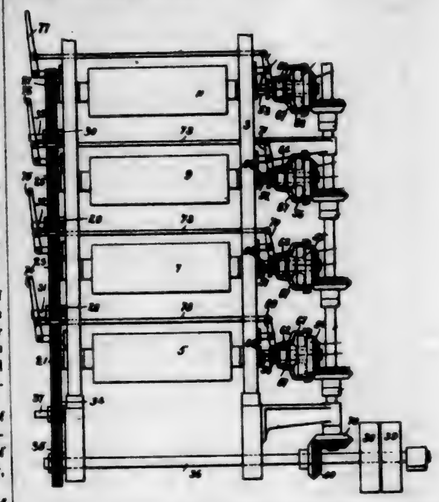
19. In a printing-press the combination with a plurality of sets of printing mechanism mounted in a common frame, of a plurality of driving mechanisms independent of each other, means for driving certain of said sets of printing mechanism by one of said driving mechanisms and certain of the same sets of printing mechanism by another of said driving mechanisms and a plurality of folding mechanisms, substantially as described.

20. In a printing-press the combination with a plurality of sets of printing mechanism mounted in a common frame, of a plurality of independent driving mechanisms adapted to operate independently of each other, means for driving certain of said sets of printing mechanism by one of said driving mechanisms and certain of the same sets of printing mechanism by another of said driving mechanisms, means for coupling said driving mechanisms together so that they will operate jointly to drive said sets of printing mechanism and a plurality of feeding mechanisms adapted to receive webs from said sets of printing mechanism, substantially as described.

21. In a printing-press, the combination with three or more sets of printing mechanism, and means whereby said sets of printing mechanism may be connected together or disconnected from one another, of two driving-shafts arranged substantially as described for driving said sets of printing mechanism, and means for connecting said shafts with common driving mechanism or for disconnecting them, substantially as described.

707,101. PRINTING-PRESS. SAMUEL G. GOSS, Chicago, Ill., assignor to the Goss Printing Press Company, Chicago, Ill., a Corporation of Illinois. Filed Apr. 26, 1897. Serial No. 633,491. (No model.)

Claim.—1. In a printing-press, the combination with a plurality of sets of printing mechanism mounted one above another in a common frame, of a common source of power for driving said sets of printing mechanism, and means for starting and stopping one of said sets of printing mechanism independently of the other and while each other is in motion, substantially as described.



2. In a printing-press, the combination with a plurality of sets of printing mechanism mounted one above another in a common frame, of a common source of power for driving said sets of printing mechanism, means for coupling together certain of said sets of printing mechanism, and means for starting and stopping such coupled sets of printing mechanism simultaneously and independently of the condition of the other set or sets of printing mechanism composing the press as a whole, substantially as described.

3. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a driving-shaft, independently-operable devices for connecting each of said sets of printing mechanism to said driving-shaft while said shaft is in motion, and mechanism independent of said connecting devices for driving said sets of printing mechanism from said driving-shaft, substantially as described.

4. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a driving-shaft, a clutch operable while the shaft is in motion for connecting one of said sets of printing mechanism to said shaft, and coupling mechanism for coupling a plurality of said sets of printing mechanism together, whereby a plurality of sets of printing mechanism may be started by operating said clutch, substantially as described.

5. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a drive-shaft, a clutch operable while the shaft is in motion for connecting one of said sets of printing mechanism to said shaft, and gears for coupling a plurality of said sets of printing mechanism together, substantially as described.

6. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, and a series of gears connecting said sets of printing mechanism together in series, certain of said gears being movable out of engagement with other gears of the series to permit independent operation of certain of said sets of printing mechanism, of a driving-shaft, means for driving said gears from said driving-shaft, independent coupling devices for coupling said sets of printing mechanism independently to said driving-shaft, and means for operating said coupling devices while said shaft is in motion, substantially as described.

7. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, and a series of gears connecting said sets of printing mechanism together in series, certain of said gears being movable out of engagement with other gears of the series to permit independent operation of certain sets of printing mechanism, of a driving-shaft, means for driving said gears from said driving-shaft, a vertical driving-shaft, means for driving said latter shaft, a series of coupling devices independent of said gears between said vertical shaft and the sets of printing mechanism, and levers for operating said coupling devices independently of one another, substantially as described.

8. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a horizontal driving-shaft, a vertical driving-shaft arranged on one side of the press, a series of beveled pinions carried by said vertical shaft, a series of friction-clutches carried by said sets of printing mechanism and having beveled pinions adapted to mesh with said beveled pinions carried by said vertical shaft, means for operating said friction-clutches to connect and disconnect said sets of printing mechanism with said vertical shaft, and means independent of said clutches for coupling together a plurality of said sets of printing mechanism, substantially as described.

9. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a horizontal driving-shaft, a vertical driving-shaft arranged on one side of the press, a series of beveled pinions carried by said vertical shaft, a series of clutches carried by said sets of printing mechanism and having beveled pinions adapted to mesh with said beveled pinions carried by said vertical shaft, means for operating said clutches to connect and disconnect said sets of printing mechanism with said vertical shaft, a series of working gears for driving said sets of printing mechanism, adjustable intermediate pinions for connecting said sets of printing mechanism in series and for disconnecting them, and means for driving said gears from the horizontal driving-shaft, substantially as described.

10. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a horizontal driving-shaft, a series of working gears carried by said sets of printing mechanism at one side of the press, adjustable intermediate pinions for connecting said gears in series and for disconnecting them, a vertical shaft, means for driving said vertical shaft, a series of independent clutches connected to said sets of printing mechanism, and means whereby said clutches may be operated to connect them with said vertical shaft, substantially as described.

11. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a driving-shaft, independently-operable devices for connecting certain of said sets of printing mechanism to said driving-shaft while said shaft is in motion, a lever for operating each of said connecting devices, and means independent of said drive-shaft for coupling together certain of said sets of printing mechanism, whereby a plurality of sets of printing mechanism may be simultaneously connected to said drive-shaft by operating a single lever, substantially as described.

12. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a vertical driving-shaft, independent coupling devices for each of said sets of printing mechanism, and means for operating said coupling devices to connect or disconnect each of said sets of printing mechanism from said vertical driving-shaft while said shaft is in motion independently of the other sets of printing mechanism, substantially as described.

13. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a vertically-arranged driving-shaft, a series of independently-operating friction-clutches for independently connecting and disconnecting said sets of printing mechanism and said driving-shaft, and levers for operating said friction-clutches, substantially as described.

14. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a driving-shaft, independently-operable friction-clutches for connecting certain of said sets of printing mechanism to said drive-shaft while said shaft is in motion, a lever for operating each of said clutches, and gears for coupling together certain of said sets of printing mechanism, whereby a plurality of sets of printing mechanism may be simultaneously connected to said drive-shaft by operating a single lever, substantially as described.

15. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of means for starting and stopping different sets of printing mechanism independently, means for coupling together certain of said sets of printing mechanism, a plurality of folding mechanisms arranged one above another, and means for driving said folding mechanisms independently of one another and in combination with different sets of printing mechanism, substantially as described.

16. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a driving-shaft, independent clutches for driving said sets of printing mechanism from said shaft, means independent of said shaft for connecting certain of said sets of printing mechanism together, whereby a plurality of sets of printing mechanism may be started by operating a single clutch, and folding mechanism operating in connection therewith, substantially as described.

17. The combination with a set of printing mechanism, of a plurality of folding mechanisms, and means for operating said folding mechanisms independently of one another from and in combination with the printing mechanism, substantially as described.

18. The combination with a plurality of sets of printing mechanism, of a folding device, and means for driving said folding device from, and in combination with, different sets of printing mechanism operating separately, substantially as described.

19. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, and a series of gears connecting said sets of printing mechanism together in series, certain of said gears being movable out of engagement with other gears of the series to permit independent operation of certain of said sets of printing mechanism, of a driving-shaft, independent connecting devices for connecting certain of said sets of printing mechanism independently to said drive-shaft, said connecting devices being operable while said shaft is in motion, substantially as described.

20. In a printing-press, the combination with a plurality of sets of printing mechanism arranged one above another, of a vertical driving-shaft, a series of beveled pinions carried by said shaft, friction-clutches carried by certain of said sets of printing mechanism and having beveled pinions adapted to mesh with said beveled pinions carried by said shaft, means for operating said friction-clutches to connect and disconnect said sets of printing mechanism and said shaft, and means independent of said shaft for coupling together a plurality of said sets of printing mechanism, substantially as described.

21. In a printing-press the combination of three or more sets of printing mechanism arranged one above another in a common frame and capable of operation as distinct and independent presses, means for coupling together certain of said sets of printing mechanism and means for starting and stopping said coupled sets and the other set or sets of printing mechanisms independently of each other, substantially as described.

22. In a printing-press the combination of a plurality of sets of printing mechanism, means for starting and stopping certain sets of printing mechanism independently, a plurality of folding mechanisms and means for driving said folding mechanisms independently of each other and in combination with different sets of printing mechanism, substantially as described.

707,102. NUT-LOCK. WILLIAM GRAHAM, Dekoven, Ky. Filed Oct. 29, 1901. Serial No. 80,396. (No model.)

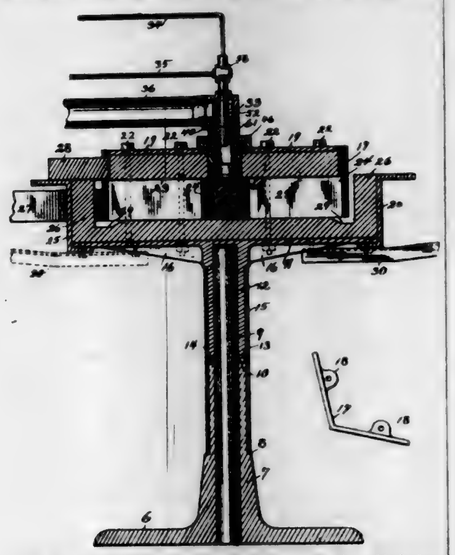
Claim.—1. A bolt and a nut, the one provided with a longitudinal groove and the other with a longitudinal groove arranged in a plane eccentric to the axis of the bolt and sloping in the direction in which the nut turns when being screwed home; in combination with a key adapted to be inserted into said grooves when they register, said key being made angular in cross-section to correspond to the angularity of the registering grooves and adapted, by a retrograde movement or turn of the nut, to be forced firmly into binding contact, substantially as set forth.

2. The combination with a bolt provided with a longitudinal groove arranged in a plane eccentric to the axis of the bolt, of a nut provided with a longitudinal groove arranged in a plane eccentric to the axis of the nut and at an angle to the first-named groove and sloping in the direction in which the nut turns when being screwed home, whereby when the groove of the nut is made to register with the groove of the bolt, the outline of the groove will be angular, and a key angular in cross-section to correspond with the angularity of the registering grooves, substantially as set forth.

707,108. FURNACE. ROBERT HALLEY, Chicago, Ill., assignor of one-fourth to the Flame Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 2, 1901. Serial No. 70,568. (No model.)

Claim.—1. In a device of the class described, the combination with the stationary support, of a furnace mounted to rotate thereon having the small central open portion and the passages radiating therefrom and leading to the outside of the furnace, supports for the articles to be heated adjacent to the openings terminating the passages, and a burner axially located with reference to said furnace and adapted to discharge the flame into said open central portion against a solid opposed wall by which it is deflected into said passages: substantially as and for the purpose described.

2. In a device of the class described, the combination with the stationary support, of a furnace mounted to rotate thereon having the small central open portion and the passages radiating therefrom and leading to the outside of the furnace, supports for the articles to be heated adjacent to the openings terminating the passages, and a stationary burner having oil and air supply pipes connected thereto and by which it is supported axially located in said furnace and adapted to discharge the flame into said open central portion against a solid opposed wall by which it is deflected into said passages; substantially as and for the purpose described



3. In a device of the class described, the combination with the base having the vertical shaft 9 therein, of the bottom plate 11 having the sleeve on the under side thereof rotating upon the shaft 9, the top plates 19, the angle-irons 17 bolted between said bottom and top plates and forming the apertures 24 of the burner located in the center of the top plates.

4. In a device of the class described, the combination with the base having the vertical shaft thereon, of the furnace adapted to rotate on the vertical shaft, the radial arms 30 secured to said furnace, the ring 32 secured to said arms, and the burner centrally mounted in the top of the furnace, substantially as described.

5. In a device of the class described, the combination with the burner of the furnace into which the flame of the burner is directed having the peripheral apertures, a support to hold articles adjacent to the apertures, and the fire-bricks cut away as at 29 to permit the flames to pass between said articles, substantially as and for the purpose described.

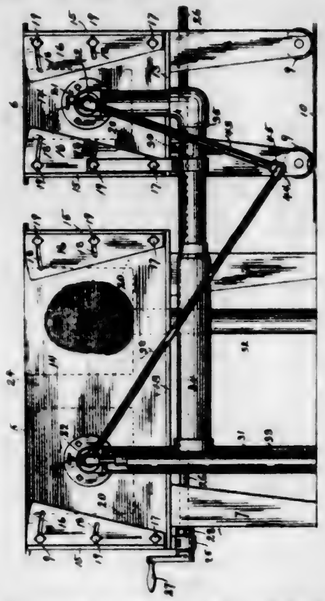
6. In a device of the class described, the combination with the furnace-body having the peripheral apertures, of the Z portions 25 secured to the bottom of the furnace-body opposite said apertures to support the fire-bricks in front and on top of said apertures, substantially as described.

7. In a device of the class described, the combination with the block having the channel therethrough of a burner adapted to discharge a stream of oil through said channel, and a series of openings in said block having their points meeting in the said channel in the line of discharge of the stream of oil, substantially as and for the purpose described.

707,104. ADJUSTABLE FURNACE. ROBERT HALLEY, Chicago, Ill., assignor of one-fourth to the Flame Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 2, 1901. Serial No. 70,569. (No model.)

Claim.—1. In a furnace, the combination with the stationary furnace member, of the movable furnace member, said members having the surfaces upon which the articles to be heated are placed in substantially the same plane, adjustable oil and air pipe connections between said members, and means for moving said movable member in the plane of the said surfaces so that the articles can be heated at points different distances apart, substantially as described.

2. In a furnace, the combination with the furnace member having a burner at one end thereof and the oil-pipe and air-pipe leading to the said burner, of the movable furnace member having a burner at one end thereof, the heating-surfaces of said members upon which the articles to be heated are placed being in substantially the same plane, the adjustable oil and air pipe connections between the air and oil pipes of the burner on the stationary member and the burner on the adjustable member, and means for moving said movable member in the plane of the said surfaces so that the articles can be heated at points different distances apart: substantially as described.



3. In a furnace, the combination with the stationary furnace member having a burner at one end thereof, and the air-pipe and oil-pipes leading to said burner, of the movable furnace member having a burner at one end thereof, the telescoping air-pipe connections between the burner on the movable member and the air-pipe for the stationary member, and the pipes 38 and 43 pivotally connected at both ends thereof between the oil-pipe on the stationary member and the burner on the movable member, all coöperating substantially as and for the purpose described.

4. In a furnace, the combination with the stationary furnace member, of the movable furnace member, burners for each of said members adjustable oil and air pipe connections between said members, and means for adjusting the movable member relative to the stationary member consisting of the screw-threaded rod secured to rotate in one of said members and coöperating with the screw-threaded aperture in the other of said members.

5. In a furnace, the combination with the stationary furnace member, of the movable furnace member mounted on rollers, adjustable oil and air pipe connections between said members, and means for adjusting the movable member consisting of the screw-threaded rod secured to rotate in one of said members and coöperating with the screw-threaded aperture in the other of said members.

6. In a furnace, the combination with the base-plate, of the stationary ends, and sides pivotally secured at their lower ends to the base-plate to increase or diminish the breadth of the furnace-top.

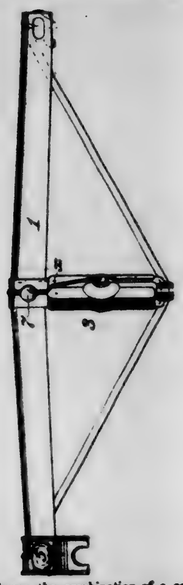
7. In a furnace, the combination with the base-plate, of the stationary ends, the sides provided with the segmental flanges overlapping the ends and pivoted thereto at their lower ends, and means for securing the sides in any desired position of adjustment.

8. In a furnace, the combination with the base-plate, of the stationary ends, the sides provided with the segmental flanges overlapping the ends and pivoted thereto at their lower ends, and means for securing the sides in any desired position of adjustment, consisting of the segmental slots in said flanges concentric with the pivotal points thereof and the bolts 19 passing through said slots into the ends substantially as and for the purpose described.

9. A furnace of the class described, having a rectangular fire-box with an oil-burner located so as to direct the flame inwardly from one end near one side, and another similar burner located so as to direct the flame inwardly from the other end near the other side, and adapted to have a temporary wall extending between the center of the ends.

707,105. BRAKE-BEAM. BRONISLAW HASKELL, Saginaw, Mich. Filed June 18, 1902. Serial No. 112,142. (No model.)

Claim.—1. In a brake-beam, the combination of a compression member of U or channel section, a tension member having hooked ends fitting between the side plates of the compression member, transverse connections, passing through the eyes of the hooked ends of the tension member and through the side plates of the compression member, and a strut interposed between the middle portions of the compression and tension members.



2. In a brake-beam, the combination of a compression member of U or channel section, a tension member having hooked ends fitting between the side plates of the compression member, transverse connections which are elongated in cross-section in the line of the compression member, and which pass through correspondingly-formed slots in the side plates of said member and through the eyes of the hooked ends of the tension member, and a strut interposed between the middle portions of the compression and tension members.

3. In a brake-beam, the combination of a compression member of U or channel section, a tension member having hooked ends fitting between the side plates of the compression member, brake-heads fitting over the ends of the compression member, transverse connections passing through the brake-heads, the side plates of the compression member, and the eyes of the hooked ends of the tension member, and a strut interposed between the middle portions of the compression and tension members.

4. In a brake-beam, the combination of a compression member of U or channel section, a tension member, having hooked ends fitting between the side plates of the compression member, brake-heads fitting over the ends of the compression and tension members, rivets passing through the brake-heads, the side plates of the compression member, and the eyes of the hooked ends of the tension member, and having heads abutting on the brake-heads, and a strut interposed between the middle portions of the compression and tension members.

707,106. WINDOW-SASH. ERNEST HINCK, Yannechine, Ontario. Filed Feb. 28, 1902. Serial No. 96,661. (No model.)

Claim.—1. The combination of a window-casing provided with pulley-pieces, sash-beads consisting of a fixed piece and a movable piece, a sash mounted to reciprocate between said beads, the movable piece being slidably mounted in oblique guides on the fixed piece and adapted to be pushed back to free the corresponding edge of the sash, and partible hinges carried by the sash and the window-casing about which the sash is adapted to turn.

2. The combination of a window-casing having sash slides or beads, a sash mounted to reciprocate therein between said slides, counterbalancing means removably attached to said sash and comprising a weight having a cord passing over a pulley, hinge-halves attached respectively to the casing and sash at one edge of the latter and about which it is adapted to be turned, means for releasing the opposite edge of the sash from its corresponding slide, means for releasing said counterbalancing means from the free end of the sash, and means operated by the movement of the sash-slide to lock said counterbalancing means in position.

3. The combination of a window-casing having slides the inner one of which at one side has a sliding piece adapted to have an oblique reciprocating movement and be pushed back flush with the casing-board, a set of oblique cam-shaped guides confining said sliding piece in its movement, a sash mounted to slide between said slides, and hinge-halves adjacent to one edge of the sash on the opposite side from said sliding piece, whereby the sash is adapted to be released from the slide at one side by pushing said slide up or down and to turn about the hinges at the opposite side.

4. The combination of a window-casing having sash-slides, a sash mounted to slide therebetween, hinge-sockets mounted in the window-casing adjacent to one edge of the sash, pintles carried by the edge of the sash adapted to engage in said sockets, a sliding piece forming a part of one of said sash-slides and adapted to be pushed back flush with the casing, means for counterbalancing said sash, said means being removable from said sash at one side thereof, and means operated by the movement of said sliding piece to lock said counterbalancing means in position.

5. In a combination sash and casing for a window, a sash-slide comprising a fixed piece, a removable piece having an oblique cam-slot therein, and a sliding piece having a tongue adapted to work in said cam-slot and a lower end guided obliquely by suitable guides upon the casing, whereby the raising of said sliding piece will cause it to be moved forward to act as a guide for the sash and the lowering of said sliding piece will cause it to be pushed back flush with the casing.

6. In a combination sash and casing for a window, a sash-slide comprising a fixed piece, a removable piece having an oblique cam-slot therein, and a sliding piece having a tongue adapted to work in said cam-slot and a lower end guided obliquely by suitable guides upon the casing, whereby the raising of said sliding piece will cause it to be moved forward to act as a guide for the sash and the lowering of said sliding piece will cause it to be pushed back flush with the casing, in combination with a second sash-slide, a sash mounted to reciprocate between the two slides, and partible hinges carried by the sash and window-casing to enable it to turn about the opposite edge thereof.

7. In a combination sash and casing for a window, a sash-slide comprising a fixed piece, a removable piece having an oblique cam-slot therein, and a sliding piece having a tongue adapted to work in said cam-slot and a lower end guided obliquely by suitable guides upon the casing, whereby the raising of said sliding piece will cause it to be moved forward to act as a guide for the sash and the lowering of said sliding piece will cause it to be pushed back flush with the casing, in combination with a second sash-slide, a sash mounted to reciprocate between the two slides, partible hinges carried by the sash and window-casing to enable it to turn about the opposite edge thereof, counterbalancing means consisting of a sash-cord, a pulley over which the cord passes, and a weight attached to the end thereof, and an attachment-piece for removably connecting the sash with said cord comprising a rod sliding in a suitable groove in the casing and having a tongue with a notch in the stile of the sash.

8. In a combination sash and casing for a window, a sash-slide comprising a fixed piece, a removable piece having an oblique cam-slot therein, and a sliding piece having a tongue adapted to work in said cam-slot and a lower end guided obliquely by suitable guides upon the casing, whereby the raising of said sliding piece will cause it to be moved forward to act as a guide for the sash and the lowering of said sliding piece will cause it to be pushed back flush with the casing, in combination with a second sash-slide, a sash mounted to reciprocate between the two slides, partible hinges carried by the sash and window-casing to enable it to turn about the opposite edge thereof, counterbalancing means consisting of a sash-cord, a pulley over which the cord passes, and a weight attached to the end thereof, an attachment-piece for removably connecting the sash with said cord comprising a rod sliding in a suitable groove in the casing and having a tongue with a notch in the stile of the sash, and means operated by the movement of said sliding piece to lock said attachment-piece comprising a pivoted latch adapted to be pushed by means of a cam edge on the sliding piece into engagement with a reduced portion of said attachment-piece.

9. The combination of a window-casing, sash slides or beads attached thereto and one of which has a sliding piece guided to move in an obliquely upward and downward direction, means for raising said sliding piece to a position overlapping the sash and for lowering it to position clearing the sash, a sash mounted to reciprocate between said slides, hinge-pieces mounted upon the opposite side of the casing adjacent to the sash, coöperating hinge-pieces mounted on the sash and adapted to engage with said fixed hinge-pieces, counterbalancing means for one side of the sash comprising a sash-cord passing over a pulley and a weight attached at the end thereto, a disconnectible attachment-piece to which the other end of the sash-cord is connected, said attachment-piece having a lug or tongue engaged by a notch in the edge of the sash-stile, and a sector-shaped latch pivotally mounted on the window-casing between said sliding piece and said attachment-piece, said sliding piece having an oblique cam-face adapted to operate said latch to cause it to engage with a reduced portion of said attachment-piece when the sliding piece is pushed downwardly and inwardly, whereby to lock said attachment-piece in position.

10. In a combination window sash and casing, a partible hinge comprising a stationary socket, a pivoted metallic plate carrying a pintle, and an adjusting-screw passing through an arcuate slot in said plate, whereby the same may be tightened to the requisite degree.

11. In a combination sash and casing, hinge means for permitting the sash to be turned about a vertical axis comprising a stationary socket attached to the casing, and a plate pivoted to the sash-stile and having an arcuate slot therein, an adjusting-screw passing through said slot, a pintle carried by said plate and adapted to be engaged by said socket when the plate is in one position and to be out of the way of said socket when the plate is turned to another position, and a thumb-piece projecting from said plate by which the latter may be turned.

12. In a combination sash and casing, hinge means for permitting the sash to be turned about a vertical axis comprising a stationary socket attached to the casing, and a plate pivoted to the sash-stile and having an arcuate slot therein, an adjusting-screw passing through said slot, a pintle carried by said plate and adapted to be engaged by said socket when the plate is in one position and to be out of the way of said socket when the plate is turned to another position, and a double-faced cam-piece attached to the casing of the window and adapted to strike said pivoted plate when the sash is moved past it to push said pintle out of position to be engaged by said socket, substantially as described.

707,107. PROCESS OF TREATING ORES. JOHN HERMAN, Canon City, Colo. Filed Mar. 26, 1902. Serial No. 100,457. (No specimens.)

Claim.—1. The process described which consists in roasting sulfid-of-copper ore at a low heat to form sulfates of the copper and some of the iron present, and produce a large percentage of ferrous sulfate, leaching the roasted ore, precipitating the metallic copper, and adding salt to the leaching solution, before or after the precipitation of the metallic copper, whereby the ferrous salts in the solution are converted to the chlorid and a solution having an excess of salt is produced, and the said solution is adapted to dissolve copper and silver out of carbonate and oxid ores.

2. The process described which consists in roasting sulfid-of-copper ore at a low heat to form sulfates of the copper and some of the iron present and produce a large percentage of ferrous sulfate, leaching the roasted ore, precipitating the metallic copper with iron scraps whereby the proportion of ferrous sulfate is increased, and adding salt to the leaching solution, before or after the precipitation of the metallic copper, whereby the ferrous salts in the solution are converted to the chlorid and a solution having an excess of salt is produced, and the said solution is adapted to dissolve copper and silver out of carbonate and oxid ores.

3. The process described which consists in roasting sulfid-of-copper ore at a low heat to form sulfates of the copper and some of the iron present, and produce a large percentage of ferrous sulfate, leaching the roasted ore, precipitating the metallic copper, adding salt to the leaching solution, before or after the precipitation of the metallic copper to convert the ferrous salts in the solution to the chlorid and a solution having an excess of salt is produced, leaching carbonate and oxid ores with the solution, and precipitating the metallic copper therefrom.

4. The process described which consists in roasting sulfid-of-copper ore at a low heat to form sulfates of the copper and some of the iron present, and produce a large percentage of ferrous sulfate, leaching the roasted ore, roasting the residue from the leaching in the presence of common salt, leaching the roasted residue with a salt solution, precipitating the metallic copper from the solutions, and commingling the two solutions before or after the precipitation of the metallic copper for the purpose described.

707,108. CAR-COUPLING. PHILLIP HIER, Chicago, Ill. Filed Sept. 16, 1901. Serial No. 75,608. (No model.)

Claim.—1. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin for said knuckle, means located on the opposite side of the locking-pin from the tail of the knuckle when the latter is in its closed position and engaged by the locking-pin when it is elevated and moved thereby into position beneath the pin to support the same, substantially as described.

2. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin, a dog pivotally supported on the opposite side of the pin from the tail of the knuckle when the latter is in its closed position engaged by the locking-pin when it is elevated and swung thereby into position beneath the pin to support the same, substantially as described.

3. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin for said knuckle having a vertical groove therein, a dog pivotally supported within the coupler-head on the opposite side of the pin from the tail of the knuckle when the latter is in its closed position, a lug on said dog projecting into said groove, whereby when the locking-pin is elevated the dog is swung through the engagement of the end of the groove with said lug into position beneath the pin to support the same, substantially as described.

4. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin for said knuckle, a dog pivotally supported within the coupler-head engaged by the locking-pin when it is elevated and swung thereby into position to support the pin, and a finger projecting from said dog through an opening in the coupler-head, whereby the dog may be manually swung out of engagement with the pin, substantially as described.

5. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin for said knuckle, a dog pivotally supported within said coupler-head adapted to be engaged by the locking-pin when it is elevated and swung thereby into position to support the pin, said dog projecting into the path of the tailpiece of the knuckle and adapted to be engaged thereby and removed from beneath the locking-pin when the knuckle is swung from its closed to its open position, a finger projecting from said dog through an opening in the coupler-head whereby the dog may be manually swung out of engagement with the pin, substantially as described.

6. In a car-coupler, the combination with a coupler-head, of a knuckle pivotally supported therein, a locking-pin for said knuckle having a vertical groove therein, a dog pivotally supported within the coupler-head having a lug projecting into said groove and adapted to be engaged by the lower end thereof when the locking-pin is elevated and thereby swung into position to support the pin, said dog projecting into the path of the tailpiece of the knuckle and adapted to be engaged thereby and removed from beneath the locking-pin when the knuckle is swung from its closed to its open position, and a finger projecting from said dog through an opening in the coupler-head whereby the dog may be manually swung out of engagement with the pin, substantially as described.

707,109. TEMPLE-ATTACHING DEVICE. FRANKLIN G. HIBBS, Philadelphia, Pa. Filed Oct. 17, 1901. Serial No. 78,916. (No model.)

Claim.—1. In a device of the character described, straps movably connected to clamp the lens, a temple-bar connected with one of said straps and engaging the other strap to operate the same.

2. In a device of the character described, a body portion, a strap rigidly secured to the body portion, a second strap pivotally attached thereto, a temple-arm pivoted to said body portion, and means on said arm for operating said pivoted strap.

3. In a device of the character described, a body portion, a strap rigidly secured thereto, a strap pivoted to said body portion, an arm pivoted to said body portion, and shoulders on said arm adapted to contact with said pivoted strap for operating the same.

4. In a device of the character described, a body portion, a strap attached thereto, a second strap pivoted thereto, a spring-arm on said pivoted strap, a temple-arm pivoted to said body portion, and shoulders on said temple-arm adapted to engage said spring-arm.

5. In a device of the character described, a body portion, a strap secured thereto, a second strap pivotally attached to said body portion, a temple-bar pivoted to said body portion, and means whereby said second-mentioned strap may be operated by said temple-bar.

6. In a device of the character described, a body portion, a strap secured thereto, a second strap pivotally attached to said body portion, and a temple-bar pivoted to said body portion and having means engaging with said second-mentioned strap to operate the same.

7. In a device of the character described, straps movably connected, to clamp the lens, a plate pivotally connected with one of said straps and engaging the other to operate the same, means for locking said plate in position and a temple-bar connected with said plate.

8. In a device of the character described, a body portion, a strap secured thereto, a second strap pivotally attached to said body portion, a plate pivoted to said body portion and engaging said second-mentioned strap to operate the same, and a temple-bar pivoted to said plate.

9. In a device of the character described, a body portion, a strap secured thereto, a second strap pivotally attached to said body portion, a plate pivoted to said body portion and engaging said second-mentioned strap to operate the same, a spring-arm adapted to engage said plate and lock the same in position and a temple-arm pivoted to said plate.

10. In a device of the character described, a body portion, a strap rigidly secured to said body portion, a second strap pivotally attached thereto, means for adjusting the position of said second-mentioned strap with respect to said body portion, a temple-arm pivoted to said body portion, and means on said arm for operating said pivoted strap.

11. In a device of the character described, a body portion, a strap attached thereto, a second strap pivoted thereto, a spring-arm on said pivoted strap, a temple-arm pivoted to said body portion, means on said temple-arm for operating said spring-arm and pivoted strap and a stop for limiting the movement of said spring-arm and pivoted strap.

12. In a device of the character described, straps movably connected to clamp the lens, a pivoted plate connected with one of said straps and engaging the other to operate the same, means for locking said plate in operative position and a temple-arm pivoted to said plate, whereby said temple-arm can be moved without moving said plate.

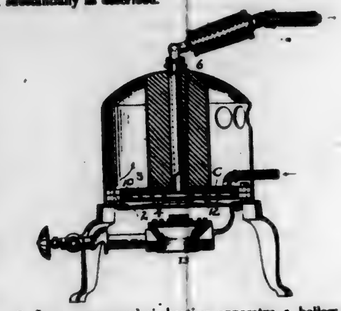
707,110. GLYCOLIC MENTHYL ESTER. FRITZ HOFMANN and JÜRGEN CALLSEN, Elberfeld, Germany, assignors to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Filed Apr. 30, 1902. Serial No. 105,308. (Specimens.)

Claim.—The herein-described new glycolic menthyl ester having the formula

representing white lustrous needles melting at 87° centigrade, which are only sparingly soluble in water and readily soluble in most organic solvents, being split up into menthol and glycolic acid when reacted upon by caustic alkalies or alkaline carbonates and exhibiting valuable therapeutic properties, substantially as hereinbefore described.

707,111. COMPRESSED-AIR-HEATING APPARATUS. GEORGE W. HOPKINS, Cleveland, Ohio, assignor to the Terry Heater Company, Cincinnati, Ohio, a Corporation. Filed Apr. 10, 1902. Serial No. 102,196. (No model.)

Claim.—1. In a compressed-air-heating apparatus, a hollow air-confining member having inlet and outlet pipes, a delivery-tube for the air connected with said outlet-pipe and comprising jointed sections, a discharge-tip of non-heat-radiating material at the end of said delivery-tube, and means to heat the air in its passage through said hollow member, substantially as described.

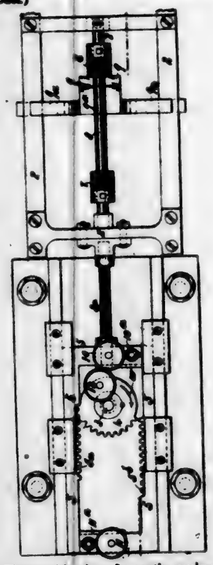


2. In a compressed-air-heating apparatus, a hollow air-confining member having an inlet and an outlet, an air-delivery tube attached to said outlet comprising rotatable and jointed sections, a protecting hand grip and cover on said tube, a removable vulcanized-fiber discharge-tip at the end of said tube, and means to heat the air in its passage through said hollow member, substantially as described

3. In a compressed-air-heating apparatus, a hollow air heating and confining member having an air-inlet pipe and an outlet-pipe at its center provided with a non-heat-conducting covering, and an inclosing casing about said parts, in combination with a jointed air-delivery tube connected with said outlet-pipe, and a burner to heat said hollow member, substantially as described.

4. In a compressed-air-heating apparatus, a hollow air heating and confining member having a circuitous air-passage over its bottom, an inlet and outlet pipe at each end of said passage, a burner beneath said member and an adjustable tube attached to said outlet-pipe, substantially as described.

707,112. MECHANISM FOR CONVERTING MOTION. JAMES HORROCKS, Manchester, England. Filed Jan. 10, 1902. Serial No. 89,148. (No model.)



Claim.—1. The combination of a continuously-rotating shaft, a pinion with teeth of graduated lengths, a reciprocating traverse-block, having internal racks with teeth of graduated lengths, and buffers for minimizing shock and assisting the reversal of the reciprocating motion substantially as and for the purpose set forth and shown.

2. The combination of a reciprocating traverse-block, parallel opposed racks and an intervening driving-pinion, the said racks and pinion having the teeth where they first engage of progressively varying lengths substantially as and for the purpose set forth and shown.

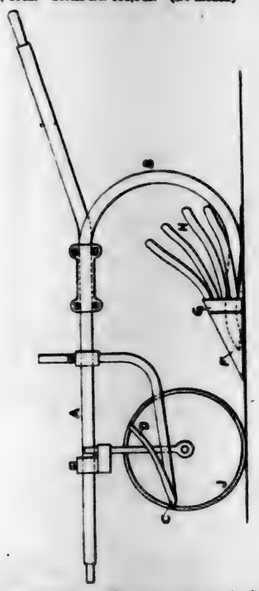
3. The combination with a reciprocating traverse-block, operated by opposed racks, and an intervening continuously-rotating driving-pinion, of buffers rotatable on axes secured on the traverse-block and a buffer rotatable on an axis secured on and revolving with the pinion substantially as and for the purpose set forth and shown.

707,113. CATTLE-FOOD. GEORGE H. HUGHES, London, England. Filed Jan. 31, 1902. Serial No. 91,022. (No specimens.)

Claim.—1. A cattle-food comprising a comparatively dry mixture of the pith of the sugar-cane and molasses.

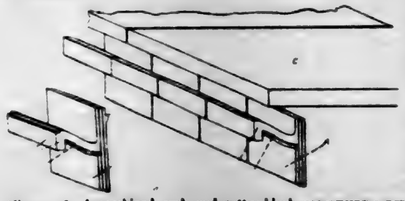
2. A meal for cattle-food comprising a comparatively dry mixture of the pith of the sugar-cane and molasses which is absorbed by the pith.

707,114. POTATO-PLOW. DAVID JACKSON, Tickhill, England. Filed Apr. 1, 1902. Serial No. 101,949. (No model.)



Claim.—The combination, with a plow-beam, and wheels supporting the front part thereof; of a divider having its point arranged centrally under the plow-beam between the said wheels and having two upwardly and rearwardly inclined arms which project in opposite directions, a share secured to the lower and rear part of the plow-beam, and spreading prongs projecting rearwardly from the said share, substantially as set forth.

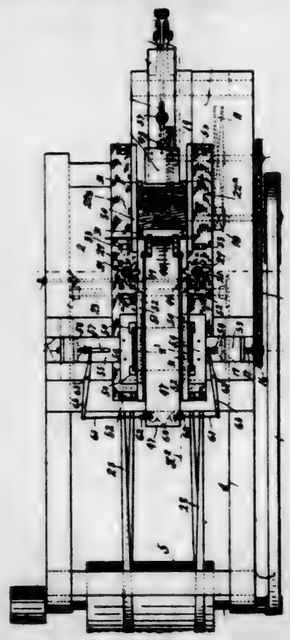
707,115. COMBINED CURB AND GUTTER BLOCK. JOHN R. JECKLIN, Newburgh, N. Y. Filed May 1, 1902. Serial No. 105,627. (No model.)



Claim.—1. A combined curb and gutter block comprising a perpendicular body portion having a flange on the opposite sides of each of the ends of each portion, a horizontally-disposed projection extending outwardly from the center of the face of the body, which projection is slightly conserved on its upper surface and which projection is provided on one end with a lip, and has on the upper and outer edge a longitudinal groove, all substantially as described and shown.

2. A combined curb and gutter block comprising a perpendicular body portion having a flange on the opposite sides of each of the ends of each portion, and having a longitudinal lip at the back and near the top, a horizontally-disposed projection extending outwardly from the center of the face of the body portion, which projection is slightly conserved on its upper surface and which projection is provided on one end with a lip, and has on the upper and outer edge a groove, all substantially as described and shown.

707,116. MACHINE FOR SECURING TOGETHER BOARDS BY MEANS OF CLEATS. CHARLES JOHNSON, Minneapolis, Minn., assignor of one-half to Arthur B. Rogers, Minneapolis, Minn. Filed Apr. 15, 1902. Serial No. 102,972. (No model.)



Claim.—1. The combination with a pair of groove-cutters, of means for feeding the blanks edgewise between said cutters to groove the opposite edges thereof, and a pair of pressing devices for pressing the cleats into the opposite grooved edges of said blank, which pressing devices react the one against the other, substantially as described.

2. The combination with means for feeding the grooved blanks, of means for supplying cleats to the opposite grooved edges of said blanks, and a pair of pressing devices for pressing into said grooved edges of the blanks, which pressing devices react the one against the other, substantially as described.

3. The combination with a pair of laterally-spaced magazines for the cleats, of means for feeding the grooved blanks between said magazines, and reversely-reciprocating feed plungers or blades coöperating with said magazines and serving to press said cleats into the grooves of said blanks, substantially as described.

4. The combination with a pair of laterally-spaced magazines for the cleats, of means for feeding the grooved blanks between said magazines, a pair of reversely-movable cleat-feeding plungers or blades, and means for simultaneously moving said plungers inward, involving a counter-shaft and a pair of cams, carried thereby, substantially as described.

5. The combination with a pair of laterally-spaced magazines for the cleats, one of which magazines is adjustable laterally with respect to the other, of means for supplying the grooved blanks between said adjustable magazines, and reversely-movable cleat-feeding plungers or blades coöperating with said magazines and serving to press the cleats into the grooves of said blanks, substantially as described.

6. The combination with a laterally-adjustable magazine for the blanks, of means for feeding said blanks, one at a time, from said mag-

axine, and a pair of laterally-spaced cleat-supplying magazines between which said blanks are fed, and reciprocating blades or plungers for pressing the cleats into the grooved edges of said blanks, substantially as described.

7. The combination with a magazine for the blanks, and means for feeding the blanks, one at a time, from the magazine, a cutter for grooving an edge of said blank as the same is fed from the magazine, and a cleat-supplying magazine past which the grooved edge of said blank is moved, and means for pressing the cleats from said magazine into the grooved edges of said blank, substantially as described.

8. The combination with a blank-supplying mechanism, and means for feeding the blanks therefrom, one at a time, of a pair of saws or cutters between which said blanks are fed edgewise of a pair of cleat-supplying magazines between which said blanks are fed, after passing said cutters, and means for pressing said cleats into the opposite grooved edges of said blanks, substantially as described.

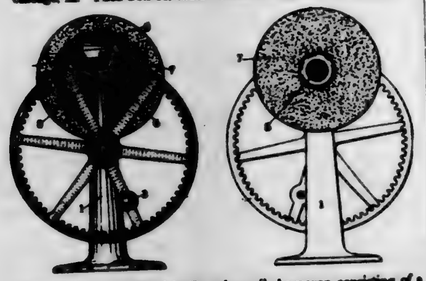
9. The combination with a blank-supplying magazine and a reciprocating blank-feeding plunger or blade, of a pair of saws or cutters for grooving the edges of the blanks as they are fed from the magazine, a pair of laterally-spaced cleat-supplying magazines between which the grooved blanks are fed, and a pair of reversely-reciprocating plungers or blades for simultaneously pressing the cleats into the opposite edges of the blanks, substantially as described.

10. The combination with a blank-supplying magazine and means for feeding the blanks therefrom, one at a time, of a pair of laterally-spaced magazines for the cleats, means for pressing the cleats into the grooves of said blanks, and a pivoted gravity-held presser-board extending from said blank-supplying magazine between said cleat-magazines, and under which the blanks are caused to pass, substantially as described.

11. The combination with a pair of supports extending in the general direction of the feed of the machine, one of said supports being adjustable laterally with respect to the other, of an adjustable blank-supplying magazine, the sides of which are mounted one on each of said supports, means for feeding the blanks, one at a time, from said magazine, a pair of laterally-spaced cleat-magazines mounted one on each of said supports, and means for pressing the cleats from said cleat-magazines into the grooved edges of the blanks, substantially as described.

707,117. WITHDRAWN.

707,118. KNIFE AND PENCIL SHARPENER. LEMUEL JOHNSON, Chicago, Ill. Filed Dec. 18, 1901. Serial No. 86,301. (No model.)

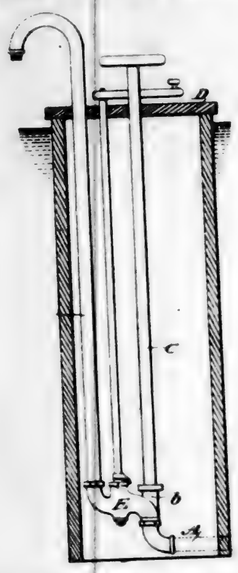


Claim.—1. A combined knife and pencil sharpener, consisting of a journal-box, a revolvable shaft, a rotary cutter and a grindstone mounted on the shaft which latter is mounted in the journal-box, a hollow pencil-holder, a longitudinal opening into the hollow portion of said holder, a boss attached to said holder and the said boss attached to the journal-box, and so disposed that the longitudinal opening in the pencil-holder is close to the rotary cutter, substantially as and for the purpose stated.

2. A combined knife and pencil sharpener consisting of a journal-box having a portion thereof exteriorly screw-threaded, a revolvable shaft, a rotary cutter and a grindstone, the cutter and grindstone mounted on the shaft and the latter mounted in the journal-box, a hollow pencil-holder, a longitudinal opening into one side of said holder and exposing the hollow portion thereof, a hollow boss interiorly screw-threaded and attached to the holder, said boss mounted on the screw-threaded portion of the journal-box with the longitudinal opening in the holder close to the rotary cutter, and means for revolving the shaft, substantially as stated.

3. In a combined knife and pencil sharpener, a supporting-post having a journal-box mounted thereon, a revolvable shaft mounted in the journal-box, a grindstone and a rotary cutter mounted on one end of the shaft and a pinion cog-wheel mounted on the other end thereof, a pin mounted on the supporting-post, an internal cog-wheel revolubly mounted on the pin and in engagement with the pinion cog-wheel, a hollow pencil-holder, one side of said holder having a longitudinal opening, said holder attached to the journal-box with said opening close to the rotary cutter, and means for revolving the internal cog-wheel substantially as and for the purpose stated.

707,119. HYDRANT-COCK. JOHAN H. KIDDER, Pueblo, Colo. Filed Dec. 27, 1900. Serial No. 41,297. (No model.)



Claim.—The double-elbow hydrant-cock herein described, provided with the shoulder *b* combined with the key provided with the slot *a* and the ribs *c c*, as set forth.

707,120. CAR-WHEEL. GEORGE KILLIAN, Scranton, Pa. Filed Aug. 30, 1901. Serial No. 73,893. (No model.)

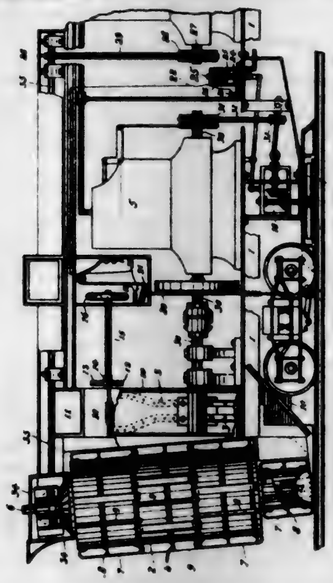
Claim.—1. A car-wheel, comprised of two separate body-disks, the inner one being smaller in diameter than the outer one, a tire provided with an inward-extending flange clamped between the adjacent edges of said plates or disks, said plates or disks being grooved for the reception of said flange, and said tire bearing upon the peripheries of said disks and having the portion bearing on the inner disk thicker than the portion bearing on the outer disk, for the purposes set forth.

2. A car-wheel, consisting of a pair of separate disks, one being smaller in diameter than the other, and a tire bearing upon and covering the peripheries of said disks and provided with an inward-extending flange having lateral subflanges, the inner subflange being nearer the center of the wheel and the inner part of the tire bearing on the inner disk being thicker than the outer part of the tire, for the purposes set forth.

3. A car-wheel consisting of a pair of separate body-disks the inner one being smaller in diameter than the outer one, and a tire bearing upon and covering the peripheries of said disks, the portion of the tire bearing on the inner body-disk being as much thicker than the part bearing on the outer disk as the outer disk is greater in diameter than the inner disk, and means for attaching said tire to said plates.

707,121. CYLINDER ROTARY SNOW-PLOW. HENRY H. KRYGER, Minneapolis, Minn. Filed May 3, 1897. Serial No. 634,973. (No model.)

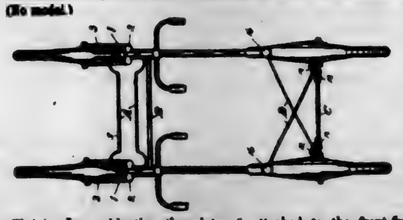
Claim.—1. In a snow-plow, the combination of the forwardly-inclined twin cylinders, rotating in opposite directions upon forwardly-inclined shafts operated by covered or inclosed gearing; open knives, affixed upon the said twin cylinders, adapted to cut the snow parallel therewith; other knives or saw-teeth affixed to, and extending laterally from the said cylinders, adapted to cut the snow at an angle to the said open knives; carriers, affixed to and rotatable with the said twin cylinders adapted to carry the disintegrated snow from opposite directions inward and between them, and a partially-inclosed fan, revolving in the rear of the said twin cylinders; adapted to dissipate the disintegrated snow, and to force it outward through chutes in its case, to either side of the truck, substantially as shown and described.



2. The combination in a snow-plow having revolving cylinders adapted to cut a path or passage therefor, and a revolving fan adapted to dissipate the disintegrated snow; of the automatically-controlled revolving flanger, substantially as shown and described.

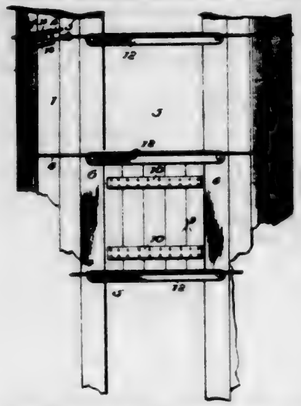
3. In a snow-plow having a suitable frame or support, the revolving twin cylinders 2 rotating in opposite directions, said cylinders being armed with the open knives 7 adapted to cut the snow parallel therewith, with the laterally-revolving saws 8 adapted to cut the snow horizontally; and with the revolving carriers 9 adapted to carry the disintegrated snow from opposite directions between them; said cylinders being rotated by means of shafts, and gears, said shafts and gears being inclosed or inclosed to shield them from the snow, substantially as shown and described.

707,122. DEVICE FOR COUPLING TWO BICYCLES. JOHN KYNASTON, Liverpool, England. Filed Mar. 20, 1902. Serial No. 99,171. (No model.)



Claim.—In combination the plates 1 attached to the front-fork crowns, the guide-rods 5 forming with said plates a parallel steering movement, the yoke B hinged to brackets 6 clipped on the handle-bar stems, the strut C socketed in foot-steps on the rear axles, and the stays D hooked in eye-washers on the rear axles and attached by the tightening bolts and nuts 18, 20, to the clips 17 attached to the seat-pillars 16, forming a coupling for two bicycles, as described.

707,123. SILO. ELMER B. LACEY and ARTHUR J. FULLER, West Auburn, Pa. Filed May 15, 1902. Serial No. 107,503. (No model.)



Claim.—A silo provided with a doorway and with jambs rabbeted to receive the door, in combination with a door consisting of a series of sections, division-strips extending horizontally across the door-opening and curved to conform to the curvature of the silo-walls, keeper-strips of greater width than the division-strips having their ends bolted to the door-jambs, and extending along the outer surface of the division-strips, and a series of door-sections curved to conform to the curvature of the silo-walls and adapted to fit flush between the door-jambs and division-strips, the said door-sections being separately and independently removable and adapted to be held in place by internal pressure, substantially as described.

707,124. BUTT-LOADING FOR WHIPS. HENRY W. LARSON, Springfield, Mass., assignor to Larson Whip Company, Springfield, Mass., a Corporation of Massachusetts. Filed Sept. 5, 1901. Serial No. 74,367. (No model.)

Claim.—1. In a whip or kindred device, the combination of a main portion; a surrounding annular portion whose larger free end extends toward the butt and a metal portion surrounding the main portion below said annular portion and having the latter portion embedded in it.

2. In a whip or kindred device, the combination of a main portion; a surrounding annular convolute covering of textile material, whose free end extends toward the butt, and a metal portion surrounding the main portion below said annular portion and having the latter portion embedded in it.

3. In a whip or kindred device, the combination of a main portion; a substantially funnel-shaped portion whose larger free end extends toward the butt, and a metal portion surrounding the main portion below said funnel-shaped portion and having the latter portion embedded in it.

4. In a whip or kindred device, the combination of a main portion; a substantially funnel-shaped portion whose larger free end extends toward the butt and whose walls taper toward the butt-end, and a metal

portion surrounding the main portion below said funnel-shaped portion and having the latter portion embedded in it.

5. In a whip or kindred device, the combination of a main portion; a substantially funnel-shaped convolute tunible portion whose larger free end extends toward the butt, and a metal portion surrounding the main portion below said funnel-shaped portion and having the latter portion embedded in it.

6. In a whip or kindred device, the combination of a stock having a wrapping of fabric thereon a short distance from the butt-end that tapers upwardly, and a casing of metal molded onto the stock and inclosing the butt-end and also the lower portion of the wrapping.

7. In a whip or kindred device, the combination of a stock; a covering that has an annular portion whose larger free end extends toward the butt and also an intermediate portion; and a metal portion surrounding the stock below said covering and having the annular portion embedded in it and also inclosing said intermediate portion.

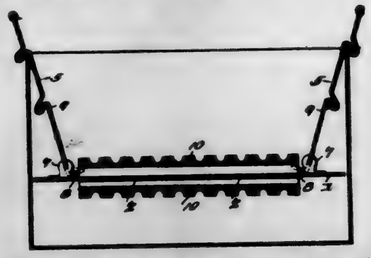
8. In a whip or kindred device, the combination of a stock; a convolute tunible covering that has a substantially funnel-shaped portion whose larger free end extends toward the butt, and whose walls diminish in thickness from an intermediate part toward each end; and a metal portion surrounding the stock below the covering and having the funnel-shaped portion embedded in it.

9. In a whip or kindred device, the combination of a main portion; a substantially funnel-shaped portion whose larger free end extends toward the butt, a metal portion surrounding the main portion below said funnel-shaped portion and having the latter portion embedded in it, and a non-metallic elastic portion located between the upper part of the metal portion and the stock.

707,125. TILE. FREDERICK R. LAWRENCE, Brooklyn, N. Y. Filed Feb. 4, 1902. Serial No. 92,542. (No model.)

Claim.—A tile provided with recesses in its under surface and around the margins thereof, the floors or bottoms of said recesses being inclined or sloping so that the recesses are deeper at their outer ends than at their inner ends, and the side walls of said recesses being inclined together so that the recesses are wider at their inner ends than at their outer ends.

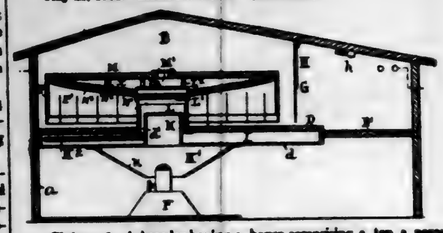
707,126. WASHBOILER. GEORGE LEHMER, Lake City, Minn. Filed Feb. 17, 1902. Serial No. 94,548. (No model.)



Claim.—1. A washboiler attachment comprising a plate conforming to the interior of the boiler and having parallel rows of elliptical perforations arranged longitudinally, said plate being provided with perforated washboiler guard-strips secured longitudinally to cover the rows of perforations therein, said guard-strips being disposed alternately on the upper and under sides of said plate and serving to brace the same longitudinally, and part of said guard-strips being disposed on the under side of said plate to form supports for the latter, substantially as set forth.

2. A washboiler attachment having means at the ends thereof whereby it may be elevated and suspended at various points of elevation, said plate being provided with longitudinally-disposed rows of perforations and with longitudinally-disposed guard-strips covering said perforations and serving also as braces to prevent the plate from flexing or yielding under the weight of the clothes disposed thereon, substantially as set forth.

707,127. BROODER. OTIS B. LITTELL, Fall River, Mass. Filed July 23, 1901. Serial No. 69,711. (No model.)



Claim.—1. A brooder having a hover comprising a top, a porous padding suspended below said top, and means for causing warm air to pass down through said padding.

2. A brooder having a hover comprising a top, a porous padding suspended below said top, means for supplying warm air above said padding and an impervious central portion for directing the warm air to the outer portions of said padding.

3. A brooder having a hover provided with padding and a tubular standard connecting with the space above the padding and forming the sole support for said hover, and means for furnishing warm air to said standard.

4. A brooder having a hover provided with padding, a tubular standard forming the sole support for said hover and made in telescopic sections and connecting with the space above the padding, means for adjustably uniting said sections and means for conveying warm air into said standard.

5. A brooder having a hover comprising a top provided with a double valance one being shorter than the other.

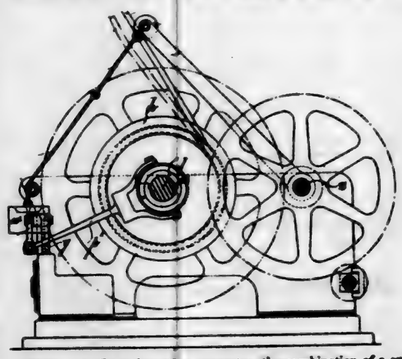
6. A brooder having a hover comprising a top provided with a double valance slit vertically at intervals.

7. A brooder having a hover provided with a padding composed of wire-matting, cotton-batting and a flannel cover.

8. A brooder having a double floor, a hover having a hollow top communicating therewith, and a heater having flues running through the double floor.

9. A brooder having a hinged roof carrying a depending curtain dividing the space into two compartments, a double floor for one of said compartments, a hover in said compartment communicating with the space between said double floors, and means for heating said space.

707,128. ROCK-CUTTING APPARATUS. FRED LOBNITZ, Renfrew, Scotland. Filed Apr. 2, 1902. Serial No. 101,060. (No model.)



Claim.—1. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, winding means connecting the cutter with the winch-drum, a clutch in connection with the drum, and means set in operation by the winding means for applying the clutch.

2. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, winding means connecting the cutter with the winch-drum, a clutch in connection with the drum, and means set in operation by the winding means for automatically applying the clutch.

3. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, and means set in operation by the rope for applying the clutch.

4. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a coil-clutch in connection with the drum, a rope connecting the cutter with the drum, and means set in operation by the rope for applying the coil-clutch.

5. In rock-cutting apparatus, the combination of a cutter, a winch with winch-shaft, a drum loosely mounted on the shaft, a coil-clutch for clutching the drum to the shaft, a hoisting-rope connecting the cutter with the drum, and means set in operation by the rope for applying the clutch, substantially as set forth.

6. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, means for operating the clutch, and means set in operation by the rope for actuating said clutch-operating means, substantially as set forth.

7. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, and means set in operation by the rope for actuating said lever, substantially as set forth.

8. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with said lever, and means set in operation by the rope for operating said rod, substantially as set forth.

9. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with the lever, a collar on the rod, a bell-crank lever capable of striking against said collar and operating said rod, and means for operating the bell-crank lever, substantially as set forth.

10. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with the lever, a collar on the rod, a bell-crank lever capable of striking against said collar and operating said rod, a weight on the bell-crank, and means connecting said weight with the hoisting-rope, substantially as set forth.

11. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with the lever, a collar on the rod, a bell-crank lever capable of striking against said collar and operating said rod, a weight on the bell-crank, a rope attached to said weight, and a roller secured to said rope and which runs upon the hoisting-rope, substantially as set forth.

12. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with the lever, a collar on the rod, a bell-crank lever capable of striking against said collar and operating said rod, a weight on the bell-crank, a rope attached to said weight, a roller secured to said rope and means for supporting the roller so that it may rest upon the hoisting-rope, substantially as set forth.

13. In rock-cutting apparatus, the combination of a cutter, a winch with winding-drum, a clutch in connection with the drum, a rope connecting the cutter with the drum, a lever for operating the clutch, a rod connected with the lever, a collar on the rod, a bell-crank lever capable of striking against said collar and operating said rod, a weight on the bell-crank, a rope attached to said weight, a roller secured to said rope, and an arm movably secured to the winch for supporting the roller so that it may rest upon the hoisting-rope, substantially as set forth.

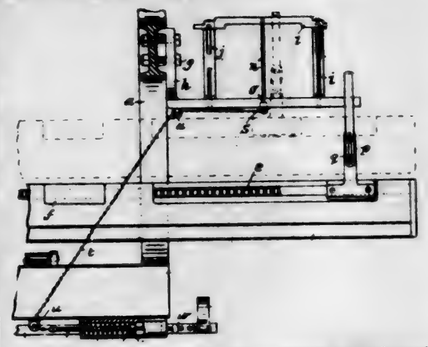
707,129. COMPOSITION FOR MAKING STONES OR MORTAR. JEAN LOEWENTHAL, Magdeburg, Germany, assignor to the Ceramital Company, New York, N. Y. Filed May 23, 1902. Serial No. 108,726. (No specimens.)

Claim.—1. The herein-described composition of matter consisting of clean quartz sand, pulverized quartz, alumin, magnesia, borax, graphite, mineral oil, poor in carbureted hydrogen, and water, substantially as described and for the purpose specified.

2. The herein-described composition of matter consisting of clean quartz sand eighty-five pounds, pulverized quartz four pounds, alumin one-half pound, magnesia one pound, borax two pounds, graphite one-half pound, mineral colors two pounds, mineral oil poor in carbureted hydrogen one-half gallon, and water one-fourth gallon, substantially as described.

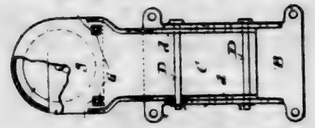
707,130. STOPPING DEVICE FOR LOOMS. WILLIAM T. LOUIS, Easton, Pa. Filed Apr. 21, 1902. Serial No. 103,962. (No model.)

Claim.—1. In a stop-motion mechanism for narrow-ware looms, the combination, with the batten, of a reciprocating part on the batten movable transversely of the movement thereof, a spring-pressed part adapted to actuate the power-controlling mechanism of the loom, a stationary part having an opening, a plug adapted to be received by said opening, operative connecting means between the plug and said spring-pressed part, and means, controlled by said reciprocating part, for forcing said plug from the opening, substantially as described.



2. In a stop-motion mechanism for narrow-ware looms, the combination, with the batten, of a reciprocating part on the batten movable transversely of the movement thereof, a spring-pressed part adapted to actuate the power-controlling mechanism of the loom, a stationary part having an opening, a plug adapted to be received by said opening, operative connecting means between the plug and said spring-pressed part, and means, comprising coactive members carried the one by said reciprocating part and the other by said arm, for forcing said plug from the opening, substantially as described.

707,131. DOOR-HANGER. PETER H. LUTTIN, Milwaukee, Wis., assignor to Luttin and Sons Manufacturing Company, Milwaukee, Wis. Filed Apr. 16, 1902. Serial No. 103,499. (No model.)



Claim.—A sliding-door hanger comprising two sheet-metal sections adjustable longitudinally one upon the other and each provided with integral outer vertical flanges perforated at intervals of their length, the flanges of one section being movable along those of the other section, bolts engaging registering perforations in all the flanges, means for preventing automatic displacement of the bolts, and a track-roller carried by one of the sections aforesaid.

707,132. CENTRIFUGAL LIQUID-SEPARATOR. WILBUR W MANNY, Waterloo, Iowa, assignor to Hackett & Dailey Creamery Supply Company, Waterloo, Iowa. Filed Dec. 5, 1901. Serial No. 84,736. (No model.)

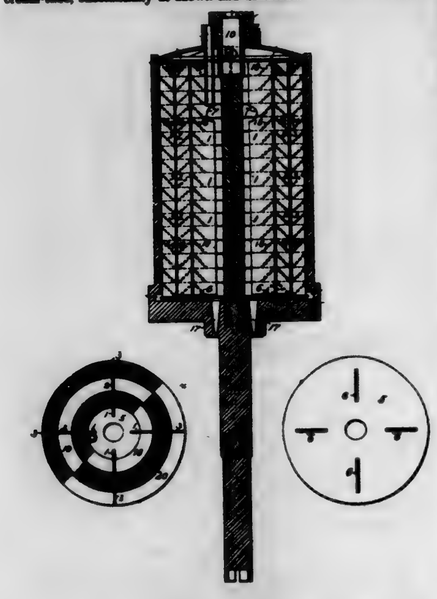
Claim.—1. A liner for centrifugal liquid-separators, formed of separable parts arranged concentrically about and spaced from each other each part being composed of a series of superimposed annular imperforate plates and uprights with which all the plates in a series are rigidly connected, a bowl, and top and bottom plates therein independently connected to certain of said uprights.

2. A liner for centrifugal liquid-separators, formed of separable parts arranged concentrically about and spaced from each other, each part being composed of a series of superimposed annular imperforate plates and uprights with which all the plates in a series are rigidly connected, a bowl, and top and bottom plates therein independently connected to the outermost and innermost uprights, while the intermediate uprights are unattached to either part.

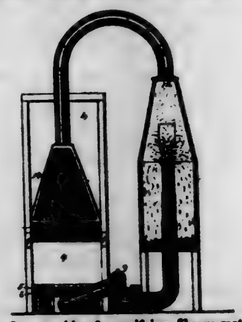
3. A liner for centrifugal liquid-separators, formed of separable parts arranged concentrically about and spaced from each other, each part being composed of a series of superimposed annular imperforate parts formed in the shape of truncated cones, the plates of one series inclined at an angle to the plates of the series adjacent, uprights along the edges of the plates in each series, and means for supporting said uprights.

4. A liner for centrifugal liquid-separators, formed of separable parts

arranged concentrically about and spaced from each other, each part being composed of a series of superimposed annular plates connected rigidly together by uprights, the outer series attached to a perforated bottom plate and the inner series attached to a perforated top plate containing a cream-tube, substantially as shown and described.



707,183. MACHINE FOR CIRCULATING AND SEPARATING WASTE FIBROUS MATERIALS. JAMES MARSHALL, Fall River, Mass. Filed Feb. 12, 1902. Serial No. 93,770. (No model.)



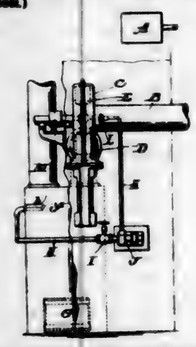
Claim.—1. In a machine for purifying fibrous materials, the combination therewith of an auxiliary system continuously circulating the waste or droppings therefrom, consisting of a receiving-pan into which said droppings fall, an exhaust-fan emptying said pan, a separating-chamber into which said pan delivers its exhaust, and a pipe leading the purified products from said separating-chamber back to the original machine, substantially as described and shown.

2. In an auxiliary machine for separating the waste made from purifying fibrous materials the combination with the outlet through which the waste products of the original machine are discharged, of a receptacle into which they fall, an exhaust-fan connected to said receptacle removing and conveying said waste forward, a separating-chamber adjoining, into which they are discharged and a return-passage from said chamber to the original machine substantially as described and shown.

3. In a machine for separating the waste made by purifying fibrous materials, the combination of an auxiliary separator consisting of a chamber into which the wastes are discharged, an inlet-pipe rising through said chamber to a suitable height for separating purposes, an outlet from said chamber, and means for generating an air-current by which said wastes are delivered into said chamber, purified, and removed from said chamber, substantially as described and shown.

4. In a machine for separating fibrous waste materials, the combination with the outlet through which the waste products of the original machine are discharged, of a receptacle into which they fall a transfer-fan connected therewith, a separating-chamber connected to the fan, a top exit from said chamber connected to a passage terminating in a wire cage erected over the feed-inlet of the original machine, through which passage, the recovered wastes are returned by means of the air-current generated by the fan, to the original machine, substantially as described and shown.

707,184. APPARATUS FOR CLEANING AIR FROM SAND-BLAST APPARATUS. JEREMIAH R. MATHEWSON, Broad Heath, near Manchester, England, assignor, by mesne assignments, to Benjamin C. Tilghman, Jr., and Richard Tilghman, trading as The Firm of B. C. & R. A. Tilghman, Philadelphia, Pa. Filed Sept. 20, 1901. Serial No. 75,742. (No model.)

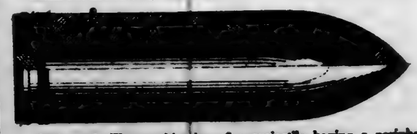


Claim.—1. The combination with a sand-blast plant and an exhaust-conduit pipe leading from said plant and adapted to draw dust-laden air from said locality, of an exhaust-fan coupled to said conduit and a nozzle arranged to throw a jet or jets of water upon the rotating blades of the fan, whereby said water is finely divided and thoroughly mixed with the dust-laden air.

2. The combination with a sand-blast plant and an exhaust-conduit pipe leading from said plant and adapted to draw dust-laden air from said locality, of an exhaust-fan coupled to said conduit, a nozzle arranged to throw a jet or jets of water upon the rotating blades of the fan, whereby said water is finely divided and thoroughly mixed with the dust-laden air, and a receptacle connected with the delivery side of the fan to receive the mud mixed with the air and permit the cleaned air to escape.

3. The combination with a sand-blast plant and an exhaust-conduit pipe leading from said plant and adapted to draw dust-laden air from said locality, of an exhaust-fan coupled to said conduit, a nozzle arranged to throw a jet or jets of water upon the rotating blades of the fan whereby said water is finely divided and thoroughly mixed with the dust-laden air, a water-tank having means for maintaining water at approximately the same level, and a delivery-pipe leading from the fan to a point in the tank above the water-level.

707,185. DEVICE FOR THE PREVENTION OF EROSION IN ORDNANCE. HERMAN MAHIN, New York, N. Y. Filed Nov. 13, 1899. Serial No. 736,927. (No model.)



Claim.—1. The combination of a projectile having a peripheral shoulder and a conical rearwardly-tapering rear portion, a pressure-ring surrounding and capable of longitudinal movement on said rear portion, and an obturating-ring of plastic material between the pressure-ring and said shoulder on the projectile.

2. The combination of a projectile having a peripheral shoulder near its base and a conical rearwardly-tapering rear portion, a pressure-ring surrounding and capable of longitudinal movement on said rear portion, a gas-check ring or seat between said pressure-ring and rear portion and an obturating-ring of plastic material between the pressure-ring and said shoulder on the projectile.

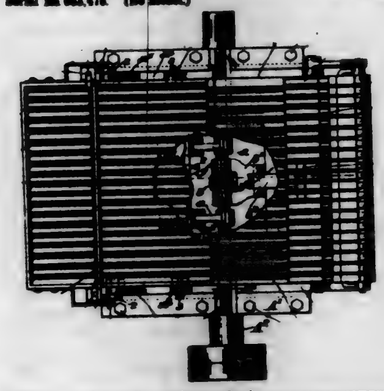
3. The combination of a projectile having a peripheral shoulder and a draw-hook groove formed in an integral portion of the projectile, and also having a conical rearwardly-tapering rear portion with a pressure-ring surrounding and capable of longitudinal movement on said tapering rear portion but leaving said groove exposed, and a plastic obturating-ring between said pressure-ring and the shoulder of the projectile.

4. The combination of a projectile having a reduced rear portion with a draw-hook groove formed therein, a peripheral shoulder on the projectile, a pressure-ring surrounding said reduced rear portion and cut away so as to expose said draw-hook groove and an obturating-ring between said pressure-ring and peripheral shoulder.

5. The combination with a projectile of an obturating-ring composed of fibrous material interwoven with metallic wire or gauze and impregnated with a plastic material.

6. The combination with a projectile of an obturator composed of a plurality of rings of fibrous material interwoven with metallic wire or gauze and impregnated with a plastic material, said rings having laminæ of such metal interposed between them.

707,186. NAIL-ASSORTING MECHANISM. BENJAMIN F. MAYO, Salem, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed June 15, 1896. Serial No. 693,670. (No model.)



Claim.—1. In a nail-assorting mechanism, a raceway composed of a plurality of grooved transversely-arranged plates and means to move them independently simultaneously in opposite directions, substantially as described.

2. In a nail-assorting mechanism, a raceway composed of a plurality of transversely-arranged grooved plates, a shaft, and means connecting said shaft and plates to move them simultaneously independently one of the other in the direction of the length of the grooves therein, substantially as described.

3. A plurality of inclined raceway-plates, grooved to receive and guide nails, one of said plates occupying a position in a lower plane than the other of said plates, and means to impart motion independently to each of said plates but in opposite directions simultaneously, for the purposes set forth.

4. A raceway presenting a plate having a series of wide and deep grooves, and a second plate in continuation of it having a series of narrow grooves with wider spaces at the sides of said grooves, said second plate being located in a plane below the plane of the former plate, whereby the plate having the narrow grooves may always be kept well filled from the plate having the wide and deep grooves, substantially as described.

5. A raceway presenting an inclined plate having a series of wide and deep grooves, and a second plate having a series of narrow grooves with wider spaces at the sides of said grooves, and discharge-openings, said second plate being located in a plane below the plane of the plate having the wide and deep grooves, whereby the plate having the wide and deep grooves may always keep filled the narrow grooves of the second plate, substantially as described.

6. A raceway presenting an inclined plate having a series of wide and deep grooves, and a second plate having a series of narrow grooves with wider spaces at the sides of said grooves and discharge-openings, said second plate being located in a plane below the plane of the plate having the wide and deep grooves, whereby the plate having the wide and deep grooves may always keep filled the narrow grooves of the second plate, and a returning-plate to receive the nails discharged through said opening, substantially as described.

7. In a nail-assorting mechanism, the following instrumentalities, viz: a raceway composed of a plurality of grooved plates arranged transversely of the machine, a shaft, and connections between it and said plates to move them simultaneously in opposite directions, thus shaking them in the direction of the lengths of the grooves therein; a nail-lifter located at the lower end of said raceway, means to actuate it, raceway-terminals, and a suitable controlling device to provide for the delivery in the proper direction as to their heads and points of the nails leaving the terminal, substantially as described.

8. In a nail-assorting mechanism, a raceway-plate, and an inclined returning-plate to receive upon it surplus nails discharged from said raceway-plate; combined with a nail-feeding plate substantially equal in width to said returning-plate and normally occupying an inclined position at the end of said returning-plate to receive upon it nails leaving said returning-plate, a guide for said feeding-plate, and means to lift said feeding-plate vertically from a position at or below the delivery end of the returning-plate into a position at or above the receiving end of the raceway-plate and to tilt said plate, in order that nails coming upon the feeding-plate may be automatically transferred therefrom to said raceway-plate.

9. A nail-assorting mechanism comprising a raceway consisting of a plurality of parts arranged to feed nails and means to move said parts independently, combined with mechanism for receiving nails from said raceway and delivering them all pointing the same way.

10. In a nail-assorting mechanism, the following instrumentalities, viz: a raceway, a returning-plate grooved to receive and guide the nails, combined with a nail-feeding plate having a series of grooves and arranged transversely with relation to said returning-plate, means to move said feeding-plate, it being supported independently of said returning-plate, a suitable transverse space being left between said returning-plate and said feeding-plate for the passage therethrough of nails coming down said returning-plate crosswise of its grooves, substantially as described.

11. A raceway to guide nails presenting a plurality of parts, divided transversely of the direction of travel of the nails, and means to move said parts independently in the direction of the travel of the nails.

12. A raceway consisting of a plurality of parts located at different levels and each having a series of grooves, and means to move said parts independently.

13. A raceway consisting of a plurality of parts, each part having a series of grooves for nails, means to move said parts independently, and means to supply automatically one of said parts with nails to be assorted.

14. A raceway consisting of a plurality of parts, each part having a series of grooves for nails, means to move said parts independently, and a suitable controlling device to provide for the delivery of the nails with their heads and points in the proper directions.

15. In a nail-assorting mechanism, a plurality of oppositely-inclined plates to receive and guide nails, and means for reciprocating said plates simultaneously in opposite directions to cause nails to travel along said plates in the directions of said inclinations.

16. A nail-assorting mechanism comprising a raceway and a returning-table and being divided into a plurality of parts; and means for reciprocating said parts simultaneously in opposite directions to cause the nails to travel on the raceway and returning-table.

17. In a nail-assorting mechanism, a plate to receive and guide nails, a returning-table, and means for reciprocating said plate and table simultaneously in opposite directions to cause the nails to travel thereon.

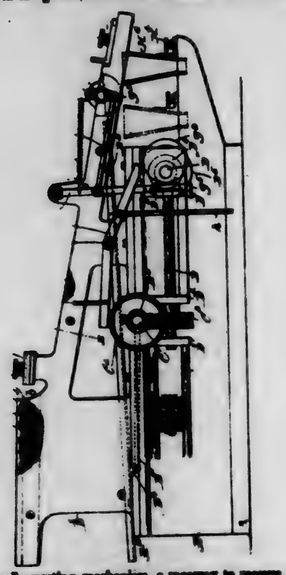
18. In a nail-assorting mechanism, a plate for receiving and guiding nails, said plate having provision for rejecting nails not properly lodged thereon; a second plate for receiving and conveying the rejected nails, and means for reciprocating said plates in opposite directions to cause the nails to travel thereon.

707,187. NAIL-ASSORTING APPARATUS. BENJAMIN F. MAYO, Salem, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed Oct. 26, 1896. Serial No. 609,708. (No model.)

Claim.—1. A grooved raceway having provision to automatically assort the nails entering the upper runs of its grooves head and point first indiscriminately, and put said nails into the lower parts of said grooves all head first, combined with a device to receive the endmost nails, a step to position said nails on said device, a series of pockets to receive and conduct the inserted nails, and means to move said device to deliver the nails coming upon it directly from the raceway into said pockets, substantially as described.

2. A raceway presenting a series of continuous grooves in two levels inclined in the same direction and having a transverse groove between said levels to form a series of shoulders, the upper level receiving nails with their heads and points arranged indiscriminately; and a nail-point receiver crossing the grooves of said lower level whereby those nails which

are head first continue to travel forwardly into the grooves of the lower level of the raceway, the nails with their points leading in the grooves of the higher level crossing said transverse groove until their heads leave said higher level, when said nails are reversed and thereafter continue to travel forwardly in the grooves of the lower level of the raceway.



2. In a nail-inserting mechanism, a raceway to receive and guide nails, means to reciprocate said raceway, a device to transfer nails from said raceway, mechanism for actuating said device to transfer nails, and means for stopping the reciprocations of the raceway while said transferring device is being operated.

4. In a nail-inserting apparatus the following instrumentalities, viz: a raceway, a device located near the lower end thereof to receive the nails from said raceway, an independent step to position the nails on said device, and means to tip the said device to effect the discharge of the nails therefrom, substantially as described.

5. In an apparatus of the class described, a raceway to receive, conduct, and deliver nails head first, a series of pockets to receive said nails, a grooved table located intermediate the delivery end of said raceway and the said pockets to receive all said nails head first, and a step to position the nails thereon, combined with means to tip said table to effect the discharge of its nails into said pockets, substantially as described.

6. A raceway adapted to receive and guide nails, a series of pockets in which the inserted nails are finally to be discharged, combined with a device located intermediate the said raceway and the said pockets to receive said nails, an independent step to position said nails on said device, and means to actuate said device to deliver the nails into said pockets either head first or point first, substantially as described.

7. In an apparatus of the class described, a raceway to receive and conduct nails, a series of adjustable pockets, and a device located between said raceway and adjustable pockets to receive the nails from said raceway, and means adapted to be changed as to position to tip said device in either direction when it is desired to deliver the nails therefrom either head first or point first, substantially as described.

8. In an apparatus of the class described, a step to receive against it the head of a nail after the same has entered a grooved table, a grooved table having journals, a cam, and means intermediate said cam and one of said journals to oscillate said table to effect the discharge of nails therefrom, substantially as described.

9. In an apparatus of the class described, a raceway grooved to conduct nails, said raceway having provision to assort the nails put into said groove with heads and points indiscriminately, so that said nails may follow in a continuation of said groove head first, a grooved table to receive the nails head first, a pocket, a cam, means to actuate it, and means actuated by said cam to tip said table and effect the discharge of the nails therefrom, substantially as described.

10. In a nail-inserting apparatus, the following instrumentalities, viz: a raceway having its surface at different levels and provided with continuous grooves, and having a shoulder to leave a transverse space intermediate the two ends of said grooves, an adjustable nail-point receiver located near the said shoulder and below the said transverse space, combined with a device to receive the nails asserted on said raceway head first, and a step to position the said asserted nails on said device, and means to actuate said device to discharge the nails therefrom, substantially as described.

11. In a nail-inserting apparatus, the following instrumentalities, viz: a raceway to receive and guide a series of nails, a rotating shaft having a clutch adapted when in operative engagement therewith to effect the reciprocations of said raceway, a device to receive a series of nails from said raceway, a second shaft having a clutch, means intermediate said second shaft and the device for receiving said series of nails to effect the discharge of said series of nails from said device when the latter clutch is engaged, and means whereby when one of said clutches is in its operative position to rotate one of said shafts, the other of said clutches will be disengaged to leave at rest the shaft with which it cooperates, substantially as described.

12. A raceway to conduct nails, a tipping table to receive nails from said raceway, an independent step for the ends of the nails leaving said raceway and coming onto said table, combined with a series of pockets, and means to tip the said table and cause one edge thereof to pass below the level of the delivery end of said raceway in order that the nails on said table may slide therefrom into said pockets, substantially as described.

13. A raceway to receive and guide a series of nails, a device arranged at the lower end thereof and provided with a double set of nail-receiving grooves, one being wider than the other, the narrower of said grooves receiving nails from said raceway which are to be utilized, a step to position said nails on said device in its narrower grooves, an overflow-pan, a series of pockets, and means to actuate said device whereby the nails left in the broader grooves enter the overflow-pan, the nails which lie in the narrower grooves entering said pockets, substantially as described.

14. In a nail-inserting apparatus, the following instrumentalities, viz: a raceway to receive and guide a series of nails, a rotating shaft having a clutch and adapted to effect the reciprocations of said raceway when said clutch is in engagement with said shaft, a device to receive the nails from said raceway, means to actuate said device and means to arrest the reciprocations of said raceway while the said device is being actuated to discharge from it the nails thereon, substantially as described.

15. A raceway adapted to receive and guide nails, means to reciprocate said raceway, a device to receive nails from said raceway, means to actuate said device to deliver nails, and means to stop the reciprocation of the raceway during the delivery of nails, substantially as described.

16. A raceway adapted to receive and convey nails, means to cause the nails all to point the same way on said raceway, a device to transfer the nails from said raceway, and means to operate said device whereby the nails may be delivered therefrom either head first or point first, substantially as described.

17. A raceway composed of a grooved plate having its surface in two different levels to thereby constitute an upper and a lower section, said raceway having a transverse groove or space to leave a shoulder, said sections having nail-conducting grooves in line, the said grooves being deepest at said shoulder, combined with a nail-point receiver crossing the lower section of said raceway above the grooves and below said shoulder, to operate, substantially as described.

18. In a nail-inserting mechanism, an inclined raceway to receive and guide nails, means to reciprocate the raceway and cause the nails to descend, and means for intermittently stopping the reciprocation of the raceway to arrest the forward movement of the nails.

19. In a nail-inserting mechanism, a raceway to receive and guide nails, means to reciprocate said raceway, a device to transfer nails from said raceway, mechanism to actuate said device to transfer nails, and means controlling said reciprocating means and said actuating mechanism whereby one is made inoperative when the other is operative.

20. In a nail-inserting mechanism, a raceway to receive and guide nails with their heads and points arranged indiscriminately, means to cause said nails all to point the same way on said raceway, a device to transfer the nails from said raceway, and means to actuate said transferring device to deliver nails.

21. In a nail-inserting mechanism, a nail-controller grooved to receive nails, and means to actuate said controller whereby it may be made to deliver the nails from its grooves either head first or point first.

22. In a nail-inserting mechanism, means to guide and direct a series of nails, a device to receive said series of nails therefrom at one operation, and means to actuate said device whereby it may be made to deliver the nails either head first or point first as may be desired.

23. In a nail-inserting mechanism a raceway, a device to transfer nails from the raceway, means to reciprocate the raceway, and means for intermittently stopping the reciprocation of the raceway while the transferring device operates.

24. In a nail-inserting mechanism, a raceway presenting nail-guiding grooves arranged at different levels, the upper level of the raceway receiving nails with their heads and points arranged indiscriminately, means between said levels to reverse some of the nails to insure that all the nails on the lower level of the raceway may have their heads all in the same direction, means to reciprocate said raceway, to cause the nails to travel thereon, and a device under the control of the operator to emit a stroke of the raceway leaving the raceway at rest temporarily when it is desired to stop the movement of the nails on the raceway.

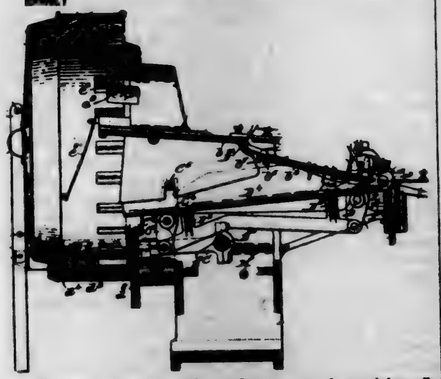
25. In a nail-inserting mechanism, a raceway presenting nail-guiding grooves arranged at different levels, the upper level of the raceway receiving nails with their heads and points arranged indiscriminately, means between said levels to reverse some of the nails to insure that all the nails on the lower level of the raceway may have their heads all in the same direction, means to reciprocate said raceway, and a device under the control of the operator to emit a stroke of the raceway to leave the raceway at rest temporarily, and means for moving said device to start again the reciprocations of said raceway.

26. In a nail-inserting mechanism, a raceway to receive nails with their heads and points arranged indiscriminately and having provision to arrange all said nails during their travel along said raceway with their heads in the same direction, means to reciprocate said raceway to cause the travel of nails thereon, a device located at the end of said raceway to receive and sustain a series of nails delivered from the raceway, and means to stop the reciprocations of said raceway while the series of nails is discharged from said device.

27. In a nail-inserting mechanism, a raceway having an inclined receiving-section to receive and guide nails with their heads and points arranged indiscriminately and having a secondary section at a greater inclination, means for causing the nails to travel on said raceway, and means for causing the nails delivered from the receiving-section to point all in the same direction on the secondary section.

28. In a nail-inserting mechanism, an inclined raceway to receive and guide nails, means for causing the nails to move down said raceway, means for causing said nails all to point the same way on said raceway, a device to transfer the nails from said raceway, and means to actuate said transferring device.

707,188. NAIL-ASSORTING MECHANISM. BENJAMIN F. MAYO, Salem, and ALVIN D. ELLIOTT, Winchester, Mass., assignors to United Shoe Machinery Company, Paterson, N. J., and Boston, Mass., a Corporation of New Jersey. Filed Apr. 26, 1902. Serial No. 104,373. (No model.)



Claim.—1. In a nail-inserting mechanism, means for supplying nails, mechanism for delivering nails, a raceway to receive nails from the supplying means and guide them to the delivering mechanism, a reversing-table, and means for reciprocating said raceway and table simultaneously in opposite directions to cause the nails to travel thereon.

2. In a nail-inserting mechanism, means for supplying nails, mechanism for delivering nails, a raceway for receiving nails from the supplying means and guiding them to the delivering mechanism, said raceway having provision for rejecting nails not properly lodged thereon; a second raceway for receiving and conveying the rejected nails; and means for reciprocating said raceways in opposite directions, to cause the nails to travel on said raceways.

3. In a nail-inserting mechanism, a raceway having grooves to receive and guide nails, mechanism for depositing nails upon said raceway, and a bridge interposed between said mechanism and the raceway to assist in distributing the nails uniformly upon the raceway, said bridge having a plurality of open spaces for the passage of the nails.

4. In a machine of the class described, a rotary magazine containing at one end a series of nail-lifting shelves and at the other end a series of obliquely-arranged blades to guide the nails toward the end of the magazine having the shelves.

5. In a machine of the class described, a magazine, and a frame to hold said magazine in operative position, said frame being also adapted to be tipped into position to sustain said magazine on its side so that it may be supplied with nails.

6. In a machine of the class described, a chute comprising a bar provided with a series of nail-passages, a second bar closing the open sides of said passages, and a series of tubes sustained by said bars in line with the nail-passages.

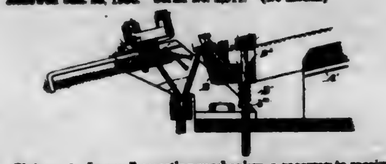
7. In a nail-inserting mechanism, a raceway comprising an upper section to receive nails with their heads and points arranged indiscriminately, a section arranged at a lower level to receive the nails from said upper section, and a nail-reverser located adjacent to the contiguous ends of said sections, and having grooves to receive the ends of the point-first nails and permit them to travel until their heads are unsupported, said grooves being extended and deflected to receive slivers or imperfect nails and discharge them from the lower end thereof.

8. In a machine of the class described, a raceway to receive and guide nails, means to reciprocate the raceway to cause the nails to travel thereon, mechanism for delivering a series of nails from the raceway, means to detain positively the series of nails next to the series being delivered, and means to suspend the reciprocations of the raceway while the detaining means is operative.

9. In a machine of the class described, a raceway for receiving and guiding nails, said raceway having provision for rejecting nails not properly lodged thereon, a returning-table for receiving and conveying the rejected nails, and a rotary magazine for supplying nails in built to the raceway and having an opening in one side to permit the return of nails to the magazine by the returning-table.

10. In a nail-inserting mechanism, a raceway to receive and guide nails, a device to discharge nails from the raceway, reversing means for causing the nails so discharged to point in the opposite direction, and mechanism for imparting to said reversing means a reciprocating movement to facilitate the delivery of nails therefrom.

707,189. NAIL-ASSORTING MECHANISM. BENJAMIN F. MAYO, Salem, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed Feb. 25, 1898. Renewed Jan. 28, 1902. Serial No. 93,011. (No model.)



Claim.—1. In a nail-inserting mechanism, a raceway to receive and guide nails, a device to reverse the nails traveling point first on said raceway, and means to prevent said device from acting on the nails traveling head first on said raceway.

2. In a nail-inserting mechanism, a raceway to receive and guide nails, means to present an abutment to stop nails traveling head first on the said raceway and allow them to drop, and means to withdraw said abutment and allow the nails traveling point first to continue their forward movement.

3. In a nail-inserting mechanism, a raceway to receive and guide nails, a device to transfer nails from said raceway, means to actuate said device to stop the nails coming head first on said raceway and allow them to drop, and means to actuate said device to allow the nails coming point first to continue their forward movement.

4. A raceway-terminal, a nail-arrester located a short distance therefrom and adapted to receive against it the point and one side of a nail next said point, and means to move said arrester away from said terminal to enable the heads of the nails yet supported on the raceway to leave said raceway, the arrester detaining the points of the nails until the heads have fallen sufficiently far to lead in the further movement of the nails.

5. In a nail-inserting mechanism, a plurality of raceways, and a raceway-section provided with a plurality of grooves to receive nails with their heads and points arranged indiscriminately, a series of nail-pockets, and a nail-arrester to receive against it and arrest only the nails leaving said section point first, said arrester being adapted to be moved to effect the discharge of the arrested nails head first into the pockets, substantially as described.

6. A series of pockets to receive nails, a nail plate or gage having a series of grooves one for each of said pockets; combined with a nail-

arrester located between said gage and pockets and composed of two parts, one part movable on or with relation to the other part, means to move said arrester that one part may be made to underlie the points of the point-first nails prior to the removal of the same from the said gage, substantially as described.

7. A nail-gage having a series of raceways and located near a series of pockets, a raceway for each pocket, combined with a nail-arrester, composed of two parts one part movable on or with relation to the other part in order that one part may be made to underlie the points of the nails, said arrester being thereafter movable as an entirety away from said gage to enable the heads of the nails supported on said gage to leave it and drop head foremost into said pockets, substantially as described.

8. In a machine of the class described, a nail-arrester composed of plates, and means to move one of said plates on or with relation to the other to expose a portion of one of said plates to constitute a stop to receive upon it the under edge of a point of a nail, combined with a nail-gage to support the heads of a series of nails the points of which are sustained by the said arrester, substantially as described.

9. A nail-gage having a series of raceways and located near a series of pockets, a raceway-section for said pockets, combined with a nail-arrester composed of parts one movable on or with relation to the other part in order that one part may be made to underlie the points of said nails, said arrester being thereafter movable as an entirety away from said gage to enable the heads of the nails supported on said gage to leave it and drop head foremost into said pockets, a slide having holes and coöperating with said pockets, and means to move said slide to permit the discharge from said pockets of the nails contained therein, substantially as described.

10. A nail-asserting mechanism comprising raceways to receive and guide nails, suitable receptacles to receive nails having said raceways head first, and a device intermediate said raceways and said receptacles to first support temporarily the points of the nails having said raceways point first and to thereafter support the under sides of said nails near said points that they may be discharged from said raceways head first.

11. In a nail-asserting mechanism raceways to receive and guide nails, means to present an obstument to stop nails traveling head first on the raceways and allow them to drop head first, and means to withdraw said obstument and allow the nails traveling point first on the raceways to continue their forward movement until their heads have left the raceways, said nails then being free to drop head first.

12. In a nail-asserting mechanism raceways to receive and guide nails, means to present an obstument to stop nails traveling head first on the raceways and allow them to drop, means to withdraw said obstument and allow the nails traveling point first to continue their forward movement, suitable receptacles for the nails, and gates in said receptacles arranged first to sustain the nails and then to allow them to leave said receptacles.

707,140. NAIL-ASSORTING APPARATUS. ALVIN D. ELLIOTT, Lawrence, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed June 15, 1901. Serial No. 63,686. (No model.)

Claim.—1. In a nail-asserting apparatus, the following instrumentalities, viz: a terminal to receive a series of nails with their heads and points arranged in grooves therein indiscriminately, a circularly-movable controller having a series of grooves to receive the nails having said terminal head first, a gate to receive against its edge the points of the nails having the terminal point first, and means to actuate said controller to carry said gate away from said terminal to thereby enable the heads of the nails on said terminals to drop therefrom into said grooves head first, substantially as described.

2. In a nail-asserting apparatus, the following instrumentalities, viz: a terminal to receive a series of nails with their heads and points arranged indiscriminately, a controller having a series of grooves into which the nails leaving the terminal head first enter by gravity, a notched gate carried by said controller and standing normally with the unnotched edge of the gate crossing said grooves to receive against it the points of the nails having the terminal point first, and means to move said gate to place its notches in position to be entered by the points of the nails, substantially as described.

3. In a nail-asserting apparatus, the following instrumentalities, viz: a terminal to receive a series of nails with their heads and points arranged indiscriminately, a controller having a series of grooves into which the nails having the terminal head first enter by gravity, a notched gate carried by said controller and standing normally with the unnotched edge of the gate crossing said grooves to receive against it the points of the nails having the terminal point first, and means to move said gate to place its notches in position to be entered by the points of the nails, means to impart a circular movement to said controller, and a chute to receive the nails from said controller, substantially as described.

4. In a nail-asserting apparatus, the following instrumentalities, viz: a circularly-movable controller having grooves to receive a series of nails head first, a chute-mouth having two sets of nail-receiving passages, and actuating means to move said controller, said means containing provisions for moving said controller forwardly or backwardly to discharge said nails therefrom either head first or point first into one or the other of said passages as desired, substantially as described.

5. In a nail-asserting apparatus, a controller having a series of grooves, a notched gate arranged parallel therewith and crossing said grooves, means to impart circular motion to said controller combined with means to move said gate longitudinally on or with relation to said controller to place the notches of the gates alternately in line with and then out of line with relation to said grooves, substantially as described.

6. In a nail-asserting mechanism, means to guide and direct a series of nails with their heads and points arranged indiscriminately, a device to receive said series of nails therefrom at one operation, and means to actuate said device whereby it may be made to deliver said series of nails either head first or point first as may be desired.

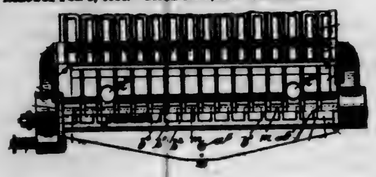
7. In a nail-asserting machine, means to receive and guide nails, a double series of pockets, a nail controller or device located between the means to receive and guide the nails and the receiving ends of said double series of pockets, and means adapted by change of position to move said controller either forward or backward, as may be desired to discharge the nails in the grooves of the controller into said pockets head or point first, substantially as described.

8. In a nail-asserting machine, a lifting device to lift a series of nails having their heads and points arranged indiscriminately, a grooved terminal to receive and guide the nails deposited thereon from said lifting device, a circularly-movable nail controller or device having grooves some of which receive nails which leave the terminal head first, and means to stop temporarily the nails leaving said terminal point first, and means to thereafter enable said nails to move somewhat longitudinally in order that their heads may be removed from the said terminals and dropped head first into the unoccupied grooves of said device, a plurality of series of pockets, and means to turn said device in one or the other direction as may be desired to deliver the nails either head or point first into one or the other of said series of pockets, substantially as described.

9. In a nail-asserting mechanism, a nail-controller, means to present to said controller nails having their heads and points arranged indiscriminately, a series of pockets on said controller, a device to arrest temporarily the points of those nails coming to the controller point first, means to actuate said device and said controller, whereby the pockets therein may be provided with nails with their points in one direction, and means for actuating said controller to deliver all the nails from its pockets either head or point first.

10. In a nail-asserting mechanism, a nail-controller having a series of nail-receiving grooves, and a guide arranged longitudinally thereof and adapted to arrest the nails coming to said controller point first, means to move said guide to allow the point-first nails to continue their movement, and means to move said controller to enable the arrested point-first nails to drop into the grooves of the controller head first.

707,141. NAIL-ASSORTING MECHANISM. CHESTER C. SMALL, Newton, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed July 2, 1900. Renewed Feb. 3, 1902. Serial No. 3,807. (No model.)



Claim.—1. In a nail-asserting apparatus, the following instrumentalities, viz: a throat having a series of nail-passages, raceways leading nails to said passages, and a stop having a series of rests to support temporarily the heads of those nails which leave the raceways head first, and means to move said stop to remove said rests from under the heads of said nails, letting said nails, under the action of gravity, drop head first into said nail-passages, substantially as described.

2. In a nail-asserting apparatus, the following instrumentalities, viz: a throat having a series of nail-passages, and nail-receiving grooves in alinement with said passages, raceways leading nails into said nail-receiving grooves, and a stop having a series of grooves, the said stop normally occupying a position to close the said nail-receiving grooves, a gage, and means to move said stop to bring its grooves in line with the nail-receiving grooves of the throat, thus permitting the nails resting point first against said stop and lying in the said nail-receiving grooves to move longitudinally under gravity and meet the gage, the heads of such nails leaving the ends of the raceways and said nails under the action of gravity entering said nail-passages head first, substantially as described.

3. In a nail-asserting apparatus, the following instrumentalities, viz: a throat having a series of nail-passages, a stop having a series of notches and a series of rests, a raceway having a series of grooves to lead nails into said nail-passages, the heads of those nails leaving the raceway head first coming upon and being supported by said rests, the series of nails leaving said raceways point first bearing by their points against said stop between its notches, means to move said stop to remove said rests from under the nails arrested thereby head first, and to bring the notches of said stop opposite the ends of the nails directed point first to let said nails enter said notches, said nails by the act of entering said notches removing their heads from the said raceways, thereby permitting their heavier heads, while their points are temporarily supported, to turn down by gravity into the nail-passages, thus effecting the delivery of all of said nails through the passages of said throat head first, substantially as described.

4. In a nail-asserting apparatus, a throat having a series of passages a stop having a series of surfaces coöperating with each of said nail-passages, said stop having notches between the said surfaces, means to move said stop, and a gage to arrest the ends of those nails passing through said notches, substantially as described.

5. In a nail-asserting apparatus, a throat having nail-passages, and a movable stop having projections and rests and notches, said projections and rests sustaining respectively the points and heads of nails coming to said stop point and head first, combined with means to move said stop to remove the rests from under the heads of nails arranged head first and bring the notches of said stop opposite the points of the nails arranged point first, whereby the nails arranged head first no longer supported by said rests drop into said nail-passages and the nails arranged point first slide into said notches so that their heads may preponderate and enable them to drop head first into said nail-passages, substantially as described.

6. In a nail-asserting mechanism, raceways to receive and guide nails with their heads and points arranged indiscriminately, a device to arrest and sustain temporarily all the nails before they leave the raceways, and means to actuate said device to deliver all the nails pointing the same way.

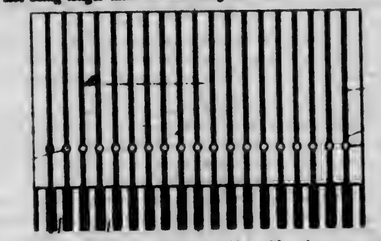
7. In a nail-asserting mechanism, raceways to receive and guide a series of nails, a series of passage-ways for the reception of said nails, a stop presenting an upright wall and a laterally-extended notched rest, a portion of said rest normally standing in the upper part of each of said passages to sustain the head ends of the nails passing from the raceways head first, and means to move said stop to put a notch at one side of a rest under the head of the nail that said head may drop through said notch and permit the nail to enter the passage.

8. In a nail-asserting mechanism, raceways to receive and guide a series of nails, a series of passages to receive said nails, a device having a series of projections separated by notches, said projections normally obstructing the entrance of point-first nails into said passages, and means to move said device to put a notched part thereof in line with the points of the nails which rest against said projections and are yet sustained by their head ends in said raceway, permitting the said point-first nails to enter said notches and slide therein sufficiently to enable the head ends of said nails to leave said raceways.

9. In a nail-asserting mechanism, raceways to receive and guide nails with their heads and points arranged indiscriminately, a device to arrest all the nails before they leave the raceways, and means to move said device to allow the head-first nails to drop from the raceways and to allow the point-first nails to travel on said device until their heads leave the raceways.

707,142. RACEWAY FOR NAIL-ASSORTING MACHINES. BENJAMIN F. HAYS, Salem, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed May 24, 1898. Serial No. 681,612. (No model.)

Claim.—1. A raceway presenting a groove provided in its bottom with an uncovered slot arranged in the general direction of said groove, said slot being longer than the nail being handled.



2. A raceway having a groove provided with a slot arranged in the general direction of said groove, with an enlargement at the end of said slot, said slot being longer than the nail being handled.

3. A raceway having a groove provided with a slot arranged in the general direction of said groove, and with an enlargement at the end of said slot.

4. A raceway having a groove provided with a tapered slot arranged in the general direction of said groove.

5. A raceway having a groove provided with a tapering slot located in the general direction of said groove, and a hole intersecting said slot, to operate substantially as described.

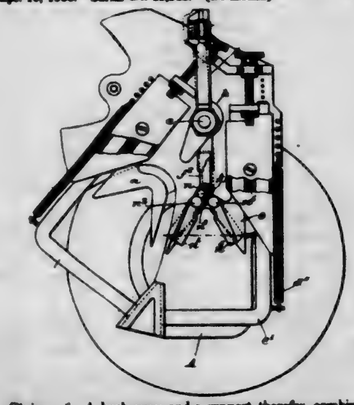
6. A raceway having a groove, and a tapering slot made therein in the general direction of the length of said groove, said slot removing more stock from one than from the other side of said groove.

7. A raceway having a groove provided with a slot arranged in the general direction of the groove, and a hole intersecting said slot, said hole being of greater diameter than the width of the groove and located in the bottom of said groove.

8. A raceway having a groove provided with a tapered slot formed therein in the general direction of the length of said groove, the wider end of said slot being located nearest the lower end of the raceway-groove.

9. A raceway having a groove provided with a tapered slot formed therein in the general direction of the length of said groove, said slot being of greater length than the nail being handled.

707,143. MEANS FOR DETAINING OR RELEASING TOP LIFTS IN HEEL-NAILING MACHINES. EDWIN A. LOCKE, Haverhill, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed June 19, 1896. Renewed Apr. 19, 1900. Serial No. 13,513. (No model.)



Claim.—1. A heel gage and a support therefor, combined with a detainer and means to actuate it that said detainer may at times overlap part of the space of the heel gage and at other times be moved to uncover said space.

2. A heel gage to receive the rear end of a top lift, and a support for said gage, combined with a detainer to overlap the edge of the heel gage and a top lift therein, and means to open said detainer to effect the release of a top lift.

3. A top-lift heel gage, a support therefor, and levers operatively connected together and constituting a top-lift detainer, combined with means to actuate said levers in unison to release the top lift.

4. A top-lift back gage, a support for said gage, and two levers pivoted on said back gage and operatively connected together to constitute a top-lift detainer, combined with means to actuate one of said levers, causing both of said levers to be moved in unison toward and from each other.

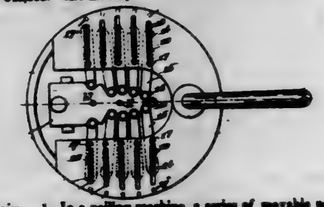
5. In a machine of the class described, a top-lift carrier, means for positioning a top lift on the carrier, a detainer extending over the top lift, and means to withdraw said detainer before the top lift is spanked onto a head.

6. A pivoted plate, a forked back gage for a top lift, a breast-gage acting against the breast of a top lift, means moving with said plate and operating automatically to retain the top lift temporarily in the back gage, and means to turn the top-lift-retaining means to release the top lift when it is to be spanked on an attached head.

7. The plate A provided with means for holding a head, and means having a back gage for holding a top lift; a lever pivoted above said plate and provided with a guide; and a link in said guide; combined with a top-lift detaining and releasing mechanism operatively connected with said link, said mechanism cooperating with the back gage of the top-lift holder, to at times overlap and hold, and to then release the top lift.

8. A back gage, and a support therefor, combined with a detainer located above and acting to partially cover the space in said back gage, a device connected with said detainer and means to actuate said device to move said detainer in a horizontal plane to uncover the space in the back gage.

707,144. **HEEL-NAILING MACHINE.** BENJAMIN F. MAYO, Salem, Mass., assignor, by mesne assignments, to the United Shoe Machinery Company, a Corporation of New Jersey. Filed Aug. 14, 1897. Serial No. 648,202. (No model.)



Claim.—1. In a nailing-machine, a series of movable nail-deliveries, means to support said deliveries, and a pattern adapted to cooperate with said deliveries to maintain the latter in position to accord with a desired form or outline of nailing, substantially as described.

2. In a nailing-machine, a series of movable nail-deliveries, means to support said deliveries, a series of nail-guiding tubes connected to and movable with said deliveries to supply nails thereto, and a pattern adapted to cooperate with said deliveries to maintain them in position to accord with a desired form or outline of nailing, substantially as described.

3. A plate, a series of deliveries mounted loosely thereon and springs to normally move said deliveries in one direction, combined with a pattern plate or device adapted to be applied to said deliveries to place them at proper distances apart and maintain them in the position designated by the contour of said pattern-plate, said springs operating to maintain the deliveries in contact with the pattern-plate, substantially as described.

4. In a nailing-machine, a series of nail-deliveries to inclose nails, means to support said deliveries, and a pattern to position simultaneously all said deliveries in the desired outline for nailing.

5. In a heeling-machine, a foot-plate, nail-inserting mechanism, a series of independent movable nail-deliveries, a series of flexible tubes connected each with one of said nail-deliveries and with said nail-inserting mechanism, and a pattern to position independently said nail-deliveries according to the arrangement of holes to be filled with nails and the outline of nailing desired.

6. In a nailing-machine, a series of spring-held nail-deliveries, and a pattern-plate adapted to act simultaneously on said position each delivery independently.

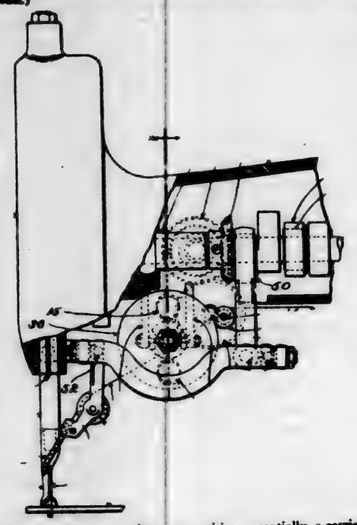
7. In a nailing-machine, a series of pivoted, slidable, normally yielding nail-deliveries, and a pattern-plate to simultaneously insure the placing of said nail-deliveries in position to enable nails to be arranged in accordance with a desired outline.

8. In a nailing-machine, a plate, a series of nail-tubes and arms sustaining them, a slot-and-pin connection between said plate and arms, and a pattern-plate acting against said nail-tubes to position them and their arms in accordance with the outline of nailing desired.

9. In a nailing-machine, a series of independently-movable nail-deliveries, combined with a pattern having a series of notches to receive and determine the position of said nail-deliveries to accord with a desired outline of nailing.

10. In a nailing-machine, a foot-plate comprising a bottom plate having an enlarged throat, a series of independent nail-deliveries adapted to be moved to place their lower ends in different portions of said throat, and a pattern to position said nail-deliveries with relation to said throat.

707,145. **TAKE-UP FOR SEWING-MACHINES.** FRANK W. MERRICK, Boston, Mass. Filed Aug. 11, 1900. Serial No. 726,871. (No model.)



Claim.—1. A rotary take-up comprising, essentially, a carrier making successive complete rotations in the same direction, means to rotate said carrier, diametrically opposite pins with which said carrier is provided, and means to occasion intersection of the path of the thread by that of the pins, whereby oppositely-extending loops are formed in the thread by the rotation of the pins, and subsequent separation of the said paths, whereby the said loops are released during the continued rotation of the carrier, substantially as described.

2. A rotary take-up comprising, essentially, a carrier, means to rotate the same, diametrically opposite pins with which said carrier is provided, means to project said pins transversely across the path of the thread, whereby the engagement of the pins with the thread operates to form oppositely-extending loops therein, and subsequently retract said pins transversely out of the said loops to release the latter, substantially as described.

3. A rotary take-up comprising, essentially, a carrier, means to rotate the same, diametrically opposite pins with which said carrier is provided, means to occasion intersection of the path of the thread by that of the pins, whereby oppositely-extending loops are formed in the thread by the rotation of the pins, and subsequent separation of the said paths, whereby the said loops are released during the continued rotation of the carrier, and a yielding follower to prevent flying of the thread after its disengagement from the pins, substantially as described.

4. A take-up for sewing-machines, comprising a rotary carrier, oppositely-located thread-engaging pins engaging with the thread to form oppositely-extending loops, means to project said pins to engage with the thread and retract the same to free the thread, and the yielding follower alongside said carrier.

5. A rotary take-up for sewing-machines, comprising oppositely-located thread-engaging pins engaging with the thread to form oppositely-extending loops, a head through which said pins work, a second head with which the said pins are connected, and operating means whereby projection of the said pins relatively to the head first mentioned is commenced to effect their engagement with the thread intermittingly.

6. A take-up for sewing-machines comprising a rotary carrier having a fixed head, oppositely-located thread-engaging pins working through said fixed head, a movable head with which the said pins are connected, and means to adjust the said pins toward and from each other, and means to operate the said movable head and thereby project and retract the thread-engaging ends of the said pins at the side of the fixed head.

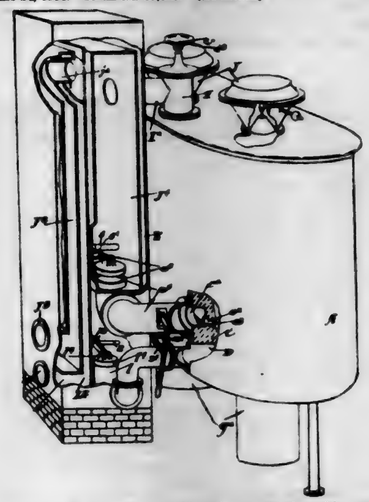
7. A take-up for sewing-machines, comprising a rotary carrier having radial guides, oppositely-located thread-engaging pins applied to the said guides, a head with which the said pins are connected, an adjusting-disk having cam-surfaces to regulate the distance of the said pins from each other, and means to operate the said head and thereby move the said pins endwise to engage and disengage the thread.

8. A take-up for sewing-machines, comprising a rotary carrier having a fixed head, oppositely-located thread-engaging pins working through said fixed head, a movable head with which the said pins are connected, means to operate the said movable head and thereby project and retract the thread-engaging ends of the said pins at the side of the fixed head, and the adjusting-plate having the eccentric-slots through which the said pins pass.

9. The rotary take-up consisting of the carrier comprising essentially the fixed head, the oppositely-located pins working through openings in the said fixed head, and the movable head with which the said pins are connected, means to rotate the said carrier, the rocker in operative connection with the said movable head, means to operate the rocker, and the spring-pressed follower at the side of the said fixed head.

10. The rotary take-up consisting of the carrier comprising essentially the sleeve, the head fixed to the said sleeve, the oppositely-located pins working through openings in the said fixed head, the movable head on the said sleeve having the said pins connected therewith, means to rotate the said carrier, the rocker in operative connection with the said movable head, means to operate the rocker, and the spring-pressed follower splined to the said sleeve.

707,146. **GAS-PRODUCER.** LEONARD L. MERRYFIELD, Toronto, Canada, assignor to Edwin James Chesbrough, trustee, and Economical Gas Apparatus Construction Company, Limited, Toronto, Canada. Filed June 24, 1901. Serial No. 65,855. (No model.)



Claim.—1. In a peat-gas machine, the combination with a suitable casing and lining therefor and two peat-burning chambers formed therein adjacent to each other and provided with suitable grates, feeding-retorts located above the peat-burning chambers and designed to contain peat preparatory to burning, a series of passage-ways extending upwardly from the upper portion of each peat-burning chamber circularly arranged and surrounding the retorts, and annular chambers connected therewith, a cross passage-way connecting the annular chambers, a series of passage-ways or flues leading radially outwardly near the bottoms of the peat-burning or fire chambers, annular passage-ways surrounding the bottom of the chambers and connecting with said radially-extending flues and gas-outlets from each annular chamber as and for the purpose specified.

2. In a peat-gas machine, the combination with a suitable casing and lining therefor and two peat-burning chambers formed therein adjacent to each other and provided with suitable grates, feeding-retorts located above the peat-burning chambers and designed to contain peat preparatory to burning, a series of passage-ways extending upwardly from the upper portion of each peat-burning chamber circularly arranged and surrounding the retorts and annular chambers connected therewith, a cross passage-way connecting the annular chambers, a series of passage-ways or flues leading radially outwardly near the bottoms of the peat-burning or fire chambers, annular passage-ways surrounding the bottom of the

chambers and gas-outlets from each annular chamber and valves for controlling the same and draft flues or pipes leading to beneath the grates and connected with the central gas-flues of each retort and valves controlling the same as and for the purpose specified.

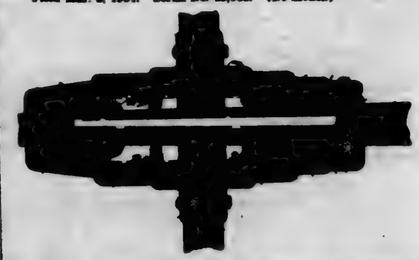
3. In a peat-gas machine, the combination with a suitable casing and lining therefor and two peat-burning chambers formed therein adjacent to each other and provided with suitable grates, feeding-retorts located above the peat-burning chambers and designed to contain peat preparatory to burning, a series of passage-ways extending upwardly from the upper portion of each peat-burning chamber circularly arranged and surrounding the retorts and annular chambers connected therewith, a cross passage-way connecting the annular chambers, a series of passage-ways or flues leading radially outwardly near the bottoms of the peat-burning or fire chambers, annular passage-ways surrounding the bottom of the chambers and gas-outlets from each annular chamber, and valves for controlling the same, and draft flues or pipes leading to beneath the grates and connecting with the central gas-flues of each retort and valves controlling the same and means whereby when the gas-outlet valve at the bottom of one chamber is open the draft-pipe at the bottom beneath the grate of the other chamber is likewise opened and the other two controlling the outlet and draft pipes are closed as and for the purpose specified.

4. The combination with two peat-fire chambers and the separate gas-flues surrounding each chamber at the bottom and communicating therewith, of the outlet-pipes leading from each gas-flues, the draft-pipes leading from beneath the grates, two shafts suitably supported one above the other, a cross-arm on one shaft connected by cross connecting-bars to the cross-arm on the lower shaft and arms on each shaft located on the same plane, cross-arms and caps connected to each arms and designed to extend over the ends of the gas-outlet pipes or flues and inlet draft-flues as and for the purpose specified.

5. The combination with two peat-fire chambers and the separate gas-flues surrounding each chamber at the bottom and communicating therewith, of the outlet-pipes leading from each gas-flues, the draft-pipes leading from beneath the grates, two shafts suitably supported one above the other, a sleeve on the upper cross-shaft, two arms connected to the sleeve and extending outwardly to one side of the upper cross-shaft, two arms secured on the shaft, the cross-arms on the bottom shaft, caps pivotally connected to one cross-arm and covering the ends of the draft-pipes and caps pivotally connected to one arm on the sleeve of the upper shaft and to an oppositely-extending arm on the shaft itself, screwed connecting-rods pivotally connected at the bottom to the ends of a cross-arm on the lower shaft and to one arm on the sleeve and one on the upper shaft, said connecting-rods being formed in two parts with lower socket portions and pins extending therethrough and the solid portion of the connecting-rods, means for manipulating such pins, so as to withdraw them and allow of the cross-arm on the lower shaft being operated independently of the arms on the upper sleeve and shaft as and for the purpose specified.

6. The combination with the outlet-flue and inner draft-flue, of the casing, a partition extending the major portion of the height of the casing into which such flue extends, a gas-conduit flue at one side of the partition, a corresponding flue on the opposite side of the partition, a pipe connecting the same, an outlet-pipe for the gas at the bottom of the outer gas-conduit flue, are inner air-flues surrounding the gas-conduit flues and forming passage-ways up around the outer gas-conduit flue and over the partition and down around the inner gas-conduit flue and communicating with the draft-tubes as and for the purpose specified.

707,147. **JOURNAL-BEARING.** ISAAC MEYERS, Winfield, Iowa. Filed Mar. 5, 1901. Serial No. 49,963. (No model.)



Claim.—1. The combination of a spindle, a hub journaled thereon and having a sleeve fitting around the spindle and projecting toward the inner end thereof, a cup-shaped flange secured to the spindle and projecting outwardly longitudinally thereof around said sleeve and into said hub, a loose bearing-ring interposed between said sleeve and cup-shaped flange

and surrounding said sleeve and having abutment against a part fixed with relation to said flange, and packing interposed between said ring and a part movable with the hub, substantially as set forth.

2. The combination of a spindle, a hub journaled thereon and having a sleeve formed integrally therewith and a portion overhanging and surrounding said sleeve and constituting therewith an enlarged packing-chamber, a cup-shaped flange secured to the inner end of said spindle and projecting over said sleeve and into said packing-chamber, a supporting and bearing flange carried by the hub at about the mid-length of said cup-shaped flange and bearing thereagainst and a packing surrounding said cup-shaped flange at a point between said second flange and the end of said sleeve, substantially as set forth.

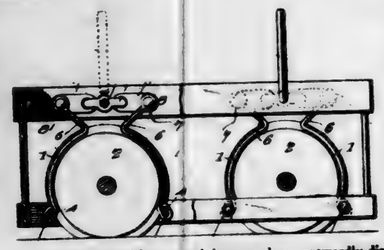
707,148. TOY BOAT. ERNEST E. MITCHELL, Washington, D. C., assignor to Hattie Ingraham, Wabasha county, Minn. Filed Feb. 24, 1899. Serial No. 706,712. (No model.)

Claim.—1. The combination with a separable structure comprising a base having the structure built thereon, said structure comprising a support having parts of the structure resting thereon, a plunger passed through the base and having a head adapted to receive an explosive cap, a projection on said support adapted to coöperate with the plunger-head to explode a cap carried by the latter, a spring arranged to throw the plunger upwardly, a perforation in the plunger, a pin passed through the perforation to hold the plunger retracted, wheels for the structure and connections between said wheels and pin to withdraw the latter and release the plunger, whereby it may rise and explode the cap and throw the parts of the structure apart.

2. A toy of the class described which represents a battle-ship provided with a central detachable deck portion on which the turrets, masts, davits and other deck-fixtures are loosely placed, and means upon and beneath said detachable deck portion for causing the representation of an explosion and the lifting of said detachable deck portion, substantially as shown and described.

707,149. BRAKE. ANDREW B. MOORE, Charlotte, Mich., assignor of one-half to Lyman H. McCall, Charlotte, Mich. Filed Mar. 19, 1902. Serial No. 98,602. (No model.)

Claim.—1. A brake comprising curved bars or shoes provided at one end with divergent guides arranged to carry the shoes inward and outward when the same are moved longitudinally, said bars or shoes being provided at their other ends with arms and designed to extend over the major portion of the periphery of the wheel to be engaged, and operating mechanism connected with the arms and adapted to move the brake shoes or bars both inward and outward and longitudinally, substantially as described.

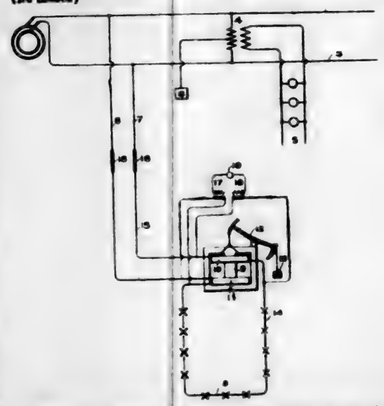


2. A brake comprising curved bars or shoes, outwardly-divergent guides arranged at one end of the bars or shoes and adapted to move the same inward and outward when the said bars or shoes are moved longitudinally, and operating mechanism connected with the other ends of the bars or shoes and adapted to move the same longitudinally and inward and outward, substantially as described.

3. A brake comprising curved bars or shoes provided at one end with divergent loops and having divergent arms at the other end, fastening devices passing through the loops, links connected with the arms, and a lever provided with arms connected with the links, substantially as described.

4. A brake comprising curved brake bars or shoes provided at one end with divergent loops and having divergent arms at the other end, fastening devices passing through the loops, a rock-shaft provided with arms, and links connecting the arms of the rock-shaft with the arms of the brake-shoes, substantially as described.

707,150. SYSTEM OF ELECTRICAL DISTRIBUTION. WALTER S. MOODY, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed June 6, 1898. Serial No. 119,416. (No model.)



Claim.—1. The combination of constant-potential mains, leads extending therefrom, windings adapted to generate reactive electromotive force in series with said leads, and translating devices connected in circuit between said windings.

2. The combination of constant-potential mains, leads extending therefrom, a reactive coil having windings in series with said leads, and translating devices connected in circuit between said windings.

3. The combination of constant-potential mains, leads extending therefrom, a reactive coil in circuit with said leads, and translating devices connected between portions of the winding of said reactive coil.

4. The combination of a grounded constant-potential supply system, a series circuit supplied therefrom, translating devices in said circuit, and inductively-related windings, one of said windings in circuit with one of the leads extending to said translating devices and another of said windings in circuit with the other lead extending to said translating devices.

5. The combination of a grounded constant-potential supply system, a series circuit supplied therefrom, translating devices in said circuit, and inductively-related relatively movable windings, one of said windings in circuit with one of the leads extending to said translating devices and another of said windings in circuit with the other lead extending to said translating devices.

6. The combination of a constant-potential system grounded at a neutral point, a divided reactive coil traversed by current therefrom, and translating devices connected in circuit between the divisions of said winding.

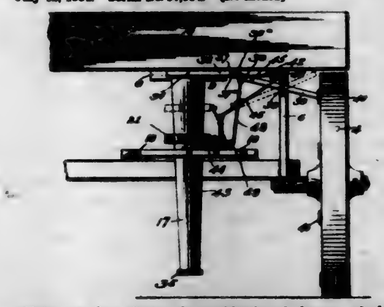
7. The combination of constant-potential mains, a divided reactive coil traversed by current therefrom, translating devices in circuit between portions of the winding of such divided reactive coil, and an indicating device responsive to relative reversal of polarity at the terminals of the portions of said winding.

8. The combination of a divided reactive coil, means for passing current therethrough, and means for indicating when the polarity of one portion of the winding of the reactive coil reverses with respect to the other portion of the winding of the reactive coil.

707,151. ADJUSTABLE MIRROR. MYER H. MEAD, Chicago, Ill. Filed Feb. 27, 1902. Serial No. 96,906. (No model.)

Claim.—In a device of the class described, the combination with a mirror having its sides provided with sockets, of a yoke adapted to embrace the mirror, having its end portions bent in and adapted to fit in the sockets on the mirror and having frictional engagement with the said sockets, an arm bent to project horizontally and having a vertical portion that is rotatably mounted, the horizontal portion of the arm being formed in telescoping sections d, d', d^2, the front section d having pivotal connection with the yoke while the remaining telescoping sections are tubular, a flexible connector 9 passing through the hollow sections of the arm and engaging the front section d, the rear end of the said flexible connector having attached thereto a button 11 and a stop 13 located in the section d^2 above the button, whereby the extent to which the sections may be separated is limited, substantially as described.

707,152. PLASTER. ROBERT NUMPHY, Canisteo, N. Y. Filed July 13, 1901. Serial No. 67,004. (No model.)

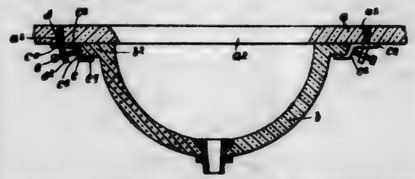


Claim.—1. In a plaster, the combination of a hopper, a feed-spout, valves at the top and bottom of the spout, a vibrating lever for imparting a sliding movement to the upper valve, a swinging lever connected to the lower valve, means for operating said vibrating lever, a connection between the two levers for effecting the simultaneous operation of the valves, means auxiliary to said levers for automatically and simultaneously retracting the same, a furrow-opener, furrow-coverers, a lever for simultaneously throwing said furrow-opener and furrow-coverers into and out of operation, and a connection between said lever and the vibrating lever for throwing said vibrating lever into and out of operation simultaneously with the furrow opener and coverers, substantially as described.

3. In a plaster, the combination with a frame, of a lever pivoted thereon, a furrow-opener adjustably connected with the lever, a flexible connection between said furrow-opener and a fixed part of the plaster, furrow-coverers pivoted to the frame, flexible connections between said furrow-coverers and the frame to limit the rearward movement of said coverers, flexible connections between the coverers and the lever, whereby when said lever is operated the furrow openers and coverers will be simultaneously thrown into and out of operation, and means for holding the said lever elevated, substantially as described.

4. In a plaster, the combination with a frame and hopper, of a feed-spout, a slide-valve between the hopper and the spout, a swinging valve at the lower end of the spout, a vibrating lever pivoted to the frame and connected with the slide-valve, a swinging lever connected with the swinging valve, a connection between the two levers for effecting the simultaneous operation of the valves, means for actuating the vibrating lever in one direction, springs for automatically retracting the levers, furrow opening and covering devices, and an operating-lever for simultaneously throwing said furrow opening and covering devices and the vibrating lever into and out of operation, substantially as described.

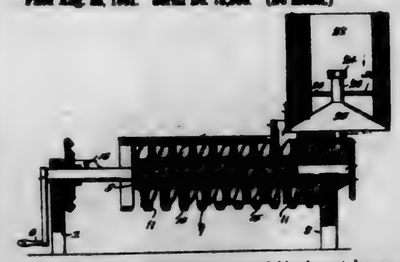
707,153. CLAMP FOR MARBLE WASH BOWLS OR BASINS. WILLIAM MCCLINTOCK, New York, N. Y. Filed Jan. 2, 1902. Serial No. 88,141. (No model.)



Claim.—1. The herein-described means for securing a bowl or basin to a marble slab or table comprising an angular clamp-piece, the ends of which are parallel and project in opposite directions and the central portion of which is at an angle to said ends, one of said ends being provided with a slot or opening, and a clamp bolt or member passed therethrough and adapted to be secured in the marble slab or table, said clamp bolt or member being provided in the outer end thereof with a set-screw which is passed therethrough and adapted to bear on the angular portion of the clamp, substantially as shown and described.

2. The herein-described means for securing a bowl or basin to a marble slab or table comprising a clamp c provided with parallel end portions c^2 and c^4 which project in opposite directions and which are connected by an angular portion c^3, the end portion c^2 being provided with a slot or opening c^5, and a clamp bolt or member passed therethrough and secured in the slab or table, the outer end of said clamp bolt or member being provided with a set-screw e, substantially as shown and described.

707,154. FRUIT-STEMMER. JAMES A. ROGERS, Lowry City, Mo. Filed Aug. 28, 1901. Serial No. 73,203. (No model.)



Claim.—1. The combination of a revolvable element having a peripheral spirally-disposed feed-channel, and a coacting cutter disposed against one side of said revolvable element, to retain fruit in said channel until it reaches the discharge end thereof and cut off the projecting stems

of the fruit during its passage through the channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, substantially as described.

2. The combination of a revolvable element having a peripheral spirally-disposed feed-channel, and a coacting cutting element, to retain fruit in said channel until it reaches the discharge end thereof and cut off the projecting stems of the fruit during its passage through the channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, and means to move one of said elements longitudinally, substantially as described.

3. The combination of a revolvable element having a peripheral spirally-disposed feed-channel, and a coacting cutter disposed against one side of said revolvable element, to retain fruit in said channel until it reaches the discharge end thereof and cut off the projecting stems of the fruit during its passage through the channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, and means to impart reciprocatory longitudinal movement to one of said elements, substantially as described.

4. The combination of a revolvable element having a peripheral spirally-disposed feed-channel, a coacting cutter disposed against one side of said revolvable element, to retain fruit in said channel until it reaches the discharge end thereof and cut off the projecting stems of the fruit during its passage through the channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, and means to feed fruit to the channel, substantially as described.

5. In a machine of the class described, the combination of a feed element having a feed-channel open on one side, and a coacting cutting element disposed against the open side of said channel, one of said elements being movable to urge fruit through the channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, whereby the projecting stems of the fruit will be cut off, substantially as described.

6. In a machine of the class described, the combination of a feed element, having a feed-channel open on one side, a coacting cutting element disposed against the open side of said feed-channel, said cutter comprising a plurality of transversely-disposed bars spaced apart and having cutting edges, and means to move one of said elements so that said cutting element crosses said channel, to cut off fruit-stems projecting therefrom, substantially as described.

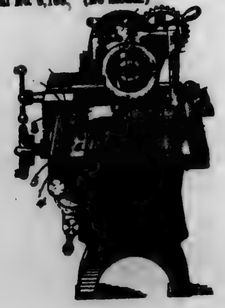
7. A stemming-machine, comprising a frame, a rotatable spiral feed-roller mounted thereon, a reciprocatory bowed cutting device embracing the feed-roller, means for operating the feed-roller, and an operative connection between the feed-roller and the cutting device for reciprocating the latter.

8. A stemming-machine, comprising an open substantially horizontal frame, an intermediate longitudinal spiral feed-roller rotatably mounted within the frame, a reciprocatory cutting device embracing the lower side of the roller and slidably mounted upon the frame, a removable cover embracing the top of the roller and carried by the cutting device, a transverse shaft mounted upon the frame and having opposite terminal crank-arms, connecting-links between the crank-arms and the cutting device, and an operative connection between the shaft and the feed-roller.

9. In a stemming-machine, the combination with a rotatable spiral feed device, of a reciprocatory cutting device embracing the feed device and having a plurality of bowed cutting-bars provided with cutting edges.

10. In a stemming-machine, the combination with a frame, of a rotatable spiral feed device, and a reciprocatory cutting device, comprising a knife-frame having opposite flanges slidably mounted upon the frame, and transverse bowed knife-bars embracing one side of the feed device and having their opposite edges beveled to cutting edges.

707,155. LATHE. JOHN L. GREGG, Buffalo, N. Y. Filed Feb. 23, 1900. Serial No. 6,168. (No model.)

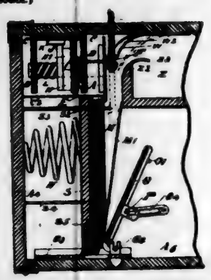


Claim.—1. In a lathe, a bed or frame having grooves, rails of hardened metal fitted in said grooves and having portions extending above the surface of the bed, a carriage having grooves on its under surface, rods of hardened metal fitted in said grooves and having depressions in which the extensions of the rails project.

2. In a lathe, a bed or frame having grooves, rails of hardened metal fitted in said grooves and having portions extending above the surface of the bed, a carriage having grooves on its under surface semicircular in cross-section, rods of hardened metal fitted in said grooves and corresponding in form to the semicircular cross-section of the groove; said rods having bottom depressions in which the extensions of the rails project.

3. In a lathe, a bed or frame having grooves, rails of hardened, tempered and true-ground metal fitted in said grooves, and having portions extending above the surface of the frame and a carriage having grooves on the under surface in which the extensions of the rails project.

707,156. MAGAZINE-CAMERA. WALTER G. PERES and HENRY G. M. FLETCHER, Hayle, England. Filed Aug. 31, 1901. Serial No. 73,905. (No model.)



Claim.—1. In a magazine-camera comprising a casing, a vertically-movable slide mounted therein, a follower mounted rearwardly of said slide, an axle mounted above said follower and a separating-disk connected with said axle and means whereby the axle is turned in opposite directions as the slide is raised and lowered, substantially as shown and described.

2. In a magazine-camera, a casing, a vertical and movable slide mounted therein, levers pivoted in front of said slide, a horizontal slide pivotally connected with the lower ends of said levers and through which the first-named slide is adapted to pass, means whereby the levers are held in a forwardly-directed position when the vertical slide is raised and in a backward position when said slide is lowered, devices for holding a pack of films adjacent to the back of the vertical slide and for pressing the same forwardly, an axle mounted above said devices, a separating-disk connected with said axle and devices whereby said axle is turned in opposite directions as the vertical slide is raised or lowered, substantially as shown and described.

3. In a magazine-camera, an axle, a separating-disk connected therewith, a vertical slide mounted in front of said axle, and devices whereby said axle is turned in opposite directions as said slide is raised or lowered, substantially as shown and described.

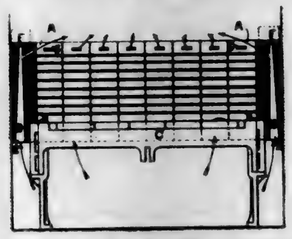
4. In a magazine-camera, a casing, a vertical and vertically-movable slide mounted therein, a horizontal slide mounted beneath said first-named slide, means for holding said levers in an upright position and against the vertical slide when the latter is in its lowest position and for holding said levers in a forwardly and upwardly inclined position when the vertical slide is in its raised position and means for pressing a pack of films against the back of said slide and for separating one of said films from said pack when said slide is raised, substantially as shown and described.

5. A magazine-camera provided with a specified vertical and vertically-movable slide G, a follower S, a horizontal slide O², levers pivotally connected with the front of said horizontal slide, an axle B mounted above said follower and movable forwardly and backwardly, a separating-disk connected with the front end of said axle and devices for turning said axle in opposite directions as said first-named slide is raised or lowered, substantially as shown and described.

6. A magazine-camera provided with a suitably-supported axle, a separating-disk A connected therewith, means for turning said axle in opposite directions, a cam connected partly with said axle and partly with the support thereof, and a spring L, mounted on said axle, substantially as shown and described.

7. In a magazine-camera, a casing, a vertically-removable slide mounted therein, devices for supporting a pack of films back of said slide and pressing the same forwardly, an axle mounted above said devices and provided with a separating-disk and devices for turning said axle in opposite directions as the slide is raised or lowered, substantially as shown and described.

707,157. FURNACE. JAMES REAGAN, Philadelphia, Pa. Filed May 27, 1902. Serial No. 109,163. (No model.)



Claim.—1. In combination with a furnace, a hollow block independent of the walls, sheets, linings, or grates, having an air-measuring outlet and adapted to be removed or replaced without interfering with or changing the walls, grates, or supports, substantially as described.

2. In a furnace a hollow block independent of the walls, sheets, linings, or grates, and adapted to be removed or replaced without in any way interfering with or changing the walls, grates or supports, and having a vertically-disposed tapering passage extending through its body with an opening at the upper end and an inclined outlet to deliver the air into the combustion-space above the fire as described.

3. In a furnace a hollow block independent of the walls, sheets, linings, or grates and adapted to be removed or replaced without in any way interfering with or changing the walls, grates, or supports having a vertically-disposed tapering passage extending through its body with an opening at the upper end and an inclined outlet to deliver air into the combustion-space above the fire, such passage and outlet being proportioned to deliver air at the outlet in such quantity as shall be desirable for the proper combustion of the fuel.

4. In a furnace hollow blocks independent of the walls, sheets, linings, or grates and adapted to be removed or replaced without in any way interfering with or changing the walls, grates, or supports and having each a vertically-disposed tapering passage extending through its body with an opening at the upper end and an inclined outlet to deliver air into the combustion-space above the fire, each passage being proportioned so as to deliver air at the outlet in such quantity as shall be desirable for the proper combustion of the fuel, said blocks being adapted to be constructed and applied to a furnace in a series of units so that any or all may be used at will.

5. In a furnace a hollow block independent of the walls, sheets, linings, or grates having a vertically-disposed tapering passage and an inclined outlet, a groove in one edge and a tongue upon the opposite edge thereof substantially as described.

6. In a furnace a hollow block independent of the walls, or of the grate, with a vertically-disposed tapering passage and inclined outlet, a groove in one edge and a tongue upon the opposite edge thereof and grooves upon the face thereof for the reception of ashes and at its lower end a transverse shoulder substantially as described.

7. A hollow block for furnaces having an air-passage in its body and a restricted air-measuring outlet communicating with said air-passage and adapted when in place to discharge air into, or toward the interior of, the body of gases within the combustion-space, substantially as described.

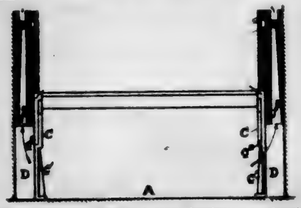
8. A hollow block for furnaces having a tapered air-passage in its body and an air-measuring outlet communicating with said air-passage and adapted when in place to discharge air into, or toward the interior of, the body of gases within the combustion-chamber substantially as described.

707,158. FURNACE. JAMES REAGAN, Philadelphia, Pa. Filed May 29, 1902. Serial No. 109,689. (No model.)

Claim.—1. A combination of a hollow block having a passage therethrough for the delivery of air, of a steam-superheating chamber situated at the discharge end of said passage and having a perforated wall of somewhat extended area lying in substantially the same plane as the face of said hollow block substantially as described.

2. A hollow block having in one of its faces a cavity communicating with the passage in said block, of a steam-pipe leading to said cavity, and a superheating-chamber communicating with said pipe and lying within said cavity, said superheating-chamber having a perforated face lying substantially flush with the face of the block and being so disposed within said cavity as to leave a passage for air around it, substantially as described.

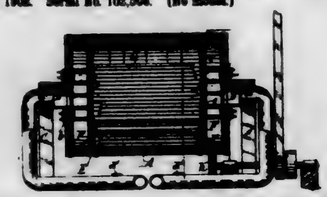
3. The combination of a series of adjacent hollow blocks each of which has a groove in its upper end, of a steam-pipe lying within said groove, a series of steam-superheating chambers situated within the bodies of the bricks and communicating with said steam-pipe, and air-discharge openings communicating with the passages in said blocks, substantially as described.



4. The combination with a furnace having a combustion-space provided with a series of adjacent hollow blocks in which are disposed air heating and feeding passages, of a series of perforated superheaters situated in the discharge ends of said passages and being exposed to the heat of the combustion-space.

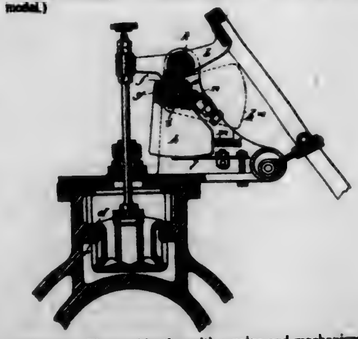
5. The combination with a furnace having a combustion-space provided with a series of adjacent hollow blocks in which are disposed air heating and feeding passages, of a series of perforated superheaters situated in the discharge ends of said passages, the said passages and superheaters being disposed at the front of the furnace above the feed-doors thereof and at the sides of the furnace, substantially as described.

707,159. METHOD OF POLISHING AND DRYING BROOM-HANDLES. CHARLES A. RIDLON, Alba, Mich., assignor of two-thirds to Willis K. Jackson and George A. Jackson, Buffalo, N. Y. Filed Apr. 12, 1902. Serial No. 102,506. (No model.)



Claim.—In the manufacture of broom-handles and similar articles, the herein-described polishing and drying method, which consists in rolling or tumbling a mass of the handles in an inclosing chamber, the axes of the handles being substantially parallel to that of the chamber, and simultaneously forcing opposing air-currents lengthwise through the interstices between the contiguous handles from opposite ends of the chamber, whereby the meeting air-currents produce a pressure which causes the air and moisture to be forced laterally through the mass of handles in different directions, substantially as set forth.

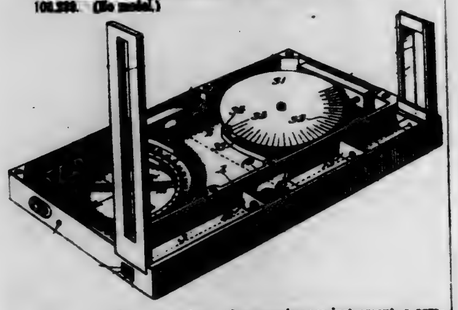
707,160. CUSHIONING DEVICE FOR VALVES. ERNST KOEP, Dresden, Germany. Filed Sept. 16, 1901. Serial No. 75,516. (No model.)



Claim.—1. The combination with a valve and mechanism for moving the same, of a movable weight and means on the valve-moving mechanism for moving the weight to check the movement of the valve.

2. The combination with the valve and mechanism for moving the same, of a movable weight and means on the valve-moving mechanism for moving the weight to check the movement of the valve, and means for returning the weight to its normal position in opening the valve.

707,161. SURVEYING AND RECONNAISSANCE INSTRUMENT. JOSEPH G. SALA, San Francisco, Cal. Filed May 20, 1902. Serial No. 108,329. (No model.)



Claim.—1. In a surveying and reconnaissance instrument, a compartment extending lengthwise of the instrument having end walls and intermediate transverse partitions, said end walls and partitions being provided with sight-apertures increasing in area from the eye-sight to the object-sight.

2. In a surveying and reconnaissance instrument, a compartment extending the length of the instrument having end walls and intermediate transverse partitions, said end walls and partitions being provided with sight-apertures increasing in area from the eye-sight to the object-sight, and wires across the object-aperture, adjusted to determine stadia measurements.

3. In a surveying and reconnaissance instrument, a compartment extending the length of the instrument having end walls and intermediate transverse partitions, said end walls and partitions being provided with sight-apertures increasing in area from the eye-sight to the object-sight, wires across the object-aperture adjusted to determine stadia measurements, and a spirit-level so arranged that the rays therefrom reflected will bisect the line of sight, and a prism-mirror to reflect the position of the bubble.

4. In a surveying and reconnaissance instrument, a compartment extending the length of the instrument, having end walls and intermediate transverse partitions, said end walls and partitions being provided with sight-apertures increasing in area from the eye-sight to the object-sight, wires across the object-aperture, sight-standards hinged to the end walls of the compartment having longitudinal slits therein, a mirror in the eye-sight standard having its backing removed in alinement with the slit in the sight, and a wire in the sight end of the compartment, substantially as and for the purposes specified.

5. In a surveying and reconnaissance instrument, a rectangular casing, a compass secured therein, an eye-sight standard, hinged to the casing, formed with a sight-slit, a mirror on the inside of the standard having the backing removed at determined distances in alinement with the sight-slit, an object-sight standard hinged to the other end of the casing and formed with a slot, and a wire strutched lengthwise in the slot.

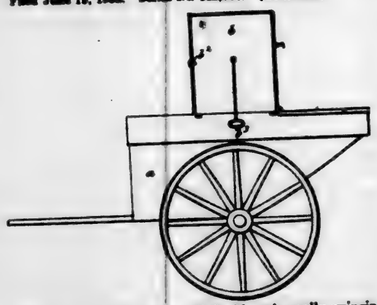
6. In a surveying and reconnaissance instrument, a rectangular casing, a compartment in the casing, transverse partitions in the compartment, the end walls of the compartment and the partitions being provided with alining sight-apertures, a vernier pivotally mounted, and a spirit-level mounted to turn with the pivot of the vernier, whereby the level is brought into a position making any desired angle with the horizontal within the limits of the prescribed arc.

707,162. LUMBER LOADING OR UNLOADING DEVICE. WILLIAM BARTEY, Stillwater, Minn. Filed May 22, 1902. Serial No. 108,631. (No model.)

Claim.—1. A loading and unloading device, comprising a base composed of longitudinal sills forming runways and cross-bars bracing the said sills, a derrick formed of converging beams secured together at their upper ends by means of a ring or band and having their lower ends hinged to said sills, side braces loosely connected to said beams, cables connected to the derrick, a windlass to which the cables are secured, said windlass being mounted upon the base, a sheave mounted upon the apex of said derrick, a hoisting-drum mounted upon the base, a hoisting-cable wound upon said drum, passed over said sheave and carrying a overhead cable having log-engaging hooks and placing-ropes secured to its ends, substantially as set forth.

2. The combination with two or more flat-bottom cars, of a hoisting-rig supported by runners adapted to be slid from one car-bottom to the other, a windlass carried by said rig, a pulley supported by one of the cars other than that upon which the rig is supported, a cable, one end of which is fixed to the frame of said rig, runs about said pulley and having its opposite end connected to said windlass whereby upon the rotation of the windlass in the proper direction the rig will be drawn from one car to the other, substantially as set forth.

707,163. ASH-CART. WILHELM SCHALLER, New York, N. Y. Filed June 19, 1902. Serial No. 112,263. (No model.)



Claim.—1. An ash-cart provided with an inwardly-swinging door, an outwardly-swinging lid, and means for attaching an ash-can to the lid, substantially as specified.

2. An ash-cart provided with an inwardly-swinging door hinged to the top of the cart-body, an oppositely-hung outwardly-swinging lid hinged in front of said door, and means for attaching an ash-can to the lid, substantially as specified.

3. An ash-cart provided with a hinged lid, a bracket having an inclined lower side, and a bent spring-influenced folding catch adapted to engage said side, substantially as specified.

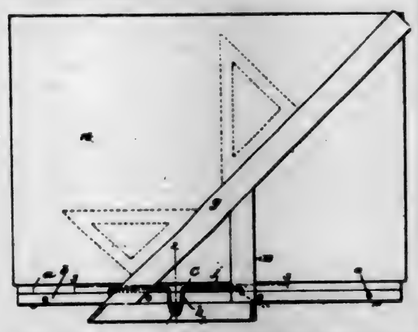
4. An ash-cart provided with a hinged lid, a bracket, a bent spring-influenced folding catch adapted to engage the bottom of an ash-can, a second catch adapted to engage the top of said can, and a spring-influenced cover adapted to close the can, substantially as specified.

5. An ash-cart provided with an inwardly-swinging door, an outwardly-swinging lid, means on the lid for supporting an ash-can, and a spring-influenced cover for closing said can, substantially as specified.

707,164. INSTRUMENT FOR MEASURING THE DEGREE OF EXPOSURE TO LIGHT. FELIX SCHMIDT, Berlin, Germany. Filed Feb. 17, 1902. Serial No. 94,511. (No model.)

Claim.—An exposure-meter comprising a tube one end of which is adapted to be placed light-tight against the eye, a concave lens at the other end, a plate of varying translucency and of uniform thickness adapted to be moved through the tube at right angles to its axis at a point between the eye and lens and in the focal plane of the latter, and a graduated scale on the edge of said plate, substantially as and for the purpose set forth.

707,165. DRAWING-BOARD LEG APPLIANCES. PHILIP SCHLAGETER, Sr., and ALONZO W. ALLEN, Streator, Ill., assignors of one-third to Philip Schlageter, Jr., Streator, Ill. Filed Feb. 11, 1902. Serial No. 93,858. (No model.)



Claim.—1. The combination of a drawing-board having a groove and a portion overhanging said groove, a slide arranged on the board and having a head bearing against one edge of the portion overhanging said groove, and a spring connected to the head of the slide and having a portion arranged below and in engagement with the portion of the board which overhangs the groove so as to hold the slide down on the board.

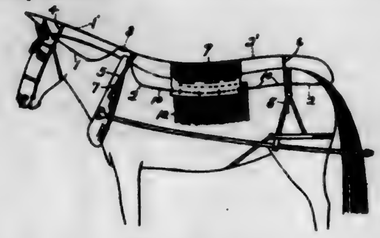
2. The combination of a drawing-board having a groove and a portion overhanging the same, a slide arranged on the board and having a head bearing against one edge of the portion overhanging said groove, and a spring connected at an intermediate point of its length to the head of the slide, and having oppositely-extending arms disposed in the groove of the board and terminating in hooks engaging the portion of the board which overhangs said groove.

3. The combination of a drawing-board having a groove and a portion overhanging the same, a slide arranged on the board and having a head bearing against one edge of the portion overhanging said groove, and also having a recess in the inner side of the head, and an aperture intersecting said recess, a spring having a loop disposed in the recess of the slide-head, and arms extending in opposite directions from the loop and disposed in the groove of the board and terminating in hooks engaging the portion of the board which overhangs the groove, and a removable pin resting in the aperture of the slide-head and the loop of the spring.

4. An attachment for drawing-boards comprising a strip having a groove, a straight edge connected to the strip and overhanging the groove thereof, a slide having a head bearing against the straight edge, and a spring connected at an intermediate point of its length to the head of the slide and having oppositely-extending arms disposed in the groove of the strip and terminating in hooks engaging the portion of the straight edge which overhangs said groove.

707,166. HORSE-PROTECTOR. ROSCOE H. SMITH, Kansas City, Kans. Filed Sept. 30, 1901. Serial No. 76,974. (No model.)

Claim.—In a horse-protector, the combination of a body-frame and a head-frame, the head-frame being pivotally connected to the body-frame and adapted to swing laterally with the movement of the horse's head, supporting-bows having their depending ends adapted to engage staples on a harness, said body-frame comprising the longitudinal central supporting-rib 2 and the longitudinal side supporting-ribs connected at the front and rear to the central rib, the head-frame comprising the central supporting-rib 1' and the side supporting-ribs connected therewith, and a covering carried by the bows and ribs of the two frames said covering having an adjustable portion at the point where the two frames are pivotally connected.



707,167. BEARING FOR SHAFTS OF MACHINES. ERNEST H. SMITH, Winchester, Mass. Filed Feb. 7, 1901. Serial No. 46,413. (No model.)

Claim.—In a machine-frame having a main member F through which its driving-shaft extends, the combination of that shaft; member F provided with a boss F' integral therewith and having a cylindrical interior; a sleeve with a cylindrical exterior to fit the interior of the boss F' and a cylindrical interior to fit the shaft; and means to hold the sleeve from moving in the cylindrical interior of the boss F' when in use substantially such as described.

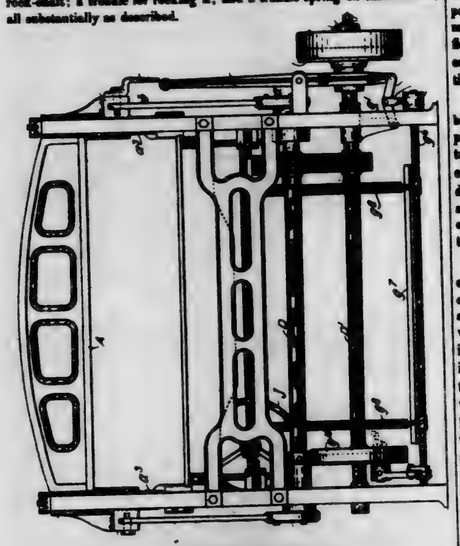
707,168. RECIPROCATING-BEAM MACHINE. ERNEST H. SMITH, Winchester, Mass. Filed Sept. 30, 1901. Serial No. 76,734. (No model.)

Claim.—1. In combination a beam; a driving-shaft; means connecting the shaft and beam; a power-driven wheel loose on the shaft; a clutch with one member fast to the power-driven wheel and the other member splined on the shaft; a shipping-lever fulcrumed near its middle and connected by its lower arm with the latter clutch member; a treadle connected with the lower end of the shipping-lever; and a cam carried by the beam and operating on the upper end of the shipping-lever; all substantially as described.

2. In combination a shaft; a beam; means connecting the shaft and beam; a sleeve on the shaft; means for fastening the sleeve to the shaft with provision for longitudinal adjustment of the sleeve on the shaft; a power-driven wheel loose on that sleeve; a clutch member fast to the power-driven wheel; a second clutch member splined on the shaft; a rock-shaft; a treadle for rocking it against the force of a spring; that spring; and means for connecting the rock-shaft with the second clutch member; all substantially as described.

3. In combination a beam; a driving-shaft; means connecting the shaft and beam; a power-driven wheel loose on the shaft; a clutch with

one member fast to the power-driven wheel and the other member splined on the shaft; a shipping-lever fulcrumed near its middle and connected by its lower arm with the latter clutch member; toggle-arms, one connected at its outer end with the lower end of the shipping-lever, the other connected at its outer end with a fixed support, and both connected at their inner ends with a link; that link connected at its upper end with the toggle-arms and at its lower end to one arm of a rock-shaft; that rock-shaft; a treadle for rocking it; and a treadle-spring on that treadle; all substantially as described.



707,169. SPRING-TIRE FOR VEHICLE-WHEELS. HENRY C SHEARMAN, Providence, R. I. Filed Aug. 5, 1899. Serial No. 601,746. (No model.)

Claim.—1. In combination, a wheel-rim having one central or two parallel grooves along its bed; a depression or well sunk below the surface of said bed or rim with an opening passing through the center of said depression; a tubular-tire or pneumatic-tube cover; and a boxing, occupying said depression or well in said rim, having a perpendicular shaft passing through said opening, said shaft having a bevel-gear head gearing with two bevel-gear-headed screws, threaded alike, passing through opposite sides of boxing for the purpose of closing the telescoping ends of the tire or pneumatic-tube cover with which ends said screws engage, substantially as described.

2. A flexible outer cover for a tubular-spring-tire or pneumatic-tire tube with ends, having the same outer periphery, provided with inwardly-projecting and transversely-extending shoulders forming flanges adapted to abut continuously together overlapping, substantially as shown and described.

3. A flexible outer cover for a tubular-spring-tire or pneumatic-tire tube with ends, having the same outer periphery provided with inwardly-projecting and transversely-extending shoulders forming flanges adapted to abut continuously together having embedded in, or made integral with, each of said ends a transverse band of spring-wire or suitable non-stretching material, substantially as described.

4. In combination with a detachable tubular spring-tire constructed of bands of spring material, a cover with its ends having the same outer periphery, adapted to abut together continuously over a telescoping spring-band, made an integral part of one end of the tire, to guide the opposite end of the tire-cover to its place of continuous abutting contact transversely over said telescoping spring-band when the tire is adjusted onto the rim of a wheel, and provided with suitable means for closing and fastening the same while on the rim of a wheel, substantially as described.

5. In combination with a tubular spring or other tire or flexible outer cover for a pneumatic-tire tube with free ends, having the same periphery, a rim-retaining band, or bands, extending around the longitudinal circumference of tire provided with a flexible band with ends secured at an extremity of said retaining band, or bands, and extending within and around the transverse end of tire to which it is attached, and projecting from said end to guide the opposite end of said tire or pneumatic-tire cover to its continuous transverse abutting contact over said flexible band in the adjustment of said tire to the rim of a wheel; the ends of said retaining band, or bands, being secured to the ends of said tire or pneumatic-tube cover, substantially as described.

6. In combination with a tubular spring or other tire or outer flexible cover for a pneumatic-tire tube with free ends, having the same outer periphery, a rim-retaining band, or bands, extending around the longitudinal circumference of tire, provided with a flexible band attached to each extremity of said retaining band, or bands, one being of such larger dimensions as to allow the other transverse band to telescope within it, and the ends of said tire, or cover, to which said ends of retaining band, or bands, together with their transverse bands are secured, to abut continuously over the aforesaid telescoping band, substantially as described.

7. In combination with a tubular spring or other tire, or flexible outer cover for a pneumatic-tire tube with free ends, having the same outer periphery, a rim-retaining band, or bands, extending longitudinally around said tire, provided with adjusting end plates screwed, or otherwise fastened, to the ends of said retaining band, or bands, to regulate its length; which end plates are provided with a flexible band conforming to the transverse curve of ends of tire, or tire-cover, one of which transverse bands being of such lesser diameter as to allow it to telescope within the other and the free ends of tire, or tire-cover, with same outer periphery to which said transverse bands are secured to abut continuously over the said telescoping band; said end plates being furnished with any suitable device to secure them together, substantially as described.

8. In a pneumatic tire, the combination of an outer flexible cover having free ends of the same outer periphery adapted to abut over a flexible transverse band attached to, or an integral part of, one end of cover; a longitudinally-extending rim-retaining band, or bands, with ends secured to ends of said outer cover; an inflatable inner tube; and suitable means for securing the ends of said retaining-band together, substantially as described.

9. A flexible or hollow tire with ends adapted to telescope together by abutting over or under a telescoping spring-band, and provided with a bevel-gear device consisting of a bevel-gear shaft gearing with two bevel-gear-headed screws which engage with the ends of the tire for the purpose of drawing and holding the ends together, substantially as described.

10. A tubular spring-tire constructed of bands of spring metal, or other suitable material, attached to an assembling rim band, or bands, with ends of said tire adapted to telescope by abutting over a telescoping spring-band, and provided with a bevel-gear attachment whereby the ends of the tire are drawn together or forced apart by the action of a bevel-gear shaft gearing with two bevel-gear-headed screws, threaded alike, which engage with the ends of the tubular spring-tire, substantially as described.

11. A flexible cover for a pneumatic tube, or tire, with ends adapted to telescope together by abutting over a telescoping spring-band, and provided with a rim band, or bands, and a bevel-gear attachment whereby the ends of cover are drawn together or forced apart by the action of a bevel-gear shaft gearing with two bevel-gear-headed screws, threaded alike, which engage with the ends of the rim band, or bands, substantially as described.

12. A tubular spring or other tire made attachable to, and detachable from, the rim of a wheel by means of a bevel-gear device consisting of a bevel-gear shaft gearing with two bevel-gear-headed screws which engage with the abutting ends of the tire, said ends abutting over a flexible band, and cause said ends to approach or recede from each other and also hold said ends firmly together over the said band by the turning of said bevel-gear shaft, substantially as described.

13. A tubular spring or other tire made attachable to and detachable from the rim of a wheel by means of a bevel-gear device consisting of a bevel-gear shaft gearing with two bevel-gear-headed screws which engage with the abutting ends of the tire and cause them to approach or recede from each other and also hold said ends firmly together by the turning of said bevel-gear shaft, substantially as described.

14. A detachable bevel-gear device for closing the ends of a tire, or other purpose, consisting of a boxing inclosed within which are geared three bevel-gear-headed shafts, two of which pass through opposite sides of boxing which furnishes a bearing for their bevel-gear heads; the external portion of each of the two separate shafts is threaded the same; the third bevel-gear has a solid or hollow shaft that, passing through an intervening side of the boxing, is provided with a thumb-piece or wrench which revolves the bevel-gear-headed screws, and will cause nuts, or other similarly-threaded objects, engaged one on ends of said bevel-gear-headed screws to simultaneously approach toward, or recede from, the boxing, substantially as described.

15. In combination, a bevel-gear device consisting of a boxing inclosed within which are geared three bevel-gear-headed shafts, two of which pass through opposite sides of boxing which furnishes a bearing for their bevel-gear heads, the external portion of each of the two separate shafts is threaded the same, the third bevel-gear has a hollow or solid shaft that, passing through an intervening side of the boxing, is provided with thumb-piece, or wrench, a nut carrying two longitudinally-extending guiding-arms engaged on each screw-threaded bevel-gear shaft, the extension guiding-arms of each nut sliding along the opposite sides of the boxing as the nuts approach or recede from each other by the turning of the bevel-gear-operating shaft, substantially as described.

16. The combination of the bevel-gear device consisting of a boxing inclosed within which are geared three bevel-gear-headed shafts, two of which pass through opposite sides of boxing which furnishes a bearing for their bevel-gear heads, the external portion of each of the two separate shafts is threaded the same, the third bevel-gear has a hollow shaft that, passing through an intervening side of the boxing, is provided with a thumb-piece or wrench, and a valve-stem of an inner pneumatic tube passing through said thumb-shaft; which combination allows the said thumb-shaft or operating-shaft to be revolved around said valve-stem without interfering with its functions, substantially as described.

17. A detachable tubular spring-tire consisting in combination of two series of spring-bands of metal or other suitable material, of circular or other form; said spring-bands to be placed at right angles to the plane of the tire and so adjusted and attached together that they lap edges and mutually support one another by interlocking in the same series; the spring-bands of the inner series being assembled on a rim-retaining-band to form a close series; the spring-bands of the outer series having the corners of each end cut out to form a shoulder, said ends of said ends attached to a separate assembling rim-band forming an open series of springs with edges below the shoulder abutting along the assembling rim-bands but with edges being overlapped and interlocked along the curvature of the springs; said outer open series closing over and clasping the inner series along its rim-assembling band and made attachable to and separable from it; together with a cover of canvas, rubber or other suitable material inclosing said tire, substantially as described.

18. A detachable tubular spring-tire constructed of two series of annular spring-bands, of metal or other suitable material, bent in circular or other form, placed at right angles to the plane of the tire; the edges of the spring-bands of the inner series being overlapped by the spring-bands of the outer series, causing them to mutually support one another, and both series attached to an assembling rim-band along the inner, or rim, circumference of tire with edges of springs in each series abutting along said assembling-band but only approximately abutting elsewhere along the transverse curve of tire to allow of a slight interplay of springs at tread when yielding to road contact, substantially as described.

19. A detachable tubular-spring-tire constructed of two series of separate spring-bands, of metal or other suitable material, bent in circular or other form, placed at right angles to the plane of the tire; the edges of the spring-bands of the inner series being overlapped by the spring-bands of the outer series causing them to mutually support one another; the ends of the spring-bands being attached to separate assembling rim-bands with their edges abutting along said assembling rim-bands in each series to form a tire continuously open along its rim-circumference, substantially as described.

20. In a tubular spring-tire, a series of spring bands, or loops, with their edges abutting along the inner rim-circumference of tire but overlapping edges along the transverse curve of tire—due to the width of each spring, or loop, being less at this place of their abutting contact with adjacent ones along the rim-circumference of tire than the remaining wider and shouldered portion of each spring, or loop; which overlapping of shouldered portion may extend sufficiently to cause the edges of alternate springs to approximately meet and form two series elsewhere than at place of abutting contact along the rim-circumference of tire, substantially as described.

21. A tubular spring-tire constructed of a series of spring bands, or loops, of metal or other suitable material, of circular or other form, attached to an assembling band, or bands, in such manner that said spring bands, or loops, abut along the said assembling band, or bands, but overlap edges along the transverse curve of tire—due to the width of each spring band, or loop, being less at place of attachment to said assembling band, or bands, than the remaining shouldered portion of each spring band, or loop, substantially as described.

22. A tubular spring-tire consisting of a series of spring-bands of metal, or other suitable material, of circular or other form attached to an assembling band or bands in such manner that said spring-bands abut along the said assembling band or bands but overlap edges along the transverse curve of tire—due to the width of each spring being less at place of attachment to said assembling band or bands than the remaining shouldered portion of each spring; which overlapping may extend sufficiently to cause the edges of alternate springs to approximately meet and form a series overlapped by intermediate springs elsewhere than at place of attachment to said assembling band or bands, substantially as described.

23. A tubular spring-tire consisting of a series of spring bands, or loops, of metal or other suitable material, of circular or other form, attached to an assembling band, or bands, by such a curvature of the springs, or loops, as will cause them to firmly clasp said assembling band, or bands, and secure such an interlocking of individual springs by means of each spring abutting against adjacent ones along the said assembling band, or bands, but overlapping edges along the transverse curve of tire—due to the width of each spring, or loop, being less at place of attachment to said assembling band, or bands, than the remaining shouldered portion of each spring, or loop; together with an adjusting end plate screwed or otherwise fastened to the ends of said assembling-band to regulate its length and secure the abutting contact of the spring-bands, substantially as described.

24. A tubular spring-tire consisting of a series of spring bands, or loops, of metal or other suitable material, of circular or other form, removably attached to an assembling band, or bands, by such a curvature of the springs, or loops, as will cause them to firmly clasp said assembling band, or bands, and secure such an interlocking of individual springs, or loops, by means of each spring, or loop, abutting against adjacent ones along the assembling band, or bands, but overlapping edges along the transverse curve of tire—due to the width of each spring, or loop, being less at place of attachment to said assembling band, or bands, than the remaining shouldered portion of each spring, or loop; which overlapping of shouldered portion may extend sufficiently to cause the edges of alternate springs to approximately meet and form two series of springs elsewhere than at place of attachment to said assembling band, or bands substantially as described.

25. In a tubular spring-tire, the combination of one or more series of springs with two assembling-bands; the springs to be removably attached to said assembling-bands by curving the ends of each spring so that they will firmly clasp, by approximately surrounding, said assembling-bands and allow each spring of a series to be moved along said assembling-bands in its attachment to, and removal from, them, substantially as described.

26. In a tubular spring-tire, the combination of two overlapping series of springs with two assembling-bands; the springs to be removably attached to said assembling-bands by curving the ends of each spring so that they will firmly clasp, by approximately surrounding, said assembling-bands and allow each spring of a series to be moved along said assembling-bands in its attachment to, and removal from, them, substantially as described.

27. In a tubular spring-tire, the combination of one or more series of springs with an assembling-band; the springs to be removably attached to said assembling-band by a reserveture of the springs at the place of attachment enabling them to partially surround and firmly clasp it, and allow said tire to be adjusted to and removed from the rim of a wheel without disturbing the attachment of springs to their assembling-band, substantially as described.

28. In a tubular spring-tire closed along its rim circumference, the combination of one or more series of springs, or spring-loops, with one assembling-band; the springs to be removably attached to said assembling-band by a reserveture of the springs at the place of attachment enabling them to partially surround and firmly clasp it, and allow said tire to be adjusted to and removed from the rim of a wheel without disturbing the attachment of springs to their assembling-band, substantially as described.

29. In a tubular spring-tire, the combination of an assembling band, or bands, on which the removable springs of a tire are assembled, together with an end plate screwed, or otherwise adjustably fastened, to each end of the assembling band, or bands, to secure the abutting contact of the springs along the said assembling band, or bands, substantially as described.

30. In a tubular spring-tire, or covering for a pneumatic-tire tube composed of overlapping sections, a tubular spring or section of said tire or covering provided with one or two recesses formed by curvatures in its material such as will enable it to firmly clasp an assembling band, or bands; the width of material being less at said curvatures than remaining portion of said spring or section—due to the removal of material along one or both edges to form a shoulder, substantially as, and for the purposes described.

31. A tubular spring-tire constructed of two or more series of spring bands, or loops, having a layer of suitable flexible material between two

series of said bands or hoops of said tire; which material may be confined to the tread-circumference of tire or extend laterally around it, substantially as, and for the purposes described.

32. A flexible cylinder for a wheel-tire, or other purpose, consisting of a series of annular bands, or hoops, which are provided with a reservature of transverse outline and which are of such inner width at said reservature as will allow said bands or hoops to abut at said reservature and interlock by overlapping transversely elsewhere, substantially as shown and described.

33. In a tubular spring-tire, or covering for a pneumatic-tire tube, made up of adjustable parts, a segmental portion of said tire or covering consisting of an outer and an inner transverse band with a layer of flexible and elastic material between, an edge or edges of either band of said segmental portion projecting beyond edge or edges of other band to form a telescoping band adapted to lap the edge of an adjacent segment, substantially as shown and described.

34. In combination with a tubular spring or other tire having a reserved recess along the tread-circumference of said tire, a cover with edges calculated to turn into and hug the sides of the said reserved recess, a tread-band having laterally-extending wings lapping over approximate edges of cover, said tread-band to be separable from said cover and calculated to hold said edges of cover firmly in place in the reserved recess along tread-circumference of tire and also to keep the wear and tear of road from said cover, substantially as described.

35. A tubular spring-tire in combination with a cover open along the tread and a detachable tread-band constructed to fit into a reserved recess along the tread of the tubular spring-tire and hold in place the edges of the said tire-cover, substantially as described.

36. In combination with a tubular spring or other tire having a recess along its tread-circumference, a cover consisting of two separate longitudinal parts—the outer edges of which are calculated to turn into and hug the sides of the said recess, the flanking portions of cover extending to any desired limit, together with a tread-band occupying the space between the approximate outer edges of cover within said recess to hold them in place, substantially as described.

37. In combination with a tubular spring or other tire or covering for a pneumatic tube having its outer transverse unbroken contour reserved to form a recess or groove longitudinally extending along its tread, which recess or groove shall have its side walls reserved to form a throat at tread narrower than interior of said recess or groove, at tread-band, occupying such recess or groove and firmly clasped by its walls, with laterally-extending wings which hug the curves of said tire both laterally and longitudinally and which may extend laterally to any desirable extent—even to meeting below said tire, substantially as shown and described.

38. In combination with a detachable tread-band, a tubular spring-tire constructed of one or more series of independently-acting and overlapping springs attached along the smaller longitudinal circumference of tire to a rim-retaining band, or bands, calculated to bind the springs of the tire to the rim of a wheel; said tire having a ⋃-shaped recess along its tread-circumference with its side walls formed by such a reservature in the body of each spring as to produce a throat at tread narrower than the interior of said recess to adapt it to hold securely in place by lateral or longitudinal pressure said detachable tread-band, substantially as described.

39. In combination with a tubular spring, or other, tire having a recess along its tread-circumference so reserved in sectional outline as to form a throat at tread narrower than the interior of said recess, a cover continuously open along the tread to admit of the insertion of the tire, and with its free edges calculated to turn into and occupy said recess, substantially as described.

40. A tire constructed of one or more series of independently-acting and overlapping springs attached along the smaller longitudinal circumference of tire to a rim-retaining band, or bands, calculated to bind the springs of the tire to the rim of a wheel; said tire having a ⋃-shaped recess along its tread-circumference with its side walls formed by such a reservature in the body of each spring as to produce a throat at tread narrower than the interior of said recess, substantially as and for the purposes described.

41. In combination with an inner pneumatic tube, a tubular spring-tire constructed of two series of independently-acting springs so arranged and attached to an encircling rim band, or bands, that the edges of the springs of a series are overlapped by the springs of the same or the other series; the springs of the outer series being so reserved and reserved at the tread of the complete tire as to form a continuous ⋃-shaped recess along the tread circumference of tire; the springs of the inner series not being reserved at the tread but calculated to confine the pressure of the inner pneumatic tube and allow the reserved recess of the outer series to perform its peculiar functions apart from, and independently of, any pressure derived from the inner pneumatic tube, substantially as described.

42. In combination, a tubular spring-tire constructed of independently-acting springs attached to a retaining band, or bands, calculated to bind the tire to the rim of a wheel, said tire having a recess along the tread-circumference formed by such a reservature in the body of each spring as to form a throat at tread narrower than the interior of said recess; an inner flexible but non-stretchable membrane, of circular transverse section, attached to said rim-retaining band, or bands, together with an inner inflatable pneumatic tube, substantially as described.

43. In combination with a tubular spring, or other flexible and elastic, tire or outer cover for an inner pneumatic-tire tube, having a ⋃-shaped recess along its tread-circumference formed by a depression or groove in the material of said tire or outer cover, which recess by a reservature of its side walls has a throat at tread narrower than the interior of said recess; a detachable tread-band occupying said recess with laterally-extending wings which hug the curves of said tire both laterally and longitudinally, which wings may extend to any desirable extent around the transverse curve of tire, substantially as described.

44. A tubular spring or other tire or covering for a pneumatic-tire tube having its outer transverse unbroken contour reserved to form a recess or groove longitudinally extending along its tread, which recess or groove shall have its side walls reserved to form a throat at tread narrower than interior of said recess, substantially as shown and described.

45. In a tubular spring-tire, or covering for a pneumatic-tire tube made up of adjustable parts, a spring or segmental portion of said tire or covering having its outer transverse unbroken contour reserved to form a recess or groove longitudinally extending along its tread, which recess or groove shall have its side walls reserved to form a throat at tread narrower than interior of said recess, substantially as shown and described.

46. A detachable tread-band or tire-cover having an inwardly-projecting longitudinal ⋃-shaped tongue with reserved sides caused by a thickening of its solid material along its inner or lower longitudinal periphery, and laterally-extending wings which following a curve in section may extend sufficiently to meet and form a cover open along its inner longitudinal circumference, substantially as, and for the purposes described.

47. In a sectional cover, for a tubular spring or other tire, provided with an inwardly-projecting longitudinal tongue with reserved sides caused by a thickening of its solid material along its inner or lower longitudinal periphery and laterally-extending wings which following a curve in section may extend sufficiently to meet, a section comprising a longitudinal half of said cover, substantially as shown and described.

48. The combination of a detachable tread-band, or tire-cover, having an inwardly-projecting longitudinal tongue, with a thickened periphery along its inner tread-circumference, and a series of transverse spring bands or leaves curved to clasp said tongue with edges abutting along said tongue but owing to a lesser width at abutting middle portion of each spring the remaining shouldered portions are caused to overlap edges of adjacent springs or leaves forming a flexible spring lining to the inner surface of said tread-band or cover, substantially as described.

49. The combination of a tread-band, or tire-cover, provided with a longitudinal tongue inwardly projecting from its inner tread-circumference and one or more series of laterally-extending springs or spring-leaves adjustably attached to said tongue by means of a reservature in the body of each spring enabling it to firmly clasp said tongue and allow of an interplay of the ends of springs either laterally or longitudinally, substantially as described.

50. A detachable, puncture-proof tread-band composed of one or more series of spring-leaves having a reserved recess at their middle portion occupied by the reserved inwardly-projecting tongue of its combination-parking which is made integral with or detachable from it, substantially as shown and described.

51. In a detachable, sectional tread-band provided with laterally-extending wings and a reserved inwardly-projecting longitudinal tongue, the combination of a segmental portion of said tread-band with a reserved spring-leaf, made integral with it or detachable from it, to form a puncture-proof section; which spring-leaf may project longitudinally if desired, to adapt it to overlap an adjacent section, substantially as shown and described.

52. Two or more series of transverse spring-leaves with edges abutting in each series but overlapped by spring-leaves of another series, each spring-leaf being provided with a reservature in its middle portion such as to enable it to clasp firmly abutting springs of overlapping series and form a flexible, sectional, puncture-proof tread-band, substantially as described.

53. A series of transverse spring-leaves provided with a reservature in their middle portion such as to allow edges of adjacent springs to abut along such reservature but, owing to a lesser width at such abutting reserved middle portion of each spring-leaf, the remaining shouldered portions are caused to overlap edges of adjacent spring-leaves forming a flexible sectional puncture-proof tread-band, substantially as shown and described.

54. Spring-leaves having a reserved recess at their middle convex, or concave, portion capable of clasping the tongue of a tread-band, or rim-band, which reserved middle portion is of lesser width than the remaining shouldered portions to permit edges of adjacent leaves of a series to abut at middle reserved portion but overlap at remaining shouldered portion, substantially as shown and described.

55. Spring-leaves having a reserved recess at their middle concave portion capable of clasping the tongue of a rim-band to firmly attach themselves thereto, substantially as shown and described.

56. Spring-leaves having a reserved recess at their middle convex portion capable of clasping the tongue of a tread-band to firmly attach themselves thereto and of clasping one another to form a flexible band of one or more series of spring-leaves, substantially as shown and described.

57. Spring-leaves having a recess at their middle convex or concave portion, which recessed middle portion is of lesser width than shouldered remaining portion to permit edges of adjacent leaves of a series to abut at middle recessed portion but overlap at remaining shouldered portion, substantially as shown and described.

58. A flexible cover, for a tubular spring or other tire, of unbroken transverse contour provided with an outwardly-projecting longitudinally-extending tongue at its outer rim-circumference having a reserved recess at its inner rim-circumference with its throat narrower than interior of recess caused by a thickening of material of said tongue enabling it to clasp a correspondingly-reserved rim band or tongue of tire at rim and act as a packing between tire and rim of wheel, substantially as shown and described.

59. A sectional cover, for a tubular spring or other tire, provided with an outwardly-projecting longitudinally-extending tongue at its outer rim-circumference having a reserved recess at its inner rim-circumference with its throat narrower than interior of recess caused by a thickening of material of said tongue enabling it to clasp a correspondingly-reserved rim band or tongue at rim of said tire and act as a packing between tire and rim of wheel, substantially as shown and described.

60. A longitudinal section of a cover, for a tubular spring or other tire, provided with an outwardly-projecting longitudinal tongue at its outer rim-circumference having a reserved recess at its inner rim-circumference enabling it to clasp a correspondingly-reserved tongue at rim of said tire and act as a packing between tire and rim of wheel; which section may be divided longitudinally at its middle portion if desired, substantially as shown and described.

61. A flexible cover, for a tubular spring or other tire, provided with an outwardly-projecting longitudinally-extending tongue at its outer rim-circumference having a reserved recess at its inner rim-circumference with its throat narrower than interior of recess caused by a thickening of material of said tongue enabling it to clasp a correspondingly-reserved rim band or tongue of tire at rim and act as a packing between tire and rim of wheel, said tongue being divided longitudinally through its center to produce a cover open at rim, substantially as shown and described.

62. A flexible cover, for a tubular spring or other tire, provided with a reserved inwardly-projecting longitudinal tongue at inner tread-circumference divided longitudinally through said tongue to produce a cover open at tread, substantially as shown and described.

63. In a sectional cover, for a tubular spring or other tire, provided with an inwardly-projecting longitudinal tongue at its inner tread-circumference with reserved sides caused by a thickening of its solid material along its inner or lower longitudinal periphery, and an outwardly-projecting longitudinally-extending tongue at its outer rim-circumference having a reserved recess at its inner rim-circumference with its throat narrower than interior of recess caused by a thickening of material of said tongue enabling it to clasp a correspondingly-reserved tongue of a tire and act as a packing between tire and rim of wheel, a section forming a longitudinal half of said cover, substantially as shown and described.

64. A detachable bevel-gear device for closing the ends of a tire, or other purpose, consisting of a boxing inclosed within which are geared three bevel-gear-headed shafts, two of which pass through opposite sides of boxing which furnishes a bearing for their bevel-gear heads; the external portion of each of the two opposite shafts is threaded the same; the third bevel-gear has a solid or hollow shaft that, passing through an intervening side of the boxing, is provided with a thumb-piece or wrench which revolves the bevel-gear-headed screws, and will cause nuts or other similarly-threaded objects, engaged one on each of said bevel-gear-headed screws to simultaneously approach toward, or recede from, the boxing; together with a loose bevel-gear placed opposite the thumb-shaft to steady the other geared shafts, substantially as described.

65. A bevel-gear device for closing the ends of a tire, or other purpose, consisting of a boxing inclosed within which, and completely housed by it, are geared two bevel-gear-headed shafts passing through adjacent sides of boxing which furnishes a bearing for their bevel-gear heads; the external portion of one of the shafts is threaded, the other solid or hollow shaft is provided with a thumb-piece or wrench which revolves the bevel-gearing and will cause a nut or other similarly-threaded object engaged on said bevel-gear-headed screw to approach toward, or recede from, the boxing, together with a loose bevel-gear placed opposite the thumb-shaft to steady the other geared shafts, substantially as described.

66. A detachable bevel-gear device for closing the ends of a tire, or other purpose, consisting of a boxing inclosed within which are geared three bevel-gear-headed shafts, two of which pass through opposite sides of boxing which furnishes a bearing for their bevel-gear heads; the external portion of each of the two separate shafts is threaded the same; the third bevel-gear has a solid or hollow shaft that, passing through an intervening side of the boxing, is provided with a thumb-piece or wrench which revolves the bevel-gear-headed screws, and will cause nuts or other similarly-threaded objects, engaged one on each of said bevel-gear-headed screws to simultaneously approach toward, or recede from, the boxing; said boxing being provided with oppositely and laterally projecting and longitudinally-extending flanges, substantially as described.

67. A flexible outer cover for a tubular-spring-tire or pneumatic-tire tube with ends, having the same outer periphery, provided with inwardly-projecting and transversely-extending shoulders forming flanges adapted to abut continuously together, and a projecting band of flexible material attached to or made integral with one end of cover to form a telescoping band over which the ends of tire-cover abut, substantially as described.

68. A flexible outer cover for a tubular-spring-tire or pneumatic-tire tube with ends, having the same outer periphery, provided with inwardly-projecting and transversely-extending shoulders forming flanges adapted to abut continuously together, having embedded in, or made integral with, each of said ends a transverse band of suitable non-stretching material together with a projecting band of flexible material attached to or made integral with one end of cover to form a telescoping band over which the ends of tire-cover abut, substantially as described.

69. A detachable tubular-tire or pneumatic-tire cover, of canvas or other suitable material, continuously open at rim with free ends adapted to abut together over a telescoping flexible band attached to or made an integral part of one end, substantially as described.

70. A detachable tubular-tire, or pneumatic-tire cover, of canvas or other suitable material, continuously open at rim, with free ends adapted to abut together over a telescoping flexible band attached to or made an integral part of one end, and provided with suitable means for adjustably attaching and securing together the edges at approximate ends, and the ends at approximate edges, of said tire, substantially as described.

71. A detachable tubular-tire, or pneumatic-tire cover, of canvas or other suitable material, continuously open at rim, with free ends adapted to abut together, and provided with a flexible open band at each approximate rim, edge, substantially as described.

72. A detachable tubular-tire, or pneumatic-tire cover, of canvas or other suitable material, continuously open at rim, with free ends adapted to abut together, and provided with a reinforcement of material with a flexible open band at approximate edges and ends, substantially as described.

73. In combination with a tubular-tire, or pneumatic-tire cover, having free ends adapted to abut together, one or more detachable rim-bands provided with means for regulating the amount of compression of material of tire or cover along said rim band or bands to secure an impact of material at tread on the complete transverse abutting contact of ends, substantially as described.

74. In combination with a tubular-tire, or pneumatic-tire cover, having free ends, one or more detachable rim-bands made attachable by adjustably securing ends of bands to ends of tire or cover to allow independent longitudinal movement of band and provided with means for regulating the amount of compression of material of tire or cover along said rim band or bands to secure a longitudinal impact or compression of material at tread on the inflation of tire or cover, substantially as described.

75. The combination of a tire or pneumatic-tire cover, having free ends, with a detachable rim-retaining band provided with an adjusting end plate at each end and each end plate, secured to an end of tire or cover, by eating as a sleeve being adapted to regulate the length of tire or cover at rim by being thrust toward or away from the other along the said retaining-band together with means for securing said end plate to said retaining-band when the tire is detached from the wheel-rim and its ends are disengaged, substantially as shown and described.

76. The combination of a tire or pneumatic-tire cover, having free ends and continuously open at rim, with two independently-acting detachable rim-retaining bands, one within each rim edge, provided with an adjusting end plate at each end of said bands and each end plate; secured to an end of the or cover at its rim edge, by eating as a sleeve being adapted to regulate the length of the tire or cover at its rim by being thrust toward, or away from, the other along the same retaining-band when the tire is detached from the wheel-rim and its ends are disengaged, together with a detachable nut or block at each end of tire securing to-

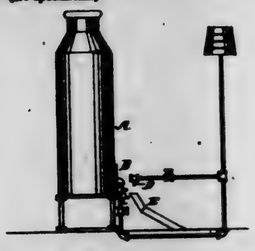
gether laterally the end plates of each end of tire or cover, substantially as shown and described.

77. In an open tire having free ends, the combination of a detachable nut or block with two laterally-placed adjusting end plates; the nut or block being provided with lateral flanges and made attachable to each end plate by dovetailing, substantially as shown and described.

78. In a pneumatic tire, the combination of an outer cover, of canvas or other suitable material, provided with free ends and one or more detachable rim-retaining bands made attachable by adjustably securing ends of band to ends of cover to allow independent longitudinal movement of band, substantially as shown and described.

79. In combination with a tubular-tire, or pneumatic-tire cover, provided with free ends, a transverse flexible band, preferably open at rim, over which the free ends of tire or cover are adapted to abut, substantially as described.

707,170. ARTIFICIAL SAND AND METHOD OF PRODUCING SAME. JOSEPH A. SEIBT, Pittsburg, Pa. Filed Oct. 21, 1901. Serial No. 79,482. (No specimens.)



Claim.—1. The method of reducing slag to a comminuted condition consisting in subjecting the molten slag to two streams of water applied simultaneously on opposite sides of the slag.

2. The method of producing slag-sand consisting in applying to the stream of slag as it flows from the furnace duplicate jets of water under pressure and on approximately opposite sides of the stream of slag.

3. As a new article of manufacture slag-sand produced solely by the action of water on approximately opposite sides of a stream of molten slag.

707,171. FOLDING TABLE. GEORGE R. SEIBERT, Fairfield, Ala. Filed Jan. 20, 1902. Serial No. 90,513. (No model.)

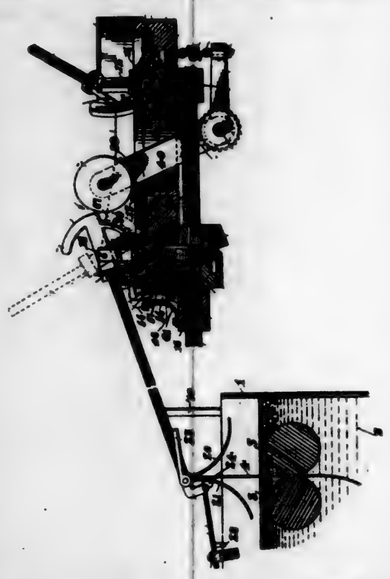
Claim.—A folding table, comprising a top, a channel-piece secured longitudinally in the center of the under side thereof, a pair of dogs extending in opposite directions pivotally mounted in said channel-piece, a stop-pin adjacent to the end of each dog in the channel-piece, legs arranged in pairs pivotally secured to the top and adapted to swing inward, a brace-rod carried by each pair of legs having its free end slidably mounted in the channel-piece, and a spring to hold each brace in the channel-piece at all times, to hold the braces in contact with the stop-pins while the dogs fall by gravity to engage the extreme ends of the braces when the legs are opened, and to hold the braces flat upon the dogs when the legs are closed.

707,172. PLATE-HANDLING MACHINE. RALPH R. STEARNS, Wheeling, W. Va. Filed June 22, 1901. Serial No. 65,574. (No model.)

Claim.—1. In a plate-handling machine of the character described, the combination with a support, of a plurality of plate-carriers movable therewith, and provided with gripping devices for engaging the edge of a plate, and means for imparting intermittent movement to said support to effect the successive presentation of the carriers in position to receive a plate.

2. In a plate-handling machine of the character described, the combination with a movable support, of a plate-carrier movable therewith, and independently movable thereon, and means controlled by the independent movement of the plate-carrier for effecting the movement of the support.

3. In a plate-handling machine of the character described, the combination with a movable support, of a plate-carrier independently movable thereon, and means for moving the carrier horizontally from the receiving-point to the delivering-point, said transferring mechanism being controlled by the vertical movement of the carrier.



4. In a plate-handling machine of the character described, the combination with a movable support, of a plate-carrier independently movable thereon, and means controlled by the individual movement of the carrier for effecting the intermittent movement of the support.

5. In a plate-handling machine of the character described, the combination with a movable support, of an independently-movable plate-carrier mounted thereon, and equipped with a gripping device disposed to grip the edge of a plate, means for effecting the independent movement of the plate-carrier, and means for operating the support to transfer the carrier from the receiving-point to the point of delivery.

6. In a plate-handling machine of the character described, the combination with a movable support, of a plate-carrier independently movable thereon, means for imparting independent movement to the plate-carrier, and means for moving the support to transfer the carrier from the receiving-point to the point of delivery, said last-named means being controlled by the independent movement of the carrier.

7. In a plate-handling machine of the character described, the combination with a movable support, of a pivoted plate-carrier mounted thereon, means for swinging said plate-carrier upon its pivot to lift a plate from the bath, and means for moving the support to transfer the carrier to the point of delivery.

8. In a plate-handling machine of the character described, the combination with a movable support, and a swinging plate-carrier movable therewith, of driving mechanism, gearing intermediate of the driving mechanism and carrier, to swing the latter for the purpose of lifting a plate from the bath, and independent gearing between the driving mechanism and support for moving the latter to transfer the carrier to the point of delivery.

9. In a plate-handling machine of the character described, the combination with a movable support and a plate-carrier mounted thereon for independent movement, of driving mechanism, a trip device controlling the operative connection between the driving mechanism and support, and means for operating said trip device through the independent movement of the carrier.

10. In a plate-handling machine of the character described, the combination with a movable support, driving mechanism and a trip device controlling the operative engagement between the driving mechanism and support, of a swinging plate-carrier mounted on the support and arranged to operate the trip device, and means for swinging said carrier.

11. In a plate-handling machine of the character described, the combination with a movable support, of a plurality of independently-movable plate-carriers movable therewith, and means for imparting an intermittent movement to the support to effect the successive presentation of the carriers in position to receive a plate.

12. In a plate-handling machine of the character described, the combination with an intermittently-movable support and operating mechanism therefor, of a plurality of plate-carriers movable with the support to effect the successive presentation of said carriers in position to receive a plate, and means for elevating said carriers to lift the plate from the bath.

13. In a plate-handling machine of the character described, the combination with an intermittently-movable support, and means for imparting such movement thereto, of a plurality of plate-carriers movable with the support and capable of independent movement thereon, said plate-carriers being designed for successive presentation in position to receive a plate by the intermittent movement of the support, and carrier-elevating mechanism located opposite the receiving-point for presentation to the carriers successively.

14. In a plate-handling machine of the character described, the combination with an intermittently-movable support, a trip device controlling the movement thereof and means for moving said support, of a plurality of carriers movable with the support and capable of movement independently thereof, means for operating the trip device by each of the carriers successively to effect the intermittent movement of the support, and means for successively elevating the carriers to cause them to withdraw the plates from the bath.

15. In a plate-handling machine of the character described, the combination with a movable carrier designed to engage and remove a moving plate from the bath, of carrier-operating mechanism disposed to be engaged by the carrier through the initial movement of the latter under the impulse of the moving plate.

16. In a plate-handling machine of the character described, the combination with a swinging plate-carrier disposed for engagement with a moving plate, of carrier-elevating mechanism arranged in the path of the carrier and designed for operative engagement therewith, as the carrier is swung under the impulse of the moving plate.

17. In a plate-handling machine of the character described, the combination with a movable plate-carrier, and carrier-operating mechanism for moving the carrier to remove a plate, of means for effecting the operative disconnection of the plate-carrier from its operating mechanism when undue resistance is opposed to the movement of the carrier.

18. In a plate-handling machine of the character described, the combination with a movable plate-carrier, of carrier-operating mechanism in frictional engagement therewith, whereby the movement of the carrier will be stopped when undue resistance is opposed thereto, said carrier-operating mechanism serving to move the carrier for the purpose of withdrawing the plate from the bath.

19. In a plate-handling machine of the character described, the combination with a movable plate-carrier, of carrier-operating mechanism comprising a friction-wheel having frictional contact with the carrier to operate the same, and means for yieldingly urging said elements into frictional engagement, said carrier-operating mechanism serving to move the carrier for the purpose of withdrawing the plate from the bath.

20. In a plate-handling machine of the character described, the combination with a swinging plate-carrier, of carrier-elevating mechanism comprising a friction-wheel disposed for contact with the carrier to elevate the same, and adjustable tension mechanism for yieldingly urging the friction-wheel into contact with the carrier.

21. In a plate-handling machine of the character described, the combination with a swinging plate-carrier, provided with a segment having an arcuate bearing-face, of carrier-elevating mechanism comprising a movable frame, a friction-wheel mounted on the frame and disposed for engagement with the bearing-face of the carrier, means for rotating said wheel to effect the elevation of the carrier, and tension mechanism connected to the frame.

22. In a plate-handling machine of the character described, the combination with a movable support, driving mechanism and means for effecting the intermittent engagement of the support with the driving mechanism, of a swinging plate-carrier mounted upon the support, a friction-wheel disposed to contact with the carrier to effect the swinging thereof, and gearing intermediate of the driving mechanism and said friction-wheel.

23. In a plate-handling machine of the character described, the combination with a movable support, driving mechanism, and means for effecting the intermittent engagement of the driving mechanism with the support, of a swinging plate-carrier mounted on the support and provided with an arcuate bearing-face, a friction-wheel disposed to engage with said bearing-face, a movable frame supporting said wheel, tension mechanism for urging the friction-wheel into engagement with the carrier, and gearing intermediate of the friction-wheel and driving mechanism.

24. In a plate-handling machine of the character described, the combination with a frame and a carrier-ring rotatably mounted thereon, of a plurality of plate-carriers mounted upon the carrier-ring, and means for imparting an intermittent movement to the ring to effect the successive presentation of the carriers in position to receive a plate.

25. In a plate-handling machine of the character described, the combination with a supporting-frame, of a carrier-ring rotatably mounted thereon, a plurality of independently-movable carriers mounted upon the ring, means controlled by the carriers for imparting intermittent movement to the carrier-ring, and means for imparting independent movement to the carriers.

26. In a plate-handling machine of the character described, the combination with a supporting-frame, of a carrier-ring rotatably mounted thereon, plate-carriers supported by the ring and disposed radially with respect thereto, and means for rotating the carrier-ring to effect the successive presentation of the carriers in position to receive a plate.

27. In a plate-handling machine of the character described, the combination with a supporting-frame, and a carrier-ring rotatably mounted thereon, of a series of swinging radially-disposed plate-carriers mounted on the ring for movement therewith, means for successively elevating the plate-carriers, and means for intermittently operating the carrier-ring.

28. In a plate-handling machine of the character described, the combination with a carrier-ring and plate-carriers mounted thereon, of a driving-shaft, a pinion loosely mounted on said shaft for engagement with the carrier-ring, a pawl for effecting an operative engagement between the pinion and shaft, and means for automatically operating the pawl intermittently to effect the intermittent operation of the carrier-ring.

29. In a plate-handling machine of the character described, the combination with a carrier-ring, and plate-carriers mounted thereon, of a driving-shaft, a pinion mounted loosely on the shaft and disposed to engage the carrier-ring, a pawl arranged to effect an operative engagement between the pinion and the driving-shaft and provided with a projection, and a pivoted trip provided with a cam designed to engage said projection for the purpose of moving the pawl.

30. In a plate-handling machine of the character described, the combination with a carrier-ring and an independently-movable plate-carrier mounted thereon, of a driving-shaft, a pinion loosely mounted on said driving-shaft and disposed for engagement with the carrier-ring, a pawl arranged to effect an operative engagement between the pinion and driving-shaft, said pawl being provided with a projection, and a pivoted trip provided with a cam disposed to engage the projection for the purpose of operating the pawl to release the pinion from the driving-shaft, said pivoted trip being disposed for retention by a plate-carrier to permit the pawl to move to its engaging position.

31. In a plate-handling machine of the character described, the combination with a carrier-ring, and plate-carriers thereon, of driving mechanism, a spring-pressed pawl controlling the engagement of the driving mechanism with the carrier-ring, said pawl being provided with a projection, a pivoted trip provided with a pawl-elevating cam and a stop-flange located at one end of the cam, and means for swinging the trip out of engagement with the projection through the movement of a carrier.

32. In a plate-handling machine of the character described, the combination with a carrier-ring and plate-carriers mounted thereon, of a driving-shaft, a pinion loosely mounted on the shaft and disposed to engage the carrier-ring, a sleeve fixed to the pinion, a spring-pressed pawl carried by the sleeve, a toothed collar fixed to the driving-shaft and disposed for engagement with the pawl, and means for operating the pawl to effect its engagement with and disengagement from said collar.

33. In a plate-handling machine of the character described, the combination with a movable support and a pivoted plate-carrier mounted thereon, of means for swinging said carrier to an upright position, and means for sustaining said carrier in its upright position except at the receiving-point and the point of delivery.

34. In a plate-handling machine of the character described, the combination with a supporting-frame, and an upstanding cam-flange, of a rotary carrier-ring mounted on the frame, and a plurality of swinging plate-carriers movable with the ring and resting on the cam-flange.

35. In a plate-handling machine of the character described, the combination with a supporting-frame and a cam-flange upstanding therefrom, said flange being cut away and provided with an abrupt inclined face adjacent to the receiving-point and provided with a depression defined by oppositely-disposed inclined faces opposite the delivering-point, a carrier-ring rotatably mounted upon said frame, swinging plate-carriers movable with the carrier-ring and designed to rest upon the cam-flange during the travel of the carrier-ring, and carrier-elevating mechanism located opposite the receiving-point.

36. In a plate-handling machine of the character described, the combination with a movable plate-carrier, of a pair of relatively movable grippers, a movable cam disposed to urge the grippers together, and means for operating the cam.

37. In a plate-handling machine of the character described, the combination with a plate-carrier and relatively movable grippers, of a cam

disposed to urge one of the grippers toward the other, and a weighted arm connected to said cam to move the same.

38. In a plate-handling machine of the character described, the combination with a movable plate-carrier provided with grippers, of a cam disposed to urge the grippers together, and means for automatically operating the cam through the movement of the carrier.

39. In a plate-handling machine of the character described, the combination with an intermittently-moving support and a plate-carrier provided with a fixed gripper and with a movable gripper, said movable gripper being provided with a weight disposed to urge it to its open position, of means for moving said movable gripper toward the fixed gripper in opposition to the weight.

40. In a plate-handling machine of the character described, the combination with a plate-carrier provided with a fixed gripper and with a movable gripper, said movable gripper being provided with a weight disposed to move it to its open position, a cam opposed to the movable gripper to move said gripper to its closed position, and a weighted arm connected to the cam to operate the same.

41. In a plate-handling machine of the character described, the combination with a support, of a movable plate-carrier provided with grippers designed to engage a moving plate emerging from the bath, carrier-elevating mechanism, means for automatically closing the grippers through the movement of the plate to be handled, and means for effecting an operative connection between the carrier and carrier-elevating mechanism through the continued movement of the plate after the closing of the grippers.

42. In a plate-handling machine of the character described, the combination with a supporting-arm, of a movable plate-carrier provided with grippers designed to engage a moving plate emerging from the bath, carrier-elevating mechanism, means for automatically closing the grippers through the movement of the plate to be handled, means for effecting an operative connection between the carrier and carrier-elevating mechanism through the continued movement of the plate after the closing of the grippers, transferring mechanism for transferring the carriers from the receiving-point to the point of delivery, and means for starting said transferring mechanism through the movement of the carrier under the impulse of the carrier-elevating mechanism.

43. In a plate-handling machine of the character described, the combination with a rotary support, of a plurality of plate-carriers mounted on the support for movement therewith as the support is rotated, said carriers being also mounted for movement independently of the support to lift a plate from the bath while the support is at rest, and means for rotating the support to present the carriers successively in the receiving position.

44. In a plate-handling machine of the character described, the combination with a movable support, of a plurality of independently-swinging plate-carriers mounted on the support for movement therewith, means for swinging the carriers to effect their elevation for the purpose of lifting the plates from the bath, and means for moving the support to effect the successive presentation of the carriers to the receiving-point.

45. In a plate-handling machine of the character described, the combination with a rotary support, of a plurality of plate-carriers independently pivoted upon said support and disposed radially with respect thereto, means for effecting the independent swinging of the carriers, and means for rotating the support to present the carriers successively at the receiving-point.

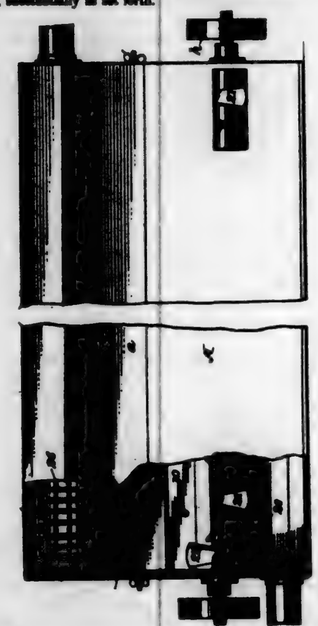
46. In a plate-handling machine of the character described, the combination with a movable support, of a plurality of independently-swinging plate-carriers mounted thereon, and grippers mounted at the outer ends of the said carriers to engage the plates, said plates being first elevated by the swinging of the carriers and subsequently transferred by the movement of the support.

47. In a plate-handling machine of the character described, the combination with a movable support, and means for moving the same, of a plurality of independently-swinging plate-carriers provided with grippers and mounted on the support for movement therewith, and means operated by the carriers for effecting the movement of the support.

48. In a plate-handling machine of the character described, the combination with a support mounted to rotate around a vertical axis, of a plurality of radially-disposed plate-carrying arms independently pivoted upon said support and provided with grippers at their outer ends, means for rotating the support, and mechanism established by said arms for operatively connecting said means with the support.

707,173. APPARATUS FOR SEPARATING STONES, &c. JOHN C. W. BRAMER, London, England. Filed July 1, 1901. Serial No. 66,922. (No model.)

Claim.—1. In an apparatus for separating stones, &c., from seed, the combination of an inclosing casing having a vertical partition dividing it into two chambers, a perforated plate supported in one chamber above the bottom thereof, means to feed the material to be treated onto one end of said plate, means to move it along said plate, means for introducing air under pressure below said perforated plate, and means to deflect the seed carried up by the air from the perforated plate into the other chamber, substantially as set forth.



2. In an apparatus for separating stones, &c., from seed, the combination of an inclosing casing having a cover formed of inclined sides, a vertical partition dividing said casing into two chambers communicating at their upper portions, a perforated plate in one chamber above the bottom thereof, means to feed the material to be treated to one end of said plate, means to move the material along said plate, means for introducing air under pressure below said plate, and a perforated plate in the upper part of the casing for the exit of the air, substantially as set forth.

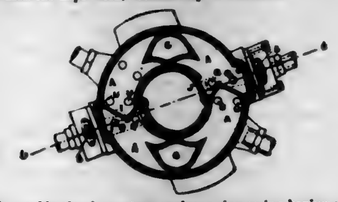
3. In an apparatus for separating stones, &c., from seed, the combination of an inclosing casing having a cover formed of inclined sides, a vertical partition dividing said casing into two chambers communicating at their upper portions, a deflecting-plate hinged to the upper edge of said partition and inclined over one chamber, a perforated plate supported in the latter chamber above the bottom thereof, means to feed the material to be treated to one end of said plate, means to move the material along said plate, means for introducing air under pressure below the said plate, and an air-exit in the inclined side of the roof above the other chamber, substantially as set forth.

4. In an apparatus for separating stones, &c., from seed, the combination of an inclosing casing having a vertical partition dividing it into two chambers, a perforated plate supported in one chamber above the bottom thereof, means to feed the material to be treated to one end of said plate, a shaft journaled above said plate, a series of separated blades connected to said shaft and arranged spirally thereon to move the material along said plate, means for introducing air under pressure below said plate, and means to deflect the seed carried up by the air into the other chamber, substantially as set forth.

5. In an apparatus for separating stones, &c., from seed, the combination of an inclosing casing having a vertical partition dividing it into two chambers, a perforated plate supported in one chamber above the bottom thereof, means to deliver the material to be treated to one end of said plate, means to move the material along said plate, means for introducing air under pressure below the plate, means to deflect the seed carried up by the air into the other chamber, a perforated plate in said casing for the exit of the air, and means to remove material tending to adhere to the latter plate, substantially as set forth.

707,174. ROTARY ENGINE. WILLIAM F. STARKEY, South Norwood, England. Filed Apr. 17, 1901. Serial No. 56,143. (No model.)

Claim.—1. In combination with a ring-casing having a channel, pivoted flaps extending across said channel from opposite sides and bearing against each other at their adjacent ends, said channel being of tapered cross-section, a piston similarly tapered and having curved sides against which the flaps work, substantially as described.



2. In combination in a rotary engine, a ring-casing having a channel therein, a piston working in said channel, a covering-plate above the channel connected with the piston and valve mechanism comprising a valve and a cam R attached to the covering-plate and arranged to operate the valve, substantially as described.

3. In combination, a ring-shaped casing having a channel therein, a piston in said channel, a shaft extending down through the casing, means for connecting the shaft with the piston extending down into the channel of the ring-shaped casing and an adjustable bearing for the lower end of the shaft whereby the piston may be adjusted vertically in respect to the channel, substantially as described.

4. In combination, a ring-shaped casing arranged horizontally, a shaft extending vertically and axially of the casing, a covering-plate, a piston connected with said covering-plate and extending into the channel of the ring-shaped casing and a fly-wheel on the shaft, the weight of the same tending to keep the covering-plate bearing upon its seat to keep the annular channel closed, substantially as described.

707,175. GLAZED STRUCTURE. JOHAN E. STUPPET, Boston, Mass., assignee to E. Van Bourdon Company, Boston, Mass., a Corporation of Massachusetts. Filed Apr. 19, 1902. Serial No. 103,711. (No model.)

Claim.—1. In a glazed structure the combination of a trough, a glass-support extending therefrom to above the main top level of its sides, a bolt extending crosswise the trough to hold the said support in adjusted position, a bolt headed to said glass-support and extending therefrom between the edges of the panes of glass, and a bow-nut and draw-nut to combine therewith for holding the panes of glass in adjusted position, substantially as described.

2. In a glazed structure, the combination of main troughs having cross-cut recesses, laterally-extending glass-supports resting at their ends within said recesses, the said supports being provided with side channels emptying into the main trough, the bottoms and exterior walls of which are adapted to fit against the bottom and walls of the said recesses in the main trough sides, and hold the said glass-supports in fixed position, substantially as described.

3. In a glazed structure, the combination of main troughs having cross-cut recesses, laterally-extending troughs resting with their ends within said recesses so as to pour into the main trough-channels, and comprising the exterior flanges *c*, the sides *c'*, the bottoms *c''*, and the interposed central glass-support having the sides c^3 and the glass-rest c^4, substantially as described.

707,176. BEARING. MARTIN STRIEBY, Erie, Pa. Filed Oct. 5, 1901. Serial No. 77,731. (No model.)

Claim.—1. A wheel, a bearing-tube fastened in said wheel to rotate therewith and having series of holes from end to end extending through the same from side to side, and wooden plugs filling said holes and having their ends flush with the inside bearing-surface of the said tube, whereby both metallic and wooden bearing and contact surfaces are obtained for said wheels, substantially as described.

2. In wheels, a metallic wheel having a cylindrical bore through its axis, a bearing-tube fixed in said bore and a metallic contact therewith from end to end, said tube having wooden plugs filling the same from end to end and flush with both the inner and outer surfaces thereof, and

wooden bearing-plugs set into the ends of said tube and flush with the end surfaces thereof, in combination with means for engaging the plugs in the ends of the tube, substantially as described.

707,177. HYDROCARBON-LAMP. GEORGE R. STILLMAN, Philadelphia, Pa. Filed Apr. 24, 1902. Serial No. 104,441. (No model.)

Claim.—1. A hydrocarbon lamp or oil foot, comprising a wick-chamber, the wall whereof is perforated, an oil-chamber arranged below the lower open end of said wick-chamber, a third chamber surrounding the perforated wall of said wick-chamber and arranged above the oil-chamber, the base of said third chamber being perforated, and a cap or housing arranged at the top of the foot and adapted to surround and receive the upper open end of the wick-chamber.

2. A lamp-foot, comprising an inverted-frusto-conical casing divided into upper and lower compartments by a horizontal perforated partition, and a perforated tube traversing the upper horizontal compartment and in open communication at its base with the lower compartment.

707,178. METHYLENE DI-ACETO DI-SALICYLIC ACID AND PROCESS OF MAKING SAME. SAMUEL L. SCHEIBER, Philadelphia, Pa. Filed May 10, 1902. Serial No. 106,068. (No specimens.)

Claim.—1. The new product described, which may be denominated methylene di-aceto di-salicylic acid, is white in color, is of microscopically small crystalline structure, tasteless, melts at about 145° centigrade, has the empiric formula $C_{19}H_{16}O_8$, and is insoluble in water but soluble in ether and alcohol.

2. The process described, of producing the di-acetyl derivative of methylene di-salicylic acid, which consists in subjecting the last-named body as a starting material to an acetylizing reaction by means of acetic anhydrid under heat and pressure, then crystallizing the resultant product and finally purifying the same.

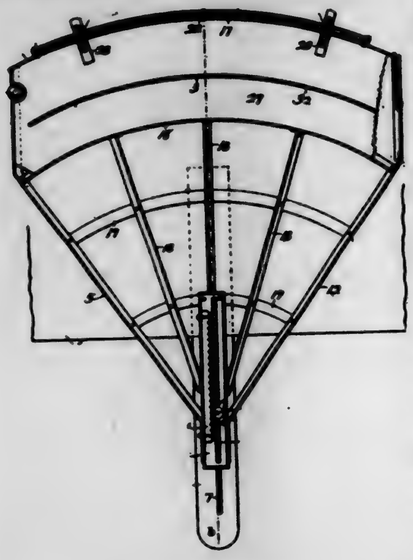
707,179. ATTACHMENT FOR CUTTING FELLIES OR THE LIKE. WILLIAM R. SCHNELL, Moberly, Mo. Filed May 16, 1902. Serial No. 107,632. (No model.)

Claim.—1. In a device for the purposes set forth, a center-shaped frame for carrying the stock, a hinged gate mounted at one side of said frame, and a segmental plate, adapted to be carried by said frame, for supporting the stock, the material of said plate being soft enough to be penetrated by the saw; substantially as described.

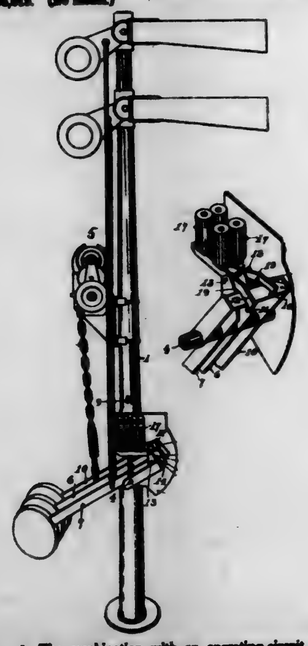
2. In a device for the purposes set forth, a center-shaped frame for carrying the stock, a segmental plate, adapted to be carried by said frame, for supporting the stock, the material of said plate being soft enough to be penetrated by the saw, curved guides, forming a curved slot, secured to the periphery of said frame, bolts passing through said slots, and guide-pieces 23 held by said bolts against said curved guides; substantially as described.

3. In a device for the purposes set forth, the combination with a saw-table of a longitudinally-slotted arm adapted to be secured to the table, a center-shaped frame for carrying the stock, a slotted casting secured to the converging sides of said frame, a pivot-bolt depending through the slot in said arm and having a portion projecting upwardly through the slot in said casting, a rack having inwardly-pointed teeth secured to one side of said casting, and a block having a perforation therein adapted to

receive the upper end of said pivot-bolt and a point adapted to enter between any two of said teeth; substantially as described.



707,180. SELECTOR FOR RAILWAY SIGNALING APPARATUS. JOHN D. TAYLOR, Buffalo, N. Y., assignor to Taylor Signal Company, Buffalo, N. Y., a Corporation of New York. Filed Nov. 16, 1900. Serial No. 36,613. (No model.)



Claim.—1. The combination with an operating-circuit, a signal-motor, gearing, and a plurality of signals, of a counterweight-lever, a set of signal-levers actuating said signals, mechanism for engaging any one of said signal-levers with said counterweight-lever, and a set of magnets to actuate said mechanism engaging said signal-levers with said counterweight-lever, substantially as and for the purposes set forth.

2. The combination with an operating-circuit, a signal-motor, gearing, and a plurality of signals, of a counterweight-lever, signal-levers and magnets in number corresponding to and in operation actuating said signals, mechanism for engaging said counterweight-lever with any one of said signal-levers actuated by said magnets, and means for closing any one of said magnets in the motor-circuit, substantially as and for the purposes set forth.

3. The combination with an operating-circuit, a signal-motor, gearing, and a plurality of signals, of a counterweight-lever actuated by said motor, signal-levers corresponding in number to and actuating said signals, clutches pivoted to said signal-levers, a pallet secured to said counterweight-lever capable of engaging any one of said clutches, magnets corresponding in number to said signals, means for closing any one of said magnets in the motor-circuit to throw its clutch into engagement with said pallet, substantially as and for the purposes set forth.

4. The combination with an operating-circuit, a signal-motor, gearing, and a plurality of signals, of a counterweight-lever actuated by said motor, signal-levers corresponding in number to and actuating said signals, a clutch pivoted to said signal-levers, a pallet secured to said counterweight-lever capable of engaging any one of said clutches, magnets corresponding in number to said signals, means for closing any one of said magnets in the motor-circuit to throw its clutch into engagement with said pallet, and means for disengaging said clutch from said pallet in the movement of the counterweight-lever to normal, substantially as and for the purposes set forth.

5. In combination with a signal-motor, an operating-circuit, a plurality of signals, a counterweight-lever, gearing connecting said counterweight-lever and said motor, signal-levers corresponding in number to the number of said signals, a corresponding number of magnets, clutches on said levers, a pallet on said counterweight-lever to engage said clutches, said magnets having one terminal connected with controlling-levers corresponding in number to said magnets, and the remaining terminals of said magnets being connected to one terminal of the signal-motor, to close any one of said magnets in the operating-circuit and throw its clutch into engagement with the counterweight-lever coincident with the energizing of the motor, substantially as and for the purposes set forth.

6. The herein-described system of operating a plurality of electric signals by the action of one signal-motor and one train of gearing, consisting of said motor and gearing and motor-circuit and a plurality of signals, of a series of magnets equal in number to said signals, controlling-levers for operating said signals connected with one terminal of each of said magnets, the other terminals of said magnets connecting with said motor, a set of levers connected to said signals, a counterweight-lever actuated by said motor, and a clutch on each one of said signal-levers to engage said counterweight-lever by energizing one of said magnets coincident with the closing of the circuit through the motor, substantially as and for the purposes set forth.

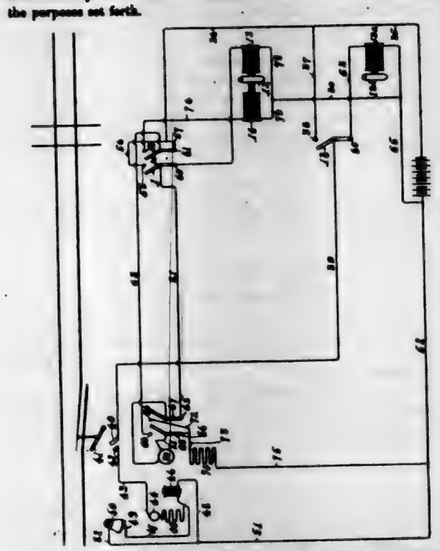
7. The herein-described system of electric railway-signals consisting of a plurality of signals, a single motor and mechanism connecting it with a single counterweight-lever, a counterweight-lever, signal-levers connected with said signals, a set of magnets corresponding in number to said signals, clutches carried by said signal-levers and adapted to engage with said counterweight-lever, means for energizing said magnets for throwing said signal-levers into engagement with said counterweight-lever, and means for mechanically disengaging said clutches on the return of the signal to normal, substantially as and for the purposes set forth.

707,181. RAILWAY SWITCHING AND SIGNAL INTERLOCKING APPARATUS. JOHN D. TAYLOR, Buffalo, N. Y., assignor to Taylor Signal Company, Buffalo, N. Y., a Corporation of New York. Filed Nov. 10, 1900. Serial No. 36,080. (No model.)

Claim.—1. The combination of an electric switch and a lever-bar actuating the same, consisting of a bar pivoted to said switch, a bar pivoted to said lever-bar, means for engaging said bars and means for throwing said bars in and out of engagement consisting of a solenoid and an armature actuated thereby, substantially as and for the purposes set forth.

2. The combination of an electric switch and a lever-bar actuating the same, consisting of a bar pivoted to said switch, a bar pivoted to said lever-bar, a solenoid energized by the indication-current of the system, an armature actuated by said solenoid, beveled notches in said bar pivoted to said lever-bar which take over said armature, a lug on said bar pivoted to said switch, said bar pivoted to said lever-bar being normally out of engagement with said bar pivoted to said switch and thrown into engagement by carrying a full part of said bar over said armature and finally thrown out of engagement by said solenoid carrying said armature under one of said beveled notches, substantially as and for the purposes set forth.

3. In combination with an interlocking mechanism, an electric switch, a lever-bar actuating the same, means for effecting the movement of one member of said interlocking mechanism by the movement of said lever-bar, locking the other connected members of said interlocking mechanism, a bar pivoted to said lever-bar, a bar pivoted to said switch, a solenoid energized by the indication-current of the system, an armature actuated by said solenoid, beveled notches in said bar pivoted to said lever-bar which engage over said armature, a lug on said bar engaging in a notch in said bar pivoted to said switch, said bars being normally out of engagement and thrown into engagement by carrying a full part of said bar having said beveled notches over said armature, and finally thrown out of engagement by said solenoid carrying said armature under one of said beveled notches, permitting the final throw of said lever-bar, and means for producing the final throw of said member of said interlocking mechanism by the final throw of said lever-bar, substantially as and for the purposes set forth.



4. In combination with an interlocking mechanism, an electric switch, a lever-bar actuating the same, means for effecting the movement of one member of said interlocking mechanism by the movement of said lever-bar, locking the other connected member of said interlocking mechanism, a bar pivoted to said lever-bar, a bar pivoted to said switch, a solenoid energized by the indication-current of the system, an armature actuated by said solenoid, beveled notches in said bar pivoted to said lever-bar which engage over said armature, a lug on said bar engaging in a notch in said bar pivoted to said switch, said bars being normally out of engagement and thrown into engagement by carrying a full part of said bar having said beveled notches over said armature, a step engaging said bar pivoted to said switch preventing the final movement of the lever-bar until released from said switch, said bars being finally thrown out of engagement by said solenoid carrying said armature under one of said beveled notches, permitting the final throw of said lever-bar, and means for producing the final movement of said member of said interlocking mechanism by the final throw of said lever-bar, substantially as and for the purposes set forth.

5. In combination with an electric switch and an interlocking mechanism, of a lever-bar actuating said switch and actuating a member of said interlocking mechanism to lock all conflicting switches and signals by the initial movement of said lever-bar, a bar pivoted to said switch, a bar pivoted to said lever-bar, a solenoid energized by the indication-current, an armature engaging said bar pivoted to said lever-bar, beveled notches in said bar taking over said armature, and having a lug capable of engagement in a notch in said bar pivoted to said switch, said levers being normally out of engagement, and thrown into engagement by the initial movement of the lever-bar carrying said bar pivoted thereto so that the armature engages a full part of said bar, means for preventing the final movement of the lever-bar while in engagement with said switch, means for preventing disengagement with said switch in the case of a false indication, and means for carrying said member of said interlocking mechanism to a final position by the final movement of said lever-bar after the same has been released by the action of the solenoid under the indication-current, substantially as and for the purposes set forth.

6. In combination with an electric switch and an interlocking mechanism, of a lever-bar actuating said switch and actuating said interlocking mechanism upon the initial movement of said lever-bar to look all conflicting switches and signals, a bar pivoted to said switch, a bar pivoted to said lever-bar, a double-throw solenoid, an armature reciprocated thereby and engaging said bar pivoted to said lever-bar, beveled notches in said bar taking over said armature and having a lug capable of engagement in a notch in said bar pivoted to said switch, said levers being normally out of engagement and thrown into engagement by the initial movement of the lever-bar in either direction, so that said armature engages a full part of said bar having said beveled notches, means for preventing the final movement of said lever-bar in either direction while in engagement with said switch, and means for carrying said member of said interlocking mechanism to a final position in either direction by the final movement of said lever-bar after the same has been released by the action of the solenoid under the indication-current, substantially as and for the purposes set forth.

7. In an interlocking switch and signal system, an interlocking mechanism, an electric switch, a lever-bar controlled in its initial movement by said interlocking mechanism, independent thereof in its intermediate movement, controlled in its final movement by a solenoid energized by an indication-current, and governing said interlocking mechanism in the final movement of said lever-bar, and means for preventing said final movement in case of a failure of indication, substantially as and for the purposes set forth.

8. In an interlocking apparatus for switches and signals, interlocking mechanism, an electric switch, a lever-bar, means for actuating said interlocking mechanism by the movement of said lever-bar, mechanism for controlling the throw of said lever-bar, a solenoid for controlling the action of said mechanism governing the mechanism controlling the throw of said lever-bar, and means for preventing the final movement of said lever-bar in case of a failure of indication, substantially as and for the purposes set forth.

9. The combination of an electric switch and a lever-bar actuating the same, of a bar pivoted to said switch, a bar pivoted to said lever-bar actuating said switch, means for throwing said bar so pivoted in and out of engagement, consisting of a solenoid and an armature actuated thereby, and means for preventing the final throw of said lever-bar in case of a failure of indication consisting of a pawl pivoted to the bar pivoted to said lever-bar and arranged to engage the armature of said solenoid and throw the same to the position which prevents the final throw of said lever-bar, substantially as and for the purposes set forth.

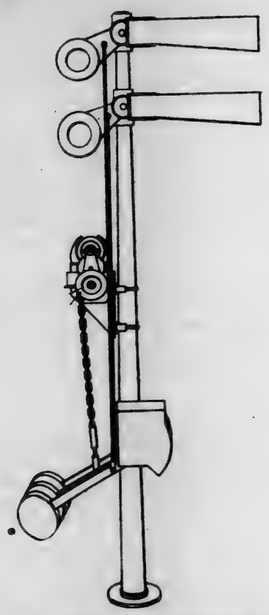
10. In an electric switch and signal apparatus the combination with an electric switch or signal, a lever-bar which actuates the same, a solenoid and its armature of means for controlling the apparatus comprising a bar pivoted to said switch and provided with a notch on its lower side, a bar pivoted to said lever-bar which takes over the upper end of said armature and is provided on one side with a lug adapted to engage with said notch and on the other so notched that said armature when actuated by the current will throw said lug in and out of engagement with the first-mentioned notch whereby the switch or signal is locked and released and the armature being subject to but slight friction is easily actuated by the current, substantially as and for the purposes set forth.

11. In an electric switch and signal apparatus the combination with an electric switch or signal, a lever-bar which actuates the same, a solenoid and its armature of means for controlling the apparatus comprising a bar pivoted to said switch and provided with a notch on its lower side, a bar pivoted to said lever-bar, which takes over the upper end of said armature and is provided on one side with a lug adapted to engage with said notch, and on the other side so notched that said armature when actuated by the current will throw said lug in and out of engagement with said first-mentioned notch, a pawl pivoted at one side of the notched portion of the last-mentioned bar and provided on the upper portion of one end with a shouldered lug adapted to engage with and be thrown by a lug secured to the casing of the switch-lever and adapted at its other end to engage with a lug on the armature whereby the armature is locked in its position and a failure of indication is prevented, substantially as and for the purposes set forth.

12. In an electric switch and signal apparatus, the combination with an electric switch or signal, a lever-bar which actuates the same, and a solenoid and its armature of means for controlling the apparatus comprising a bar pivoted to said switch and provided with a notch on its lower side, a bar pivoted to said lever-bar which takes over the upper end of said armature, and is provided on one side with a lug adapted to engage with said notch and on the other side so notched that said armature when actuated by the current will throw said lug in and out of engagement with the first-mentioned notch, a V-shaped head on the lower end of the armature, a bolt having an oppositely V-shaped head, a chamber in which said bolt is adapted to move, a spring contained within said chamber between the head of said bolt and the bottom of said chamber whereby the

bolt is pressed against the armature and when it is suddenly thrown by the actuating-current this pressure is sufficient to prevent a rebound of the armature and a consequent failure of indication, substantially as and for the purposes set forth.

707,182. **RAILWAY SIGNALING APPARATUS.** JOHN D. TAYLOR, Buffalo, N. Y., assignor to Taylor Signal Company, Buffalo, N. Y., a Corporation of New York. Filed Nov. 10, 1900. Serial No. 36,081. (No model.)



Claim.—1. In combination with a motor, a signal and a train of gearing actuating the signal, a reciprocating bar, pallets carried by said bar, a reciprocating block placed between lugs on said reciprocating bar, a contact-spring carried by said block, a spiral spring held between said block and one of the lugs of said bar, a detent engaging said block, a lug on said detent engaging with a lug on said reciprocating bar for releasing said detent and throwing said block by the action of said spiral spring, a disk mounted in rotation with said gearing, a wiper carried by said disk and adapted to engage with one of said pallets, said wiper and said pallet being so located with reference to each other as to produce the throw of the contact-spring which breaks the operating-circuit and closes the distant-signal circuit, substantially as and for the purposes set forth.

2. In combination with a motor, a signal and a train of gearing actuating the signal, of a reciprocating bar, pallets carried by said bar, a reciprocating block placed between lugs on said reciprocating bar, a contact-spring carried by said block, a spiral spring held between said block and one of the lugs of said bar, suitable means for engaging and releasing said block, a disk in rotation with said gearing, a wiper carried by said disk and adapted to engage with one of said pallets to produce the throw of the contact-spring which breaks the operating-circuit and closes the distant-signal circuit, a second disk mounted in rotation with said gearing, a wiper carried by said second disk and adapted to engage another pallet on said reciprocating bar for replacing said reciprocating bar and said contact-spring to their normal position, thereby reëstablishing the operating-circuit and closing the indication-circuit, substantially as and for the purposes set forth.

3. In combination with a motor, a signal, a train of gearing for actuating said signal, a circuit-controller, comprising a reciprocating bar, pallets carried by said bar, a disk in rotation with the gearing, a wiper on said disk and engaging one of said pallets to move said reciprocating bar to its reversed position, a second disk in rotation with said gearing, a wiper on said second disk engaging with another of said pallets to replace said reciprocating bar to its normal position, a third pallet carried by said reciprocating bar adapted to engage said first-mentioned wiper to replace said reciprocating bar to its normal position in case it has been carried beyond such position by an excess of movement due to momentum, substantially as and for the purposes set forth.

4. In combination with a motor, a signal and a train of gearing actuating the signal, a circuit-controller, comprising three contact-plates, a contact-spring adapted to engage at any one time with only two of said contact-plates, a reciprocating bar, a reciprocating block carrying said contact-spring, pallets carried by said bar, a disk in rotation with said gearing, a wiper on said disk engaging one of said pallets to move said reciprocating bar to its reversed position, a second disk in rotation with said gearing, a wiper on said second disk engaging with another of said pallets to replace said reciprocating bar to its normal position, means for adjusting said disk, a spiral spring interposed between said reciprocating bar and said reciprocating block adapted to throw said reciprocating block forward and thus break the operating-circuit and close the distant-signal circuit, a detent adapted to engage said reciprocating block and hold the same against the action of said spiral spring, a lug on said detent adapted to engage with the lug end of said reciprocating bar and to release said spiral spring at the close of the movement of the signal to safety, a third pallet carried by said reciprocating bar adapted to engage with said first-mentioned wiper to replace said reciprocating bar to its normal position in case it has been carried beyond such position by an excess of movement due to momentum whereby the operating-circuit is reëstablished and the indication-circuit closed, substantially as and for the purposes set forth.

707,183. **PACKING CASE OR BOX.** CAMILLE THIBAUT, St. Germain-en-Laye, France. Filed Mar. 26, 1902. Serial No. 100,116. (No model.)

Claim.—1. A wrapper comprising a body of flexible material plaited and readily compressible at a right angle to the length of the plaits, and a sheet of thin flexible fabric joined to the spaces of the plaits and foldable between the same.

2. A wrapper comprising a body acutely corrugated and readily compressible at a right angle to the corrugations, and sheets of thin flexible fabric joined to the spaces of the corrugations throughout the length thereof on both sides of the body and foldable between the same.

707,184. **TWIN-SAW SLABBING-MACHINE.** EDWIN E. THOMAS, St. Paul, Minn., assignor of one-half to Union Iron Works, Minneapolis, Minn., a Corporation of Minnesota. Filed Apr. 7, 1902. Serial No. 101,895. (No model.)

Claim.—1. The combination, with a steam-feed cylinder and its piston, of a sliding log-carriage connected with said piston, said carriage being adapted to accommodate a single log thereon, guides for said carriage, fixed and movable dogs provided on said carriage, power means within control of the sawyer at a fixed point for operating the movable dog at any point in the stroke or travel of said carriage, a lever and valve for controlling the movement of said piston, and twin circular saws between which said carriage and the log thereon are projected, substantially as described.

2. The combination, with a steam-feed cylinder, its piston and the valves for controlling the admission of steam to the same, of a longitudinally-sliding bar connected with said piston, a fixed and a movable dog provided on said bar between which the log to be slabbed is placed, an engine located on said bar and having its piston connected with said movable dog, power means within control of the sawyer at a fixed point for regulating the admission of steam to said engine and the movement of said movable dog at any point in the travel of said bar, and twin circular saws between which said bar and the log thereon are advanced to remove the slabs.

3. The combination, with a steam-feed cylinder, its piston and the valves for controlling the admission of steam thereto, of a sliding bar connected with said piston and driven thereby said bar being adapted to receive a log to be slabbed and form a carriage therefor, fixed and movable dogs provided on said bar and between which the ends of the logs are clamped, an engine provided on said bar and having its piston connected with the movable dog, a rocking rod upon stationary supports, an arm slidable on said rod and connected with the valve of said engine for regulating the admission of steam thereto, and a lever mechanism within control of the sawyer for rocking said rod and operating said engine-valve to operate said movable dog at any point in the travel of said bar.

4. The combination, with a steam-feed cylinder, its piston and the sawyer's valves for controlling the admission of steam thereto, of a longitudinally-movable carriage, fixed and movable dogs provided thereon and between which the ends of the log are clamped, a fluid-pressure motor device provided on said carriage and connected with said movable dog, and power means within control of the sawyer at a fixed point for regulating the admission of pressure to said motor device and controlling the movement of said dog at any point in the travel of said carriage.

5. The combination, with a steam-feed cylinder and its piston having a hollow piston-rod, of a carriage connected with said rod, a clamping mechanism, an engine having suitable connections with said hollow rod to receive steam-pressure therefrom, the pistons of said engine being connected to said clamping mechanism, means connected with the valve of said engine and within control of the sawyer at a fixed point for regulating the admission of steam to said engine-cylinder and controlling the movement of said clamping mechanism at any point in the travel of said carriage, and a sawyer's lever and valves for said feed-cylinder.

6. The combination, with the steam-feed cylinder, having suitable valves and a hollow piston and rod, of a sliding carriage-bar connected to said rod, a fixed and a movable dog provided on said bar and between which the log to be slabbed is clamped, an engine provided on said bar and having its piston connected with said movable dog for operating the same, a pipe connecting said hollow piston-rod with said engine, a rocking rod provided upon stationary supports near said bar, an arm splined thereon and connected with the valve of said engine to control the admission of steam thereto from said hollow piston-rod, suitable lever mechanisms within control of the sawyer for operating the valves of said feed-cylinder and for rocking said rod to control the movement of said movable dog, and twin saws provided near the forward end of said bar and between which it is driven with the log, substantially as described.

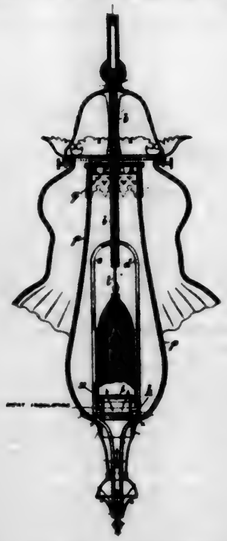
7. The combination, with a steam-feed cylinder having suitable valves, a piston and a hollow piston-rod, of a carriage whereon the log to be slabbed is placed, saws provided near the forward end of said carriage, means for moving said saws toward or from each other to change their set, means for clamping the log upon said bar to prevent movement of the same during the slabbing operation, power means provided on said carriage for controlling the clamping operation of said clamping means, and means within control of the sawyer at a fixed point for actuating said controlling means to operate the clamp connected therewith at any point during the movement of said carriage.

8. The combination, with a steam-feed cylinder, its piston and the sawyer valves, of a carriage, a clamping mechanism thereon, a fluid-pressure device provided on said carriage and connected with said clamping mechanism, and power means within control of the sawyer at a fixed point for regulating the admission of pressure to said motor device and controlling the movement of said clamping mechanism at any point in the travel of said carriage.

9. The combination, with a suitable base, of a steam-feed cylinder supported thereon and provided with valves for controlling the admission of steam thereto and a lever mechanism for operating said valves, of twin circular saws provided near one end of said cylinder, a longitudinally-slidable bar provided above said feed-cylinder, guides for said bar upon opposite sides of the saws, brackets whereon said guides are supported, a fixed and a movable dog provided on said bar and adapted to clamp the ends of the log placed between them, an engine mounted on said bar and having its piston connected with said movable dog, a rocking rod supported on said brackets near said bar, a sliding arm splined on said rod and connected with the valves of said engine, and a lever mechanism provided near the lever for operating said feed-cylinder valves and connected with said rocking rod for operating the same to actuate said movable dog at any point during the travel of said bar.

10. The combination, with a steam-feed cylinder provided with a hollow piston and rod and valves for controlling the admission of steam thereto, of a sliding bar provided above said feed-cylinder, suitable guides between which said bar is slidable, twin circular saws provided opposite the forward end of said bar, a fixed dog provided on said bar and having a sliding dog also mounted on said bar, guides between which said sliding dog is movable parallel to the direction of movement of said bar, an engine mounted on said bar and connected with said hollow piston-rod to receive steam therefrom, the piston of said engine being attached to said movable dog, a lever mechanism within control of an attendant for operating said feed-cylinder valves and for regulating the admission of steam to said engine at any point during the travel of said bar.

707,185. **INCANDESCENT GAS-LAMP.** GUSTAV TREIBEREUTER, Berlin, Germany. Filed Dec. 6, 1900. Serial No. 38,957. (No model.)



Claim.—1. In a gas-lamp, a burner, a mantle suspended over the same, a chimney and one or more gas-feed pipes between the chimney and the mantle, substantially as set forth.

2. In a gas-lamp, a burner, a mantle suspended over the same, a chimney, a burner-support forming a mixing-chamber and provided with air-inlets, an air-tight chamber forming part thereof and gas-pipes proximate the exterior of the mantle, passing through the chimney and the mixing-chamber to the air-tight chamber, means for admitting gas from the air-tight chamber to the mixing-chamber and a pilot-flame burner proximate the exterior of the mantle fed by one of said pipes, substantially as set forth.

3. In a gas-lamp, a mixing-chamber, a burner connected therewith and an incombustible mantle surrounding the burner, a bifurcated gas-feed pipe whose branches are in communication with said mixing-chamber, one of said branches provided with a jet-orifice proximate to the mantle, and means for arbitrarily controlling the supply of gas to the mixing-chamber; in combination with a chimney surrounding the burner and feed-pipe, for the purposes set forth.

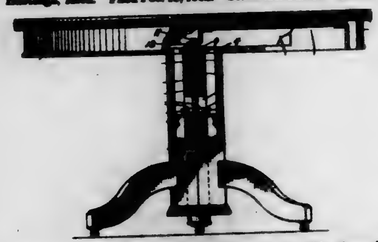
4. A gas-lamp comprising a mixing-chamber, a burner connected therewith, an incandescible mantle surrounding the burner and a bifurcated gas-feed pipe in communication with said mixing-chamber and having an extension between its branches provided with a hook for supporting the aforesaid mantle, for the purpose set forth.

5. In a gas-lamp, a mixing-chamber, a burner connected therewith, an incandescible mantle surrounding said burner, a bifurcated gas-feed pipe whose branches are in communication with said mixing-chamber, an extension from said pipe between its branches and a hook screwed into said extension for supporting the incandescible mantle; in combination with a chimney surrounding the mantle and feed-pipe, for the purpose set forth.

6. In a gas-lamp, a burner, a mantle suspended over the same, a chimney, gas-feed pipes in the form of a rectangle between the chimney and mantle, and a jet-orifice in one of said pipes proximate the lower portion of the mantle, substantially as set forth.

7. In a gas-lamp, a burner, a mantle suspended over the same, a burner-support of insulating material, a mixing-chamber forming part of the support and provided with air-inlets, a gas-chamber below and forming part of the mixing-chamber, a chimney, gas-pipes proximate the exterior of the mantle passing through the chimney and the mixing-chamber to the gas-chamber, one of said pipes provided with a pilot-flame orifice and a needle-valve to control the exit of gas from the gas-chamber to the mixing-chamber and burner, substantially as set forth.

707,186. PEDESTAL-EXTENSION-TABLE LOCK. BELL TYDER, Hastings, Mich. Filed Feb. 19, 1902. Serial No. 94,747. (No model.)



Claim.—1. In a pedestal extension-table, in combination with the separable parts and the pedestal parts pertaining thereto, respectively, an element mounted so as to be inclosed in the pedestal and to reciprocate vertically; a pair of links pivoted to said element; brackets on the pedestal parts at a substantial distance below the table-top in position to be encountered by the free ends of the links when the reciprocating element is moved endwise, whereby said ends after such encounter are limited to lateral movement, each bracket having means for engaging the encountering link whose lateral movement is toward the opposite pedestal part, to check such lateral movement, and means for giving endwise movement to the reciprocating element.

2. In a pedestal extension-table in combination with the separable parts and pedestal parts pertaining thereto respectively, an element mounted on the center leg and adapted to reciprocate vertically; a pair of links pivoted to said element; brackets on the pedestal parts at a substantial distance below the table-top in position to be encountered by free ends of the links when the reciprocating element is moved endwise; whereby said ends after such encounter are limited to lateral movement, each bracket having means for engaging the encountering link whose lateral movement is toward the opposite pedestal part, to check such lateral movement, and means for giving endwise movement to the reciprocating element.

3. In a pedestal extension-table, in combination with the separable parts and the pedestal parts pertaining thereto respectively, an element mounted so as to be inclosed by the pedestal adapted to reciprocate vertically; a spring tending to uphold it and a means for depressing it against the spring; a pair of links pivoted to said element, brackets on the pedestal parts respectively at a substantial distance below the table-top in position to be encountered by the free ends of said links when the reciprocating element is depressed and to guide said ends laterally; each bracket having therein for stopping the lateral movement of the link whose said movement is toward the opposite pedestal part, whereby continued depression of the reciprocating element draws the pedestal parts together.

4. In a pedestal extension-table in combination with the slide connecting-bridge, the separable parts and pedestal parts pertaining thereto respectively, an element carried by the slide connecting-bridge mounted so as to reciprocate vertically; a pair of links pivoted to the lower part of said element; brackets on the pedestal parts respectively at a substantial distance below the table-top in position to be encountered by the free ends of said links in the endwise reciprocation of the reciprocating element and to guide said ends laterally after such encounter, means by which the brackets respectively in such lateral movement of the links become engaged each with the link whose movement is toward the opposite pedestal part; and means mounted upon the slide connecting-bridge for giving endwise movement of the reciprocating element.

5. In a pedestal extension-table, in combination with the separable parts and the pedestal parts pertaining thereto respectively, an element mounted on the center leg and adapted to reciprocate vertically; a pair of links pivoted on said element and adapted to extend off therefrom in opposite directions; stops by which the links are checked at substantially horizontal position while left free to swing upward from such position; brackets on the pedestal parts respectively at a substantial distance below the table-top in position to be encountered by the free ends of the links when the reciprocating element is depressed, whereby said ends after such encounter are limited to lateral movement, the links having hooked ends for engaging such brackets when they encounter them whereby the further descent of the reciprocating element draws the pedestal members together; and means for locking the reciprocating element at its depressed position when the pedestal members are closed.

6. In a pedestal extension-table in combination with the upper structure consisting of the separable parts of the table and the extension devices which connect them, the pedestal parts pertaining to said separable table parts, respectively; devices for releasably connecting and disconnecting pedestal parts at a substantial distance below the table-top; means for operating such devices, comprising a thrust-rod connected thereto at its lower end; a pair of links connected together and connecting the upper end of said thrust-rod to the upper structure; means operating on the links to fold and straighten them, the links being free to fold in one direction, and a stop to arrest their folding in the other direction just beyond their straightened position.

7. In a pedestal extension-table in combination with the separable parts, the extension-slides connecting them, and the pedestal parts pertaining to the said separable table parts, respectively; devices carried by the extension-slides for releasably connecting and disconnecting the pedestal members at a substantial distance below the table-top; a means for operating said devices comprising a vertically-movable rod connected therewith at its lower end; pivot carried by the extension-slides; a pair of links connecting the upper end of the rod to such pivot, the links being free to fold in one direction and a stop to arrest their folding in the opposite direction just beyond their straightened position; and means operating on the links to fold and straighten them.

8. In a pedestal extension-table in combination with the separable members, the extension-slides connecting them and the pedestal members pertaining to said separable members, respectively; devices carried by the extension-slides for releasably connecting and disconnecting the pedestal members at a substantial distance below the table-top; a means for operating said devices comprising a vertically-movable rod connected therewith at its lower end; a pivot carried by the extension-slides; a pair of links connecting the upper end of the rod with such pivot, said links being free to fold in one direction, a stop to arrest their folding in the opposite direction just beyond their straightened position, and an operating-rod mounted on a table member at the side toward which the links fold without restraint, said rod having a slot adapted to engage the pivot which connects the links, and being mounted so as to be rocked in its bearings to effect engagement and disengagement of the slot with the pivot; whereby the longitudinal operation of the rod folds and straightens the links to effect the locking and unlocking of the device.

9. In a pedestal extension-table in combination with an upper structure consisting of the separable members and extension devices connecting them, the pedestal members pertaining to said separable members, respectively; devices carried by the upper structure for releasably connecting and disconnecting the pedestal members at a substantial distance below the table-top; means for operating said devices comprising a vertically-movable rod connected therewith at its lower end; a spring tending to uphold the rod, and devices carried by the upper structure operating on the upper end of the rod for depressing the rod and locking it in depressed position against the action of the spring, and means for unlocking it to permit the spring to lift the rod.

10. In a pedestal extension-table in combination with an upper structure consisting of the separable members of the table and the extension-slides which connect them; the pedestal members pertaining to said separable members, respectively; devices for releasably connecting and disconnecting the pedestal members at a substantial distance below the table-top; a means for operating such devices comprising a thrust-rod connected therewith at its lower end; a spring tending to uphold the thrust-rod; a pair of links connected together and connecting the upper end of the rod with the upper structure; a means operating on the links to fold and straighten them, the links being free to fold in one direction and a stop to arrest their folding in the other direction just beyond their straightened position.

11. In a pedestal extension-table in combination with the separable parts and pedestal parts pertaining thereto respectively, an element mounted so as to be inclosed in the pedestal and to reciprocate vertically, a pair of links pivoted to the said element at the lower part, brackets on the pedestal parts respectively at a substantial distance below the table-top arranged to be encountered by the free ends of the links in the endwise movement of the reciprocating element and to guide them laterally after such encounter, said brackets being provided with means for becoming engaged each with the link whose said movement is toward the opposite pedestal part; a pair of links pivoted together one of them being pivoted to the reciprocating element and the other to a pivot fixed with respect to the support of said reciprocating element substantially in line therewith; a spring to uphold the reciprocating element and fold the links, and means extending under the table-top for forcing the pivot at which the links are connected together toward the line of the other pivot of said links, to depress the reciprocating element against the action of this spring.

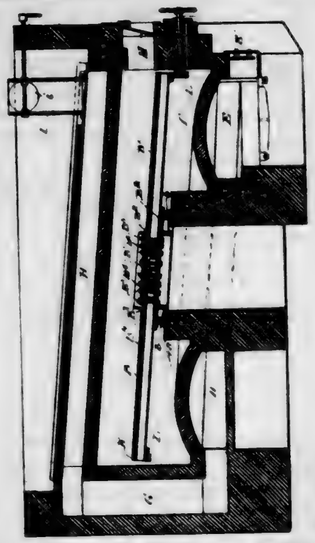
12. In a pedestal extension-table in combination with the separable parts and pedestal parts pertaining thereto respectively, an element mounted so as to be inclosed in the pedestal and to reciprocate vertically, a pair of links pivoted to the said element at the lower part, brackets on the pedestal parts respectively, at a substantial distance below the table-top, arranged to be encountered by the free ends of the links in the endwise movement of the reciprocating element and to guide them laterally after such encounter, said brackets being provided with the means for becoming engaged each with the link whose said movement is toward the opposite pedestal parts a pair of links pivoted together one of them being pivoted to the reciprocating element and the other to a pivot fixed with respect to the support of said reciprocating element substantially in line therewith; a spring to uphold the reciprocating element and fold the links, and means extending under the table-top for forcing the pivot at which the links are connected together past the line of the other pivots of the links and a stop to arrest such movement when said line is passed by said pivot.

13. In a pedestal extension-table in combination with the separable parts and pedestal parts pertaining thereto respectively an element mounted so as to be inclosed in the pedestal and to reciprocate vertically; a pair of links pivoted to the said element at the lower part, brackets on the pedestal parts respectively at a substantial distance below the table-top arranged to be encountered by the free ends of the links in the endwise movement of the reciprocating element and to guide them laterally after such encounter, said brackets being provided with means for becoming engaged each with the link whose said movement is toward the opposite pedestal part; and the pair of links pivoted together one of them being pivoted to the reciprocating element and the other to a pivot fixed with respect to the support of said reciprocating element substantially in line therewith; a spring to uphold the reciprocating element and fold the links; a rod mounted under the table above the bridge adapted to be reciprocated endwise to force the joint or pivot of the links to each other toward the line of the other two pivots of said links.

14. In a pedestal extension-table in combination with the separable parts and pedestal parts pertaining thereto, respectively; an element mounted so as to be inclosed in the pedestal and to reciprocate vertically; a pair of links pivoted to the said element at the lower part; brackets on the pedestal parts respectively at a substantial distance below the table-top arranged to be encountered by the free ends of the links in the endwise movement of the reciprocating element and to guide them laterally after such encounter said brackets being provided with means for becoming engaged each with the link whose said movement is toward the opposite pedestal part; a pair of links pivoted together one of them being pivoted to the reciprocating element and the other to a pivot fixed with respect to the support of said reciprocating element substantially in line therewith; a spring to uphold the reciprocating element and fold the links, and a shaft or rod mounted on one part of the table, adapted to be reciprocated in its bearings, having a lateral fork for engaging the joint or pivot of the two links to each other and adapted to be rocked in its bearings to engage and disengage the fork.

707,187. ROTARY BAKE-OVEN. FRANK H. VAN HOUTEN, Fishkill-on-the-Hudson, N. Y., assignor to Dutchess Tool Company, Fishkill-on-the-Hudson, N. Y., a Corporation of New York. Filed Oct. 10, 1901. Serial No. 78,233. (No model.)

Claim.—1. In an oven, the combination with the circular bake-chamber having top and bottom walls inclined in one direction, a circular flue beneath the bottom wall, a circular chamber above the top wall, an uptake connecting the highest point in said flue and chamber respectively, a stack leading from the lowest point in the circular chamber and a fire-box located at the lowest point in the circular flue, of a central support around which said circular flue passes and an inclined circular rotary hearth mounted on said support in the bake-chamber, the inclination of said hearth being substantially coincident with the inclination of the top and bottom walls of the bake-chamber and means for rotating said hearth extending out through the walls of the oven; substantially as described.



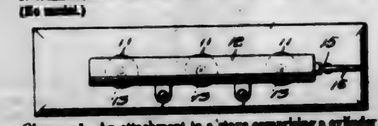
2. In a bake-oven, the combination with an inclined flat rotary hearth mounted on a central support to rotate in an inclined plane, of an inclined circular flue underlying said hearth, a circular chamber overlying said hearth, an uptake connecting said flue and chamber and a valved exit leading from said chamber to the smoke-stack; substantially as described.

3. A bake-oven embodying the following construction, to wit, a circular exterior wall, a central circular bake-chamber formed by inclined top and bottom walls, said bottom wall constituting an arch for an inclined flue and said top wall constituting the floor of an inclined unobstructed chamber overlying the bake-chamber, a top wall for said overlying chamber, an uptake connecting the highest point in the inclined flue and overlying chamber respectively, a fire-box at the lowest point in the flue, a smoke-exit at the lowest point in the overlying chamber, a flat rotary hearth mounted on inclined bearings in the bake-chamber and an entrance-door to said bake-chamber located at the lower front side thereof; substantially as described.

4. In an oven, the combination with the oven-wall having a circular bake-chamber within the same, a circular flue arranged beneath said chamber, a fire-box at one side of said circular flue, an uptake at the opposite side thereof, a circular chamber overlying the circular bake-chamber and with which said uptake communicates and a smoke-stack communicating with said circular chamber at a point opposite the uptake, an inclined circular rotary hearth mounted in the bake-chamber and means for rotating said hearth extending through the wall of the oven; substantially as described.

5. In a bake-oven, a flat rotary hearth formed with a central hub having a bearing-flange and a central cylindrical portion provided with apertures, I-beams passing through said apertures, a flange on the inside of the hub, plates overlying the inner ends of the beams, bolts passing between the beams through the plates and flange on the inside of the hub, and shoe mounted on the beams; substantially as described.

707,188. FORCE-DRAFT ATTACHMENT FOR STOVES. SAMUEL J. WALKER, Louisville, La. Filed Apr. 26, 1902. Serial No. 104,680. (No model.)



Claim.—1. An attachment to a stove comprising a cylinder having one or more outlets in alinement with the draft-apertures, a piston movably disposed within said cylinder, and means whereby air is admitted to the cylinder during the movement of the piston in one direction and dis-

charged from said outlets when said piston is moved in the opposite direction, substantially as described.

2. An attachment to a stove comprising a cylinder having one or more outlets communicating with the draft-chamber, a piston movably disposed within said cylinder, and means whereby air is admitted to the cylinder during the movement of the piston in one direction and discharged from said outlets when said piston is moved in the opposite direction, substantially as described.

3. The combination with a stove having draft-apertures, of a cylinder with lateral outlets in alinement with said apertures, a piston movably disposed within said cylinder, and means for operating said piston, substantially as described.

707,189. FIFTH-WHEEL. JOHN WATTS, Akron, Ohio. Filed Mar. 29, 1902. Serial No. 100,508. (No model.)

Claim.—1. An improved fifth-wheel less than a circle, the lower half of which has a round ball-channel open at the top less in width than the greatest diameter of the channel, one end of said channel being closed by an integral stop, and the other by a detachable plug, substantially as shown and described.

2. An improved fifth-wheel, less than a circle, the lower half of which has a round ball-channel open at the top, the top opening being less in width than the greatest diameter of the channel, said channels being closed at one end with a detachable plug, with balls fitted to run in said lower half and project above its top, and an upper half concentric with the lower, having a flat under face to ride on said balls, and having flanges to overhang the edges of the lower half, substantially as shown and described.

707,190. CARBURETING-LAMP. GEORGE WEDDERBURN, Dunn Loring, Va. Filed Nov. 2, 1901. Serial No. 81,542. (No model.)

Claim.—1. A lamp embodying a fluid-receptacle, a tube leading therefrom to the point of ignition, a globe closed at its lower end, a burner in said globe, and means for generating gas by the exhaustion of the air in the globe by the ignition of the burner and drawing the same upward from the generator to the point of ignition.

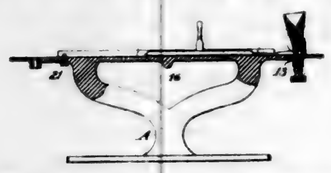
2. A lamp embodying a fluid-receptacle, a tube leading therefrom to the point of ignition, a globe inclosing the upper end of said tube and closed at all points except its upper end, a flue leading from the upper portion of the globe, and means for generating gas by exhaustion created in the globe when the lamp is ignited.

3. A lamp embodying a fluid-receptacle below the point of ignition, a tube leading therefrom to the point of ignition, a globe inclosing the upper end of the said tube, means for creating an exhaustion in said globe when the lamp is ignited and for drawing the generated gas upward through said tube to the point of ignition within the globe.

4. A lamp comprising a fluid-receptacle located at a point below the point of ignition, a globe, a tube leading from the said receptacle and terminating within said globe, and means for drawing air into said receptacle over the fluid therein and up through the said tube and into the globe upon the ignition of the lamp.

5. A lamp comprising a fluid-receptacle below the point of ignition, a globe above said receptacle, a tube leading from the receptacle to the globe, means for admitting air to the receptacle over the surface of the fluid therein to evaporate the latter, means for generating gas by exhaustion created in the globe when the lamp is ignited, a tube leading from the top of the globe, and a mantle over the upper end of the first-mentioned tube within the globe.

707,191. NEEDLE-THREADER. ONORATO A. AICARDI, San Francisco, Cal. Filed Apr. 14, 1902. Serial No. 102,758. (No model.)



Claim.—1. In a device of the character described, the combination of a stand, a horizontal guide-bar provided with a socket for the eye end of the needle, a carrier reciprocable on said guide-bar, a barbed threader-point on said carrier and means in connection with said bar by which a needle may be held at an angle to, but in a vertical plane with, the threader-point, to automatically present its eye to said threader.

2. In a threading device, the combination of a horizontal guide-bar provided with a socket for the eye end of the needle, a carrier reciprocable on said guide-bar, a barbed threader on said carrier, a needle-holder disposed in the path of said threader, said holder arranged at an angle to, but in a vertical plane with, the threader-point, for centering the needle.

3. The combination in a threading device, of a guide-bar, a carrier slidable thereon, a threader-point on said carrier, a guide means for holding a needle in the path of said threader and means for lateral adjustment of said needle-holder.

4. In a threading device, the combination of a guide-bar, a carrier slidable thereon, a barbed threader-point on said carrier, a needle-holder on said bar, and means by which the eye of the needle will automatically position itself in the holder and always present itself in the path of the threader.

5. The combination in a threading device, of a guide-bar, a carrier slidable thereon, a threader-point on said carrier, a needle-holder, said needle-holder having a perforation adapted to receive the needle and means by which the needle may be raised or lowered to bring the eye of the needle into the path of the threader.

6. The combination in a threading device of a guide-bar, a carrier slidable thereon, a threader-point on said carrier, a needle-holder disposed in the path of said carrier and having a transverse adjustment on said guide-bar, means by which the vertical adjustment of the needle is effected, and means by which the needle is made to turn automatically to present its eye in the path of said threader-point.

7. The combination in a threading device, of a guide-bar provided with an adjustable socket to receive the eye end of the needle, a carrier slidable on said guide-bar, a threader-point on said carrier and a needle-holder adapted to hold a needle at an incline in relation to the line of movement of said threader but in the same vertical plane therewith.

8. The combination in a threading device, of a guide-bar, a threader reciprocable thereon, a needle-holder disposed in the path of said threader, said holder having an inclined perforation adapted to receive and hold the needle whereby the needle is made always to present its eye to the threader and cutting means upon the holder for severing the thread.

9. The combination in a threading device, of a support, a horizontal guide-bar vertically adjustable thereon, a reciprocable threader on said bar, a needle-holder, lateral and vertical adjusting mechanism whereby a needle is centered in said holder in relation to the threader and a spool-holding means on said support.

707,192. TROUSERS-SUPPORTER. JOSEPH D. AIKEN, Taftville, Conn. Filed May 13, 1901. Serial No. 59,908. (No model.)

Claim.—In a device of the character described, a bracket formed from a sheet-metal blank, said blank comprising horizontally oppositely-arranged wings having alining perforations, and vertical oppositely-arranged ears, said wings being bent to form parallel supporting-arms and the ears to provide means to secure the bracket to a support, and spring-metal arms projected through the perforations in the wings and projecting on either side thereof and having their opposite ends bent upwardly to form trousers-supporting members.

707,193. BOTTLE-STOPPER. JAMES J. ALLISON, Rockhills, Ill. Filed Nov. 21, 1901. Serial No. 83,100. (No model.)

Claim.—1. In a stopper for bottles, the combination, with such bottle, of an elastic cork, adapted to be secured in the neck of the bottle; a tube, extending lengthwise of the cork, providing means of discharge for the contents of the bottle; a valve at the inner end of said tube adapted to prevent discharge of said contents when said valve is in contact with said cork; means for retaining such valve movably against said cork; and a wedge-shaped plug inserted centrally of the cork, and adapted to force such cork against the inner face of the neck of the bottle, and also prevent friction of such cork upon said tube for the greater part of the length of said cork; substantially as shown and set forth.

2. In a stopper for bottles the combination with such bottles of an elastic cork, adapted to be secured in the neck of the bottle; a tube extending lengthwise of the cork providing means of discharge for the contents of the bottle; a valve at the inner end of said tube adapted to prevent discharge of such contents when said valve is in contact with said cork; means for retaining such valve movably against such cork; a wedge-shaped plug inserted centrally of the cork and adapted to force such cork against the inner face of the neck of the bottle, and also prevent friction of such cork upon said tube for the greater part of the length of said cork; and an annular recess in the inner face of the neck of such bottle substantially as described.

707,194. ELECTRIC RHEOSTAT OR HEATER. HENRY P. BALL, Brooklyn, N. Y., assignor, by mesne assignments, to H. Ward Leonard, Bronxville, N. Y. Filed Nov. 2, 1898. Serial No. 610,796. (No model.)

Claim.—1. In an electric rheostat or heater, the combination of a metallic support comprising two plates having irregular outer surfaces and grooved inner surfaces, a layer of insulating material in said grooves, and a separate resistance-step in each groove, and an edge of one plate projecting beyond the other to expose the ends of the resistances.

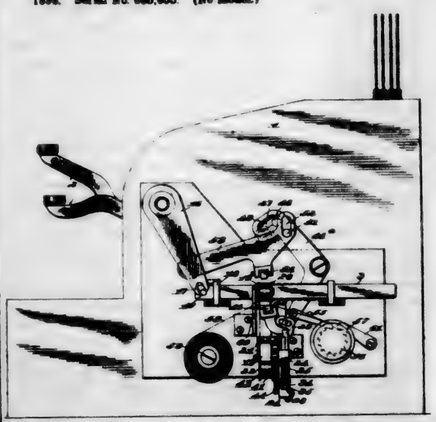
2. In an electric rheostat or heater, the combination of a metallic support comprising two plates having irregular outer surfaces and grooved inner surfaces, a layer of insulating material in said grooves, a separate resistance-step in each groove, and an edge of one plate projecting beyond the other to expose the ends of the resistances, and a series of binding-posts mounted on the projecting edge and to which the resistance-steps are secured.

3. A rheostat or electric heater having a series of resistances, two similar, thin sheets of metal to inclose the resistances in close proximity thereto, thin insulating material applied to the opposing faces of said sheets, and means to secure said sheets together face to face with the edge of each projecting beyond the edge of the other to expose the ends of the resistances.

4. In an electric rheostat or heater, the combination of two metallic plates having a series of grooves or corrugations, a layer of insulating material on the inner sides thereof, a separate resistance-step in each groove, said plates having the ends projecting beyond each other so as to expose the ends of the resistances, and binding-posts for said resistances at the projecting ends of the plates.

5. In an electric rheostat or heater, the combination of two metallic plates having a series of grooves or corrugations, a layer of insulating material on the inner sides thereof, a separate coiled resistance-step in each groove, said plates having the ends projecting beyond each other so as to expose the ends of the resistances, and binding-posts for said resistances at the projecting ends of the plates.

707,195. CASH-REGISTER. FAYETTE B. BARNARD, Dayton, Ohio, assignor, by mesne assignments, to National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed July 11, 1898. Serial No. 685,655. (No model.)



Claim.—1. In a cash-register, the combination with a recording mechanism, of a series of operating-keys, a plurality of graduated plates mounted independently of the keys but so as to be engaged by the same, means connecting the plates to the recording mechanism, and a locking means for said plates for preventing any movement of the same until after the initial movement of a key.

2. In a cash-register, the combination with a recording mechanism, of a series of operating-keys arranged in banks, cam-plates also arranged in banks and connected to said mechanism and arranged to be engaged by said keys, and an independent locking device for each bank of plates for preventing any movement of the latter until a key in the respective bank is operated.

3. In a cash-register, the combination with a recording mechanism, of a series of operating-keys arranged in banks, operating devices connected to the recording mechanism and adapted to be engaged by said keys, a pivoted yoke for each bank of keys and arranged to be operated by said keys and a locking means mounted on each yoke and adapted to

engage its respective operating device to lock the latter until a key has been operated.

4. In a cash-register, the combination with a printing mechanism, of an inking-ribbon, winding-reels for said ribbon, devices connected to said ribbon and pivoted on said reels and arranged to be positively moved by the ribbon and feeding means for said ribbon adapted to be shifted by said pivoted devices to reverse the feed.

5. In a cash-register, the combination with a printing device, of an inking-ribbon, winding-reels for said ribbon, a slide carrying operating means for said reels and means connecting the ribbon to the reels for automatically and positively moving the slide to shift the direction of movement of the ribbon.

6. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels for the same, a slide carrying retaining-pawls and means connecting the ribbon to the reels for automatically and positively moving said slide to reverse the feed when the ribbon is exhausted from one or the other reel.

7. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels for the opposite ends of the same, levers mounted on said reels and connected to said ribbon, a winding device for said reels and means arranged to be operated by said reel-levers to shift the winding devices.

8. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels therefor, a slide, operating-pawls for said reels carried by said slide, locking-pawls for said reels and means mounted on the reels and connected to the ribbon for automatically moving said slide to reverse the feed of the ribbon when the ribbon has become exhausted and its tension is exerted on said means.

9. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels for the same, an operating-slide for said reels and a shifting slide mounted on the operating-slide and arranged to be automatically shifted to reverse the feed.

10. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels for the same, movable devices connecting the ribbon to the reels, an operating-slide and means arranged to be struck by the movable devices for shifting said slide to reverse the feed.

11. In a feeding device for inking-ribbons, the combination with a ribbon, of winding-reels for the same, an operating-slide, means mounted on the reels and connected to the ribbon for shifting the slide to reverse the feed, and a latching device for holding said slide in its adjusted positions.

12. In a cash-register the combination with a recording mechanism, of a series of graduated cams for operating said mechanism, a series of keys engaging said cams during their full strokes but moving the same different distances according to the formation of the cams, and a locking means for said cams adapted to be released by the operation of a key.

13. In a cash-register, the combination with a series of keys, of printing devices arranged to be operated by the same, an inking-ribbon, winding-reels for said ribbon, pivoted devices mounted on said reels and connected to said ribbon, and means operated by the printing devices for feeding said ribbon and adapted to be shifted by said pivoted devices to shift the feed.

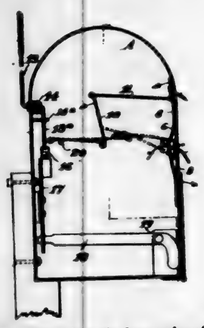
14. In a cash-register the combination with a series of keys, of a movable member common to said keys, printing devices arranged to be set by said keys on their downstrokes, a platen operated by the movable member, an inking-ribbon and a slide connected to the platen and arranged to feed the ribbon as the keys and printing devices move back toward normal position.

707,196. POSTAL BOX AND SIGNAL. FRANCIS C. BATH, San Jose, Cal., assignor to Bates-Hawley Postal Box Signals Company, San Jose, Cal., a Corporation of California. Filed Mar. 31, 1902. Serial No. 100,708. (No model.)

Claim.—1. The combination in a postal box of parallel hinged doors extending along the front, one above the other, a lock for the lower door and springs by which the upper door is normally closed, said upper door being opened for the reception of mail by pushing it inwardly against the spring-pressure, and a table pivoted parallel with the hinged edge of the upper door and means connecting its free edge with the free edge of said door, said table serving as a guard to close the opening behind the door, and being actuated in unison with said door to receive the mail and deposit it in the lower part of the box when the door is closed.

2. A mail-box having a door closing the upper part of the front and hinged at the lower edge; springs by which said door is normally closed; a table pivoted at the lower edge within and parallel with the door and with its axis approximately in line horizontally at the rear of the door-hinge; and connections between the free edges of the door and table whereby the latter moves in unison with and in the same direction with the door, and forms a tubular receiving-surface substantially in line with the door when the latter is opened.

3. A postal box having a door opening into the upper part of one side, said door having the lower edge horizontally hinged, springs by which the upper edge is normally closed from the inside, a table having its lower edge pivoted within the box parallel with and behind the door-hinges and approximately in line horizontally therewith, links connecting the movable edges of the door and table whereby the table forms substantially a horizontal continuation thereof and moves in unison and in the same direction with the door so that when the door is opened the table serves to receive anything introduced and to discharge it into the lower part of the box when the door closes, and the table resumes its normal position.



4. A postal box having a door, the lower edge of which is horizontally hinged approximately central of one side of the box, springs by which said door is normally closed outwardly against the box-front, a receiving-table and guard consisting of a plate, the lower edge of which is pivoted parallel with the hinged edge of the door, links connecting the movable edges of the door and the table whereby the latter is forced downwardly and backwardly to form a guard and close the opening behind the door when the latter is opened, said table being moved into its normal inclined position when the door is closed.

5. A postal box having parallel admission and discharge doors, the lower edges of which are hinged one above the other horizontally across the front of the box, a guard-plate and table pivoted parallel with the hinged edge of the upper door, and in the same direction, said plate forming substantially a horizontal continuation of the upper door when the latter is open, links and springs by which the two are movable in unison and approximately in line horizontally with said hinged edge of the door, a signal-carrying arm journaled in the side of the box having the inner end extending into the line of travel of the table edge whereby the signal is thrown up into view when the receiving-door is opened, and a spring-latch by which the signal is retained in exposed position after the door is closed.

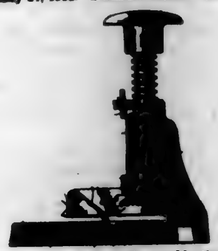
6. A postal box having superposed parallel doors hinged horizontally along the front by their lower edges, a hinged swinging guard and table connected with and actuated by the opening of the upper door, and movable in the same direction with the door, and forming substantially a horizontal continuation thereof when the door is opened; a signal-carrying arm journaled in the side of the box having the interior end projecting into the path of travel of the movable table whereby the signal is raised into an exposed position when the admission-door is opened, a spring-latch, a vertically-movable slide upon which it is carried, said latch engaging the arm and holding the signal exposed after the admission-door is closed and a falcrumed lever having one end engaging the slide and the opposite end connected with the lower door whereby the signal is released and allowed to fall into a concealed position by the opening of said door.

7. A postal box having parallel doors one above the other hinged by their lower edges, the lower door opening outwardly about its hinges and normally secured by a lock, the upper door opening inwardly about its hinges, springs by which said upper door is normally closed against the front of the box a swinging guard-table pivoted parallel with and interior to the admission-door, links by which the two are connected to swing in unison, a signal-carrying arm exterior to the box journaled therein having an interior arm, an arm carried by the swinging table adapted to engage the interior portion of the signal-carrying arm when the admission-door is opened whereby the signal is thrown up into view, a vertically-guided slidable bar, a spring-latch carried thereby, a bell-crank lever, the long arm of which engages said slide and the short arm is engaged by the lower door when the latter is closed whereby the slide and the spring are thrown upward so as to engage the signal-arm and retain the signal exposed after the admission-door is closed, said bell-crank lever and slide falling by gravitation when the lower door is opened to release the lever and allow the signal to drop and disappear.

707,197. SASH-WEIGHT. GILES A. BURGWIN, Waterford, and CHARLES L. LAMPHERE, Berwick, Conn. Filed Oct. 28, 1901. Serial No. 79,530. (No model.)

Claim.—A sash-weight having one end hooked and slotted vertically at its upper end and having also side slots, and a pulley having oppositely-extending axial projections engaging in the said side slots, the pulley-body being disposed in the slot at the end of the hook all substantially as shown and described.

707,198. STAMP-AFFIXER. EDGAR A. ROBINSON, St. Louis, Mo. Filed May 27, 1901. Serial No. 62,603. (No model.)



Claim.—1. In a stamp-affixer, the combination with a support for the article to be stamped, of an overhanging frame, a pivoted wiper mounted in said frame, and depending toward the supporting-surface for the article to be stamped, whereby said article can pass between said frame and said wiper, and a bar with which said wiper coöperates to force said wiper upon the article to be wiped; substantially as described.

2. In a stamp-affixer, the combination with a support for the article to be stamped, a flange arranged upon the side of said support, an overhanging frame, a guiding-lodge on said frame and above said flange, a pivoted wiper mounted in said overhanging frame and depending toward the supporting-surface for the article to be stamped, whereby said article can pass between said surface and said wiper, and a bar $a^{\prime}$ for coöperating with the wiper to force said wiper upon the article to be wiped; substantially as described.

3. In a stamp-affixer, the combination with a support for the article to be stamped, of a plunger for affixing the stamp, a recovering-spring for said plunger, and a pilot-plunger projecting beneath the main plunger immediately above the stamp to be affixed when said stamp is in position to be affixed; substantially as described.

4. In a stamp-affixer, the combination with a support for the article to be stamped, of a stamp-affixing plunger, means exerting pressure against said plunger to hold it constantly in an elevated position, a pilot-plunger telescopically mounted in the lower end of said first-mentioned plunger and arranged within the area of the lower face of said stamp-affixing plunger, and means coöperating with said pilot-plunger tending to hold the same constantly in a lowered position; substantially as described.

5. In a stamp-affixer, the combination with a support for the article to be stamped, of a plunger provided with a head on its lower end designed to cover the stamp to be affixed, a spring for holding said plunger in an elevated position above the support, a pilot-plunger projecting through said head, which head is recessed on its under side to receive the pilot-plunger, and a spring for holding said pilot-plunger in a lowered position; substantially as described.

6. In a stamp-affixer, the combination with a support for the article to be stamped, of a way for receiving a strip of stamps, said way being located on a plane above the support for the article to be stamped so as to form a shoulder a^{10}, a vibrating plate mounted to travel in said way, a group of pawls mounted on said vibrating plate, a main plunger for severing or severing the stamp at the shoulder a^{10}, a pilot-plunger for holding the stamp upon the article to be stamped while the main plunger is operating on the stamps, and a connection between said main plunger and the vibrating plate; substantially as described.

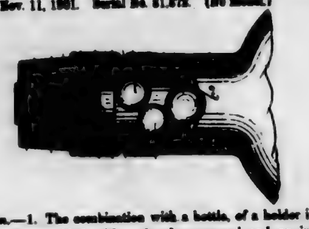
7. In a stamp-affixer, the combination with a main plunger, of a presser-frame yieldingly mounted thereon and normally located on a lower plane than the face of the main plunger, and a pilot-plunger; substantially as described.

8. In a stamp-affixer, the combination with a main plunger, of a way for a strip of stamps, a shoulder a^{10} over which the stamps are advanced in the path of the main plunger, a pilot-plunger mounted in the main plunger for holding the stamps in position while said stamps are being operated upon by the main plunger, means for advancing the stamps in the paths of the main and pilot plunger, and a yielding presser-frame mounted on the main plunger for engaging the adjacent stamp before the main plunger severs the stamp to be affixed, substantially as described.

9. In a stamp-affixer, the combination with a support for the article to be stamped, of a moistening device, a way for receiving a strip of stamps, said way terminating at a shoulder a^{10}, means for advancing the stamps over said shoulder, a plunger operating in juxtaposition to the shoulder, a pilot-plunger for engaging the stamp to be affixed and forcing it onto the article to be stamped, and a presser-frame for engaging the adjacent stamp and holding it while the plunger severs the stamp to be affixed from its companions; substantially as described

---

707,199. NON-REFILLABLE BOTTLE. SAMUEL D. BLOCKER, Columbus, Ohio, assignor of one-half to William J. Greene, Columbus, Ohio. Filed Nov. 11, 1901. Serial No. 81,672. (No model.)



Claim.—1. The combination with a bottle, of a holder in the neck thereof, a tube provided with a closed upper end and an intermediate opening, said tube being adjustably fitted in the holder and the holder being capable of inclosing said opening, and a cap fastened to the upper end of the tube and inclosing the major part of the tube, said cap extending downward and being movable with the tube into and out of engagement with the upper end of the neck of the bottle.

2. The combination with a bottle, of a holder in the neck thereof, and a tube with a closed upper end and an intermediate opening, said tube being adjustably fitted in the holder and the holder being capable of closing the said opening, a spout projecting upward from the neck of the bottle and surrounding the tube, and a cap fastened to the tube and inclosing the spout, for the purpose specified.

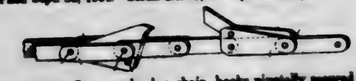
3. The combination with a bottle, of a cup set into the neck thereof and having a contraction at its upper end forming a holder, the cup also having an opening in its bottom, a tube set in the holder, said tube being closed at its upper end and having an opening intermediate its ends, a spring-actuated means in the tube for commanding the liquid flow through the opening, and a weight in the cup, said weight normally closing the opening in the bottom of the cup and being capable of rolling into the tube to actuate said spring-actuated means therein.

4. The combination with a bottle, of a holder in the neck thereof, a tube having a closed upper end and an opening intermediate its ends said tube being adjustably fitted in the holder and the holder being capable of closing said opening, a spring-actuated valve in the tube, and a weight arranged below the valve and capable of entering the tube to open the valve.

5. The combination with a bottle, of a holder in the neck thereof, and a tube with a closed upper end and an intermediate opening, said tube being adjustably fitted in the holder and the holder being capable of closing the said opening, a spout projecting outward from the neck of the bottle and surrounding the tube, a cap fastened to the tube and inclosing the spout, for the purpose specified, a valve arranged in the tube, and a weight located below the valve and capable of entering the tube to open the valve.

6. The combination with a bottle, of a cup set into the neck thereof and having a contraction at its upper part forming a holder, the cup also having an opening in its bottom, a tube located adjustably in the holder, the tube having a closed upper end and an intermediate opening, a valve arranged in the tube, and a weight carried in the cup and capable of entering the tube to open the valve.

707,200. CAR-HAUL. SIDNEY W. BOLLINGER, Pittsburg, Pa. Filed Sept. 20, 1901. Serial No. 75,917. (No model.)



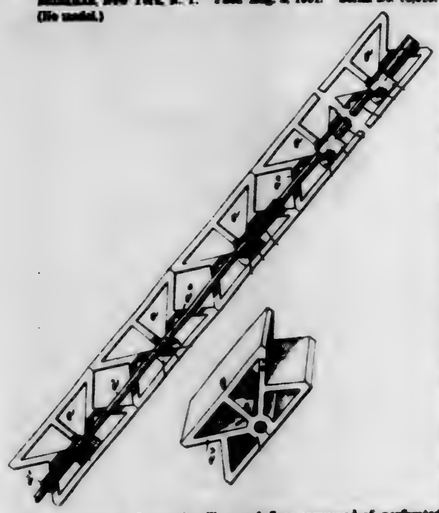
Claim.—1. In a car-haul, a chain, hooks pivotally secured thereto and arranged so that alternate hooks engage a step on a car in opposite directions.

2. In a car-haul, a chain-support, a slot in said support, a chain, a hook pivotally secured to said chain and a second chain-support, said chain-supports and said slot providing means for lowering and raising the end of said hook.

3. In a car-haul chain, a hook pivotally secured at one end to the link of said chain, a slot in said hook and a pin through said slot and secured to said link.

4. In a car-haul, a car having a step, a chain, a hook pivotally secured thereto and means for raising the hook independent of the chain so as to engage the step on said car.

707,201. FIREPROOF CEILING AND FLOOR. SEBASTIAN G. BUTSKRAM, New York, N. Y. Filed Aug. 2, 1901. Serial No. 70,613. (No model.)



Claim.—1. A fireproof ceiling and floor composed of perforated blocks arranged in rows, longitudinal rods engaging the perforated blocks, means for locking the rods to the blocks, and transverse braces at right angles to the rods, substantially as specified.

2. A fireproof ceiling and floor composed of perforated blocks arranged in rows, longitudinal rods engaging the perforated blocks, hooks engaging the longitudinal rods, and transverse rods between the hooks, substantially as specified.

3. A fireproof ceiling and floor composed of perforated blocks arranged in rows, longitudinal rods engaging the perforated blocks, hooks engaging the rods, transverse rods engaging the hooks and blocks, and couplings for forcing the hooks against the longitudinal rods, substantially as specified.

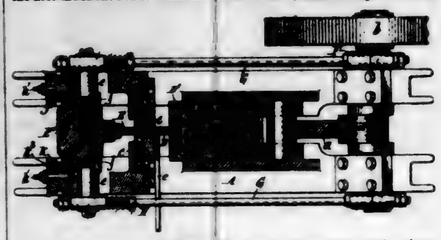
4. A fireproof ceiling and floor composed of blocks provided with perforations and grooves arranged at right angles to each other, longitudinal rods engaging the perforations, and transverse rods engaging the grooves, substantially as specified.

5. In a fireproof ceiling or floor, a block composed of a top plate, a bottom plate, an intervening perforated hub, and diagonal braces that extend in the same direction as such hub, combined with a rod passing through the perforated hub, and means for supporting the ends of the rod, substantially as specified.

707,202. MECHANICAL MOVEMENT FOR NUT-MAKING OR OTHER MACHINERY. OSCAR C. BERRY and BERTRAM C. GARDNER, Buffalo, N. Y.; said Gardner assignor to said Berry. Filed Nov. 1, 1902. Serial No. 30,112. (No model.)

Claim.—1. The combination of a slide, actuating mechanism for said slide including a lost-motion connection, a stop for arresting said slide before said actuating mechanism thereafter reaches the end of its stroke, a second slide, parts carried by said slides and arranged one in advance of the other in a plane parallel to the direction of movement of said slides, and means for reciprocating said second slide, whereby the part carried thereby approaches the part carried by said first slide while the latter is at rest, substantially as set forth.

2. The combination of two slides arranged one in advance of the other in substantially the same plane, actuating mechanism for one of said slides including a lost-motion connection, a stop for arresting said slide before said actuating mechanism thereafter reaches the end of its stroke, and means for reciprocating said second slide whereby the same approaches the first-mentioned slide while the latter is at rest, substantially as set forth.

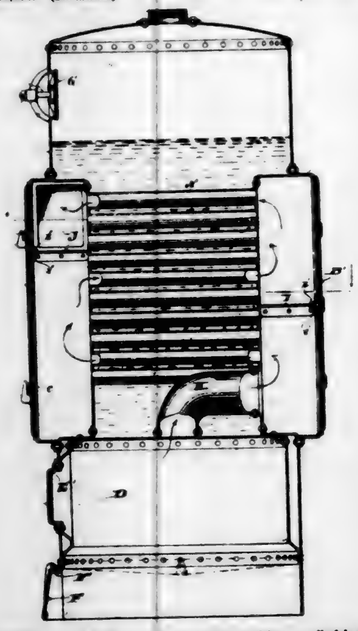


3. The combination of two slides mounted to reciprocate in substantially the same plane and arranged one in advance of the other, actuating mechanism for the front slide including a lost-motion connection, a stop for arresting said first slide before said actuating mechanism thereafter reaches the end of its stroke, and means for reciprocating said rear slide whereby the same approaches the front slide while the latter is at rest, substantially as set forth.

4. The combination of a slide, a rotary shaft, operating connections between said slide and said rotary shaft including a lost-motion device, a second slide, operative connections between said second slide and said shaft, parts carried by said slides and arranged one in advance of the other in a plane parallel to the direction of movement of the slides, and a stop for arresting said first-mentioned slide before said second-mentioned slide reaches the end of its stroke, substantially as set forth.

5. The combination with a slide, of rotary eccentrics, pitmen connected to said eccentrics and loosely connected to said slide, shoulders on said pitmen, springs interposed between said shoulders and said slide at one side, shoulders on said pitmen at the other side of said slide, and a stop adapted to arrest the movement of said slide before said eccentrics reach the end of their stroke, substantially as set forth.

707,203. BOILER OR WATER-HEATER. DAVID M. BURNS and ALEXANDER B. BURNS, Greenbay, Wis. Filed May 5, 1902. Serial No. 105,902. (No model.)



Claim.—1. A boiler or water-heater comprising a cylindrical shell, boxes extending into the shell and provided with outer doors, flues in tiers connecting the boxes, a baffle-plate dividing one of the boxes into approximately equal upper and lower compartments, a similar plate in the other box at a greater elevation than the plate aforesaid, the minor upper compartment of the latter box being open at one end for communication with a smoke-stack, a fire-chamber of less diameter than said shell built therein central of same, and pipes, leading from the fire-chamber into the lower compartment of the box aforesaid.

2. A boiler or water-heater comprising a cylindrical shell, boxes extending into the shell and provided with outer doors, flues in tiers connecting the boxes, a baffle-plate dividing one of the boxes into approximately equal upper and lower compartments, a similar plate in the other box at a greater elevation than the plate aforesaid, the minor upper compartment of the latter box being open at one end for communication with a smoke-stack, flanges on the box-doors arranged to lap the baffle-plates, a fire-chamber of less diameter than said shell built therein central of same, and pipes leading from the fire-chamber into the lower compartment of the first aforesaid box.

707,204. RECORDER FOR PHONOGRAPHS, &c. HUBERT V. BUTTERWORTH, Newark, N. J. Filed Mar. 25, 1901. Serial No. 52,696. (No model.)

Claim.—1. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment pivotally arranged and secured within said tubular member, having its recording-diaphragm extending beyond said tube-plate, and an adjusting-screw in the tubular member of said tube-plate in engagement with a portion of said pivotally-arranged recording attachment for the angular adjustment of the diaphragm of said recording attachment, relative to the surface of the phonograph-cylinder, substantially as and for the purposes set forth.

2. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment arranged and secured within said tubular member, having its recording-diaphragm extending beyond said tube-plate, and an adjusting-screw 14 arranged in said tubular member and in supporting engagement with a portion of said recording attachment for the angular adjustment of the recording-diaphragm relative to the surface of the phonograph-cylinder, substantially as and for the purposes set forth.

3. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment arranged and secured within said tubular member, having its recording-diaphragm extending beyond said tube-plate, and an adjusting-screw in said tubular member having its point in supporting engagement with a portion of said recording attachment, substantially as and for the purposes set forth.

4. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment within said tubular member, having its recording-diaphragm extending beyond said tube-plate, and means connected with and within the said tubular member for securing said recording attachment in oscillatory relation within said tubular member, substantially as and for the purposes set forth.

5. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment within said tubular member, having its recording-diaphragm extending beyond said tube-plate, and means connected with and within the said tubular member for securing said recording attachment in oscillatory relation within said tubular member, consisting, of a pair of pivots arranged in the opposite sides of said tubular member, and having their inner ends in pivotal supporting engagement with said recording attachment, substantially as and for the purposes set forth.

6. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment within said tubular member, having its recording-diaphragm extending beyond said tube-plate, means connected with said tubular member for securing said recording attachment in oscillatory relation within said tubular member, and an adjusting-screw in said tubular member, having its point in supporting engagement with a portion of said recording attachment, substantially as and for the purposes set forth.

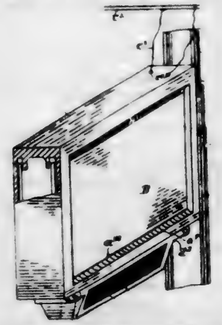
7. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment within said tubular member, having its recording-diaphragm extending beyond said tube-plate, means connected with said tubular member for securing said recording attachment in oscillatory relation within said tubular member, consisting, of a pair of pivots arranged in the opposite sides of said tubular member, and having their inner ends in pivotal supporting engagement with said recording attachment, and an adjusting-screw in said tubular member, having its point in supporting engagement with a portion of said recording attachment, substantially as and for the purposes set forth.

8. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment, consisting, of a tube 10, having a ball-shaped end, arranged within said tubular member, and means in said tubular member and in engagement with said ball-shaped end for the oscillatory arrangement of said tube 10 within said tubular member, and a recording-diaphragm on the opposite end of said tube 10, substantially as and for the purposes set forth.

9. In a recorder for phonographs or the like, the combination, with a tube-plate and its tubular member, of a recording attachment, consisting, of a tube 10, having a ball-shaped end, arranged within said tubular member, means in said tubular member in engagement with said ball-shaped end for the oscillatory arrangement of said tube 10 within said tubular member, a recording-diaphragm on the opposite end of said tube 10, and an adjusting-screw in said tubular member, having its point in supporting engagement with a portion of said tube 10, substantially as and for the purposes set forth.

10. In a phonograph, the combination, with a record-receiving cylinder and the frame in which the recorder is arranged, of a recording attachment comprising a tube-plate secured to said frame, a tubular member connected with said tube-plate, a second tubular member pivotally connected with the tubular member of said tube-plate, said second tubular member having its opposite end extending beyond the said tube-plate, a recording-diaphragm on the free end of said second tubular member, and a stylus on said recording-diaphragm, the said stylus, the recording-diaphragm and said second tubular member, all being arranged in such relation to the cylindrical surface of the record-receiving cylinder, that an imaginary plane through the point of pivotal support of said second tubular member and the point of contact of the stylus with the cylindrical surface of the recording-cylinder will produce a cosine with the recording-cylinder, substantially as and for the purposes set forth.

707,205. ADVERTISING DEVICE. WILLIAM D. BUTT, Kansas City, Mo. Filed July 23, 1901. Serial No. 69,251. (No model.)



Claim.—1. An advertising frame or case having a longitudinal opening in the bottom thereof and transparent sides, a luminous body within said case and an auxiliary box removably secured to the under surface of the bottom of said case.

2. An advertising-case having a longitudinal opening in the bottom thereof, a luminous body within said case, and an auxiliary box hinged at one end to the under surface of the bottom of said case and securing devices upon said frame and box for the other end of said box.

3. In an advertising-frame having removable panels, and an opening in the bottom of said frame for the insertion of said panels, a pendent member of said frame covering said opening, having longitudinal openings in the sides of said pendent member and grooves in the sides of said openings, and openings in one end of said pendent member and removable signs adapted to be inserted through the openings in the end of said pendent member.

707,206. BODY FOR MOTOR-VEHICLES. FERDINAND CHARRON and LÉONCE GIRARDOT, Paris, France. Filed Apr. 22, 1902. Serial No. 104,008. (No model.)

Claim.—1. A body for motor road-vehicles with a back rotunda-

seat arranged at the hook part *c* of the carriage, closed at the sides and at the back, in combination with a front seat or driver's seat *a* one part of which can be lifted sidewise by pivoting on the stationary part, in combination with a door *d* arranged at the side of the movable part of the seat *a*, and in combination with a lever *h* arranged beneath the movable part of the seat and pivoted to a stationary point *o* intermediate of its length and with a bent rod *k* pivoted by one end to the small arm of the lever *h* and by the other end to the door *d*, near the hinge thereof substantially as and for the purpose set forth.

2. A body for motor road-vehicles with a hook-pivoted seat arranged in a part *c* of the carriage, closed at the sides and at the back, in combination with a front seat *a* made of two parts, one stationary and the other movable and pivoted to the stationary part, in combination with a petroleum-reservoir *b* arranged beneath the seat *a* and provided with a vertical recess *i* and a horizontal recess at the under part *l*, in combination with a door *d* arranged at the side of the movable part of the seat *a*, in combination with the lever *h* pivoted at *o* to the wall of the reservoir *b*, located in the recess *i* and carrying at the end of its long arm a roller *j* which bears constantly against the bottom of the movable part of the seat *a* and rolls on the way *s* when the seat is raised or lowered, in combination with a bent rod *k* located in the recess *l* and pivoted by on.. end to the small arm of the lever *h* and by the other end to the inner surface of the door at a certain distance from the hinge, substantially as and for the purpose set forth.

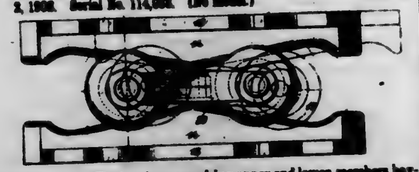
707,207. CAN-OPENER. JAMES GRIMMER, Fort Liscum, Alaska. Filed Jan. 20, 1902. Serial No. 90,282. (No model.)

Claim.—1. A can-opener having a body provided with a curved undercut shoulder, a slotted extension or projection, the cutting-blade adjustably arranged in said slotted extension, and an operating-handle connected to the body, as set forth.

2. A can-opener comprising a body portion having a curved undercut shoulder, an obliquely-slotted extension or projection, a cutting-blade having its shank arranged in said slotted extension, and means arranged within the slot and connected to the shank for the purpose of adjusting the blade, as set forth.

3. A can-opener comprising a body portion having a curved edge and a curved undercut shoulder, the obliquely-slotted extension or projection, the cutting-blade having its shank located in said slot, the adjusting-screw working in the slot and passing through the shank and the operating-handle integral with the body portion, substantially as set forth.

707,208. SIDE-AND CENTER-BEARING FOR CAR-TRUCKS. EDWARD CLIFF, Newark, N. J., assignor to Voss and Cliff Manufacturing Company, New York, N. Y., a Corporation of New York. Filed July 2, 1902. Serial No. 114,023. (No model.)



Claim.—1. The bearing comprising upper and lower members having at each side of a vertical transverse line the oppositely-inclined track-surfaces, combined with the rollers located between said surfaces, and means for keeping said rollers a definite distance apart; substantially as set forth.

2. The bearing comprising upper and lower members having at each side of a vertical transverse line the oppositely-inclined track-surfaces diverging toward the outer ends of the bearing, combined with the rollers located between said surfaces, and means for keeping said rollers a definite distance apart; substantially as set forth.

3. The bearing comprising upper and lower members having at each side of a vertical transverse line the oppositely-inclined track-surfaces, combined with the rollers located between said surfaces, and having the end flanges extending over the edges of said surfaces, and means for keeping said rollers a definite distance apart; substantially as set forth.

4. The bearing comprising the upper and lower members having at each side of a vertical transverse line the oppositely-inclined track-surfaces, combined with the rollers located between said surfaces, and the roller-frame connecting said rollers and having the axles extending into the bores of said rollers; substantially as set forth.

5. The bearing comprising upper and lower members having at each side of a vertical transverse line the oppositely and equally inclined track-surfaces, combined with the rollers located between said surfaces, and means for keeping said rollers a definite distance apart; substantially as set forth.

707,209. TOE-CLIP FOR BICYCLES. GEORGE W. COLE, Asbury Park, N. J., assignor to G. W. Cole Company, a Corporation of New Jersey. Filed Nov. 20, 1901. Serial No. 83,466. (No model.)

Claim.—1. In a toe-clip for bicycles, the combination with a loop formed of wire or other suitable material, a plate uniting the ends of said loop to hold the same in position, tongues bent out from said plate; a strip of leather or other material, one end of which is secured to said plate by said tongues and the other end secured to said loop.

2. In a toe-clip for bicycles, the combination of a loop formed of wire or other suitable material, and provided with a laterally-projecting offset at or about the middle of said loop; a plate uniting the ends of said loop to hold the same in position; tongues bent out from said plate; a strip of leather or other suitable material, one end of which is secured to said plate by said tongues, and the other end secured to said loop.

3. In a toe-clip for bicycles, the combination with a loop formed of wire or other suitable material, and provided with a laterally-projecting offset at or about the middle of said loop, the ends of said wire being bent out of said loop to form part of the fastening means to secure said clip to a pedal; a plate uniting the ends of said loop to hold the same in position, said plate being provided with tongues bent out from said plate; a strip of leather one end of which is secured to the laterally-projecting offset in said loop and the other end secured to said plate by said tongues.

4. In a toe-clip for bicycles, the combination with a loop formed of wire or other suitable material, a clamp consisting of a bolt and nut or other suitable construction for fastening the clip to a pedal, a plate uniting the ends of said loop to hold the same in position, tongues bent out from said plate; a strip of leather or other suitable material, one end of which is secured to the plate by said tongues and the other end secured to said loop.

707,210. FIREPROOF BUILDING. FRED W. COOLEY, Minneapolis, Minn., assignor of two-thirds to George T. Houstain, Minneapolis, Minn. Filed Dec. 13, 1901. Serial No. 86,726. (No model.)

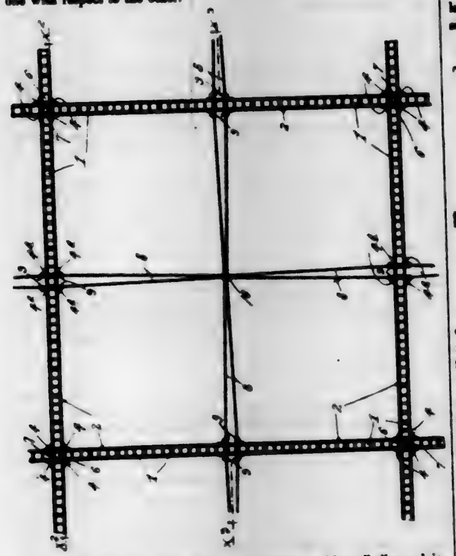
Claim.—1. In a fireproof wall, the combination with tile blocks and interposed metal bars, of anchoring devices locked to said bars and embedded in the cement interposed between said bars and tile blocks.

2. In a fireproof wall, the combination with tile blocks and interposed metal bars, of anchoring devices overlapping the edges of said bars and embedded in the cement interposed between said bars and tile blocks.

3. In a fireproof wall, the combination with tile blocks and interposed metal bars, of the anchoring-hooks 3' embedded in the cement interposed between the said bars and tile blocks and provided with the hooked ends 3* which overlap the edges of said bars.

4. In a fireproof wall, the combination with tile blocks and metal bars laid double and interposed between the layers of tile blocks, of anchoring devices embedded in the cement interposed between said tile blocks and bars and engaging over the edges of said bars to prevent lateral movements of the one bar with respect to the other, substantially as described.

5. In a fireproof wall, the combination with the tile blocks and metal bars laid double and interposed between said layers of tile blocks, of the anchoring-hooks 3 embedded in the cement interposed between said tile blocks and metal bars and provided with hooked ends 3* which engage over the edges of said bars and hold the same against lateral movements, one with respect to the other.



6. In a fireproof structure, the combination with wall-tiles and interposed metal bars which bars overlap at the corners of the bin, of metal columns placed in the corners formed at the junctions of said walls, and devices for tying the said columns together, substantially as described.

7. In a fireproof structure, the combination with wall-tiles and interposed metal bars overlapped at the corners of the bins, of metal angle-columns placed in the corners at the junctions of said walls, and metal tie-straps connecting the opposite angle-columns and with their ends bent to embrace the flanges thereof, substantially as described.

8. In a fireproof structure, the combination with wall-tiles and interposed metal bars overlapped at the corners of the bins, of the angle-iron columns 4 placed in the corners at the junctions of the walls, and the tie-straps 5 connecting the opposite angle-columns and having their ends bent over the flanges thereof, substantially as described.

9. In a fireproof structure, the combination with the wall-tiles 1 and interposed metal bars 2 the latter being overlapped at the corners of the bins, the corner-tiles 6 placed at the corners of the bins, the angle-columns 4 placed in the corners formed by adjoining walls, and the tie-straps 5 embracing said corner-tiles and with their ends bent around the flanges of opposite angle-columns, substantially as described.

10. In a fireproof structure, the combination with wall-tiles of the interposed and overlapped metal bars 2 provided at the corners of the bins with notches 2* and lock-bolts placed within said notches 2* for interlocking the parts, substantially as described.

11. The combination with the walls of a bin or similar structure, of truss-rods or bars arranged in approximately parallel pairs connecting the opposite sides thereof, and means for drawing the central portions of said truss-rods together to tighten the same, substantially as described.

12. The combination with the walls of a rectangular bin or structure made up of tile blocks and interposed metal bars, of intermediate columns reinforcing the walls of said bin and internally-spaced metal bars or rods connecting opposite members of said intermediate columns which tie bars or rods are arranged in pairs and are drawn together at their intermediate portions, substantially as described.

13. The combination with a bin or similar structure, the walls of which are made up of tile blocks and interposed metal bars or beams, of columns applied to the intermediate portions of said interposed bars or beams, and tie bars or rods connecting the opposite or distant intermediate columns.

14. The combination with the walls of a rectangular bin or similar structure made up of layers of tile blocks and interposed metal bars or beams, of intermediate columns arranged in groups of four positioned in pairs on the opposite sides of said interposed bars, and pairs of tie bars or rods connecting opposite pairs of said intermediate columns, substantially as described.

15. The combination in a fireproof wall, of layers of tile blocks and interposed and overlapped metal bars provided with coincident notches, and lock-pins placed in the said coincident notches whereby the said overlapped bars are locked against endwise movements, one upon the other, substantially as described.

707,211. RICE-HULLING MACHINE. JOHN R. CRESWELL, Moline, Ill., assignor to Barnard and Leas Manufacturing Company, Moline, Ill. Filed May 6, 1901. Serial No. 58,886. (No model.)

Claim.—1. The combination of a casing, a longitudinal hulling plate or knife, and a revoluble hulling-cylinder having tapered longitudinal hulling-ribs adapted in conjunction with the knife to effect a shear cut in either direction of revolution of the cylinder.

2. In a rice-huller, the combination of the casing, the hulling plate or knives, and hulling-cylinder provided with longitudinal tapering hulling-ribs adapted in conjunction with said plates to effect a shear cut in either direction, with transversely-disposed baffles within the casing, substantially as described.

3. In a rice-huller, the combination of the casing, the hulling plate or knives therein, the hulling-cylinder having longitudinal tapering hulling-ribs adapted to effect a shear cut in either direction, and force-feed flanges at its feed end, all substantially as described.

4. In a rice-huller, the combination of the casing, the hulling plates or knives therein, the conical hulling-cylinder having longitudinal tapering hulling-ribs adapted to effect a shear cut in either direction, and the removable force-feed-screw casting supporting the smaller end of the cylinder upon the main shaft, all constructed and adapted to operate substantially as described.

5. In a rice-huller, the combination of the casing, the main shaft, and the hulling plates or knives at opposite sides of the casing; with the hulling-cylinder intermediate the knives having longitudinal tapered hulling-ribs adapted to effect a shear cut in either direction, and transversely-disposed baffle-ribs within the casing all adapted to operate substantially as described.

6. In a rice-huller, the combination of the casing, the main shaft, and the hulling plates or knives at opposite sides of the casing, and the conical hulling-cylinder intermediate the knives having longitudinal tapered hulling-ribs adapted to effect a shear cut in either direction; with transversely-disposed baffles above and below the cylinder, and a force-feed screw at the smaller end of the cylinder, all adapted to operate substantially as described.

7. In a rice-huller, the combination of the frame, the arch-bar suspended therefrom, having an internal inwardly-projecting baffle-rib, the screen-plates having their inner ends supported by said bar; the hulling plates or knives, and the hulling-cylinder, substantially as described.

8. In a rice-huller, the combination of the frame, the arch-bar suspended therefrom, having an internal inwardly-projecting baffle-rib, the screen-plates having their inner ends supported by said bar; the hulling plates or knives, and the hulling-cylinder; with the removable force-feed screw on said shaft supporting and interlocked with the adjoining end of the cylinder, substantially as described.

9. In a rice-huller, the combination of the frame, the arch-bar suspended therefrom, having an internal inwardly-projecting baffle-rib, the screen-plates having their inner ends supported by said bar and the upper half of the casing having internally-projecting baffle-ribs; with the hulling plates or knives, the main shaft, the conical hulling-cylinder thereon having longitudinal tapered hulling-ribs, and the removable force-feed screw on said shaft supporting and interlocked with the smaller end of the cone, all constructed and adapted to operate substantially as and for the purpose described.

707,212. SOLDERING-IRON. JAMES C. OWENS, Watervliet, N. Y. Filed Apr. 14, 1902. Serial No. 103,013. (No model.)

Claim.—1. In a soldering-iron, the combination with a holder having separated arms at its ends each formed with penetrating edge flanges on its inner face, said flanges having cross-grooves therein and a bow

formed on the outer face of one of the arms having a threaded interior, a point having a tongue fashioned to fit between the arms and be engaged by the flanges at or near the outer edge of the tongue, and a screw-bolt passing through the arms and tongue having its end seated in the boss; substantially as described.

2. In a soldering-iron, the combination with a holder having separated arms at its end each provided with engaging flanges having a series of cross-grooves the edges of the walls of which constitute teeth therein, a soldering-point having a flat-sided tongue, and means for securing the tongue between the flanges of the arms, substantially as described.

3. In a soldering-iron, the combination with a holder having separated arms at its ends each formed with holding edge flanges on its inner face, and a boss formed on the outer face of one of the arms having a threaded interior, a point having a tongue fashioned to fit between the arms and be engaged by the flanges at or near the outer edge of the tongue, and a screw-bolt passing through the arms and tongue having its end seated in the boss, substantially as described.

4. In a soldering-iron, the combination with a holder having separated arms formed with holding-flanges and a pivot secured between the flanges, of a handpiece into which the end of the shank of the holder fits, and a series of teeth on the opposite edges of the end of the shank having inclined outer and straight upper edges for engaging the handpiece.

707,218. METHOD OF MOLDING SPOKE-WHEELS AND THE PRODUCT THEREOF. GEORGE H. DOCKERSON and JOHN M. GORDON, Columbus, Ind. Filed May 28, 1902. Serial No. 109,265. (No model.)

Claim.—1. The art of molding spoke-wheels, which consists in forming a non-parting green or damp sand mold within the confines of a rim-pattern having ribs at the inner side thereof and adapted to be parted transversely of the rim, placing boss-patterns loosely upon separate spokes and setting the spokes at the ribs of the rim-pattern and also setting the boss-patterns against the ribs of the rim-pattern while forming the mold, setting up sectional prepared molds or patterns for the hub while forming the green-sand mold, parting the rim-pattern and withdrawing the same outwardly as from its axis from the green-sand mold, removing the boss-patterns from the spokes and also from the green-sand mold, and setting a separate mold about the green-sand mold, substantially as described.

2. The art of molding spoke-wheels, which consists in forming a non-parting green-sand mold within the confines of a rim-pattern having holes therein to receive the ends of the spoke-patterns, setting the spoke-patterns in the holes in the rim-pattern while forming the mold, drawing the spoke-patterns longitudinally from the holes in the rim-pattern after forming the sand mold, withdrawing the rim-pattern from the sand mold, drawing the spoke-patterns oppositely to their former movements, and setting a separate mold about the green-sand mold, substantially as described.

3. The art of molding spoke-wheels, which consists in setting a rim-pattern and a pattern for the lower end of the hub, placing separate spoke-patterns in connection with the rim and the hub patterns, setting companion hub-patterns, placing other separate spoke-patterns in connection with the rim and the companion hub patterns, gaging and adjusting the rim-pattern relatively to the hub-patterns, forming a green-sand mold between the rim-pattern and the hub-patterns, drawing the spoke-patterns longitudinally toward the axis of the hub-patterns, drawing the rim-pattern outwardly as from its axis from the sand mold, setting the mold for the outer face of the rim, and setting a plate-cover upon the mold, substantially as described.

4. The art of making spoke-wheels, which consists in setting a sectional rim-pattern and also a separated sectional hub-pattern, placing boss-patterns loosely upon separate spoke-patterns and setting the spoke-patterns in connection with the rim and the hub patterns, setting the boss-patterns against the rim-pattern, forming a sand mold without a parting, shifting the spoke-patterns longitudinally, removing the rim-pattern from the mold without disturbing the hub-pattern, shifting the spoke-patterns, removing the boss-patterns from the spoke-patterns and also from the mold, setting a pattern for the outer face of the rim, and pouring the metal between two separate plates to form the sides of the rim, substantially as described.

5. The art of making spoke-wheels, which consists in building up a sectional hub-exterior pattern, setting a sectional rim-pattern of full width of face, setting spoke-patterns separately in connection with the hub and the rim patterns, forming a non-parting solid green-sand mold, shifting the spoke-patterns inwardly, removing the rim-pattern without disturbing the hub-pattern, shifting the spoke-patterns outwardly, setting the rim-face chills, setting a band concentrically about the rim-face chills, placing dry sand between the rim-face chills and the band, setting opposing chill-plates so as to form the sides of the rim, casting the metal between the opposing chill-plates and also within the hub-exterior pattern, and then removing the chills and the hub-pattern and the sand mold, leaving the spoke-patterns attached to the castings.

6. The art of molding spoke-wheels having ribs at the inner face of the rim, which consists in setting a rim-pattern having ribs thereon and a pattern for the lower end of the hub, placing separate spokes in connection with the hub-pattern and also with the rim-pattern at the ribs, setting boss-patterns loosely on the spokes against the rim-ribs, setting companion hub-patterns, placing other spokes in connection with the rim-ribs and the hub-patterns, forming a green-sand mold between the rim-pattern and the hub-patterns, parting the rim-pattern transversely thereof and drawing the parts thereof outwardly as from its axis away from the peripheral face of the sand mold, removing the boss-patterns from the mold, and setting the mold for the outer face of the wheel-rim, substantially as described.

707,214. ART OF TREATING REBELLIOUS ORES OF THE PRECIOUS METALS. WILLIAM F. DOWN, Jersey City, N. J. Filed Nov. 27, 1901. Serial No. 83,835. (No specimens.)

Claim.—1. The process of treating ores containing precious metals and rebellious elements which consists in intimately mixing the ore with a sodium compound and an agent capable of releasing metallic sodium therefrom, heating the mixture to a temperature sufficient to release the sodium, whereby a combination of the sodium with the rebellious elements of the ore results and leaves the precious metal distributed in a free state throughout the mass, permitting the volatile impurities and compounds to escape and finally recovering the precious metal from the mass.

2. The process of treating ores containing precious metals and rebellious elements which consists in intimately mixing the ore with a sodium compound and an agent capable of releasing metallic sodium therefrom, heating the mixture to a temperature sufficient to release the sodium, whereby a combination of the sodium with the rebellious elements of the ore results and leaves the precious metal distributed in a free state throughout the mass, permitting the volatile impurities and compounds to escape, removing the non-volatile compounds formed and finally recovering the precious metal from the mass.

3. The process of treating ores containing precious metals and rebellious elements which consists in roasting the same, in intimately mixing the roasted ore with a sodium compound and an agent capable of releasing metallic sodium therefrom, heating the mixture to a temperature sufficient to release the sodium, whereby a combination of the sodium with the rebellious elements of the ore results and leaves the precious metal distributed in a free state throughout the mass, permitting the volatile impurities and compounds to escape and finally recovering the precious metal from the mass.

4. The process of treating ores containing precious metals and rebellious elements which consists in roasting the same, in intimately mixing the roasted ore with a sodium compound and an agent capable of releasing metallic sodium therefrom, heating the mixture to a temperature sufficient to release the sodium, whereby a combination of the sodium with the rebellious elements of the ore results and leaves the precious metal distributed in a free state throughout the mass, permitting the volatile impurities and compounds to escape, removing the non-volatile compounds formed and finally recovering the precious metal from the mass.

5. The process of treating ores containing precious metals and rebellious elements which consists in intimately mixing the ore with a sodium compound and carbon, heating the mixture to a temperature sufficient to release the sodium, whereby a combination of the sodium with the rebellious elements of the ore results and leaves the precious metal distributed in a free state throughout the mass, permitting the volatile impurities and compounds to escape and finally recovering the precious metal from the mass.

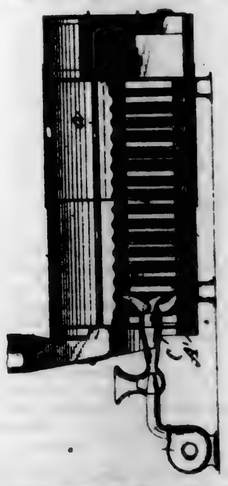
6. The process of extracting gold from ores containing arsenic, tellurium, sulfur or similar impurities which consists in roasting the ores; reducing the roasted mass to a finely-divided state; making the powder so formed into briquets with suitable proportions of a sodium compound and carbon; heating the briquets to a temperature sufficient to release the sodium; removing the remaining compounds of sodium and the impurities, and recovering the gold from the residue.

707,215. YARN-SPINNING APPARATUS. GEORGE O. DRAPER, Hopedale, Mass., assignor to Draper Company, Portland, Me., and Hopedale, Mass. Filed Oct. 26, 1900. Serial No. 34,421. (No model.)

Claim.—1. An annular seat having a plurality of radial recesses therein, a rotatable ring capable of axial and radial movement relatively to said seat, an overhanging lint-guard on the ring, and a stop extended through each recess in the seat to engage the ring beneath the guard and limit upward movement of the ring.

2. An annular seat having attaching ears on the exterior thereof, and a radial recess through the seat opposite each ear, a rotatable ring axially movable relatively to the seat, and having an external annular groove, a limiting-stop secured to each ear of the seat and extended through the annular recess of the ring, and a lint-guard on the latter overhanging the ring-recess.

707,216. STEAM-BOILER. HENRY A. DOE, Jr., Charleston, S. C. Filed Sept. 3, 1901. Serial No. 74,149. (No model.)



Claim.—1. The combination of an internal cylindrical furnace, an annular fire-brick chamber therein having tangentially-arranged passages for the escape of the gases, and means for introducing fuel into said chamber, substantially as and for the purpose described.

2. In a furnace, the combination of a cylindrical internally-corrugated fire-chamber, and a jet-head located within the fire-chamber through which the fuel is introduced thereto, said head causing the burning gases to gyrate in the fire-chamber, substantially as and for the purpose set forth.

3. The combination of the boiler, a cylindrical internally-corrugated furnace arranged within the same, a jet-head located within the furnace for causing the burning gases to gyrate violently within said furnace and against the walls thereof, and means for feeding fine fuel to the jet-head, substantially as set forth.

4. The combination of the boiler, a cylindrical internally and annularly corrugated furnace arranged within the same, a jet-head located within the furnace for causing the burning gases to gyrate violently within and circumferentially of said furnace and against the walls thereof, and means for feeding fine fuel to the jet-head, substantially as and for the purpose set forth.

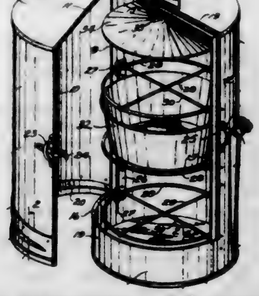
5. In a boiler-furnace, the combination of a boiler, a cylindrical furnace therein, and a cylindrical fire-brick chamber within said furnace provided with tangentially-disposed openings for the escape of gases whereby the latter are caused to circulate circumferentially within the furnace, substantially as and for the purpose set forth.

6. The combination of a boiler, a corrugated cylindrical furnace therein, a cylindrical fire-brick chamber within said furnace provided with a series of tangentially-disposed openings for the escape of gases, whereby the latter are directed against the inner wall of the furnace and caused to circulate circumferentially within the furnace and around said fire-brick chamber, substantially as and for the purpose described.

7. In a boiler-furnace, the combination of a boiler, a cylindrical furnace therein, a cylindrical fire-brick chamber within the furnace composed of a series of annular fire-bricks having tangential gas-passages, and means for feeding fuel into said chamber, the gases jetted from said chamber being caused to gyrate in the annular space between the outer walls of said chamber and the inner wall of the furnace, substantially as described.

8. In a boiler-furnace, the combination of a boiler, an internal circumferentially-corrugated cylindrical furnace, a cylindrical fire-brick chamber within the furnace, said chamber being composed of a series of annular fire-bricks having tangential flue-passages, and provided with external lugs spacing them from the walls of the furnace, and means for feeding fuel into said chamber, the gases jetted from said chamber being caused to gyrate in the annular space between the outer walls of said chamber and the inner wall of the furnace, substantially as and for the purpose set forth.

707,217. STEAM COOKING UTENSIL. GEORGE F. EDMUNDS, Chicago, Ill., assignor of one-half to Guy R. Ainsworth, Wilmette, Ill. Filed Oct. 31, 1901. Serial No. 80,800. (No model.)



Claim.—1. In a steam cooking utensil, the combination of a tank, a semicylindrical casing formed therewith and provided with a top, a door of semicylindrical form hinged to said casing, and provided at its upper end with a top, and at its lower end with a hood extending inwardly over the tank, an extension secured to the door and arranged to close the space between the door and the tank, said extension being deflected inwardly so as to rest upon said tank when the door is closed, substantially as described.

2. In a steam cooking utensil, the combination of a tank, a semicylindrical casing formed therewith and provided with a top, a door of semicylindrical form hinged to said casing and provided at its upper end with a top, and at its lower end with a hood extending inwardly over the tank, socket-strips secured to the inner face of the casing, circular shelves supported by said socket-strips and arranged one above the other for supporting the pans, and a canopy suspended from the top of the cylindrical casing to gather condensed moisture and conduct the same to the side walls of the casing and door, substantially as described.

707,218. GATE. HANS P. HANSEN, Thor, Iowa. Filed May 28, 1902. Serial No. 108,713. (No model.)

Claim.—1. The combination of a swinging gate having a latch, operating ropes or cables connected with the gate, slidable blocks capable of upward and downward movement and located at opposite sides of the gate, supplemental latches movably mounted on the blocks, and means for connecting the supplemental latches with the operating ropes or cables, substantially as described.

2. The combination of a swinging gate having a latch, slidable blocks located at opposite sides of the gate and capable of upward and downward movement, supplemental latches movably mounted on the blocks, and operating mechanism connected with the gate and with the latches, substantially as described.

3. The combination of a swinging gate having a latch, slidable blocks mounted at opposite sides of the gate, supplemental latches carried by the blocks, and operating mechanism connected with the gate and with the latches, substantially as described.

4. The combination of a swinging gate, inclined bars located at opposite sides of the gate, blocks slidably mounted on the inclined bars and capable of upward and downward movement, supplemental latches pivotally mounted on the blocks and arranged to swing horizontally, and operating mechanism connected with the gate and with the latches, substantially as described.

5. The combination of a swinging gate having a latch, a hinge-post, a horizontal bar extending from the hinge-post, inclined braces supporting the horizontal bar and provided with slots, blocks slidably mounted in the slots, supplemental latches mounted on the blocks and carried by the same, operating ropes or cables secured at the back of the gate and connected with the same and with the latch of the gate, said ropes or cables having their outer portions supported by the horizontal bar, and means for connecting the supplemental latches with the operating ropes or cables, substantially as described.

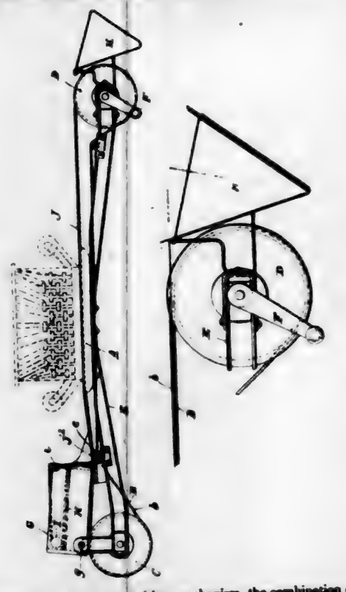
6. The combination of a swinging gate, blocks slidably mounted at opposite sides of the gate, supplemental latches mounted on the blocks, inclined rods connected with the supplemental latches, links supporting the rods, and operating mechanism connected with the gate and with the rods, substantially as described.

707,219. GLUING-MACHINE. Willis F. Efferson, Ladoga, Ind. Filed Nov. 19, 1901. Serial No. 82,881. (No model.)

Claim.—1. The combination, in a gluing-machine, of a suitable receptacle for the glue, and a gluing-wheel mounted to revolve in said receptacle and composed of disks, one of which is of slightly-greater diameter than the others and has a serrated edge, the points or teeth whereof are adapted to engage with the article being glued as the same passes over the wheel, whereby the surfaces are caused to move in unison, the periphery of said wheel being otherwise free of parts extending above its bearing-face, all substantially as set forth.

2. The combination, in a gluing-machine, of a suitable receptacle for the glue, and a gluing-wheel mounted to revolve in said receptacle and composed of three disks, the two side disks having circumferential grooves in their periphery but being otherwise smooth, and the central disk being of somewhat greater diameter than the side disks and having a serrated edge the points or teeth whereof are adapted to engage with the article being glued as the same passes over the wheel, whereby the surfaces are caused to move in unison, while a suitable supply of glue is distributed over said article on both sides of the point where they engage.

707,220. FEEDING ATTACHMENT FOR TYPE-WRITING MACHINES. Matthew S. Sylan, New York, N. Y., assignor to Elliott & Hatch Book Typewriter Company, a Corporation of New York. Filed Nov. 18, 1901. Serial No. 82,421. (No model.)



Claim.—1. In a type-writing mechanism, the combination of a flat bed or platen, a writing mechanism located thereover, acting in a downward direction, an endless carrier-belt extending over and bearing upon the surface of the platen and returned thereunder, a manual device for advancing said belt intermittingly at will, a magazine arranged to deliver cards automatically to the belt at one end, and a holder arranged to receive the cards from the belt at the opposite end.

2. In a type-writing machine, the combination of a flat bed or platen, a downwardly-acting writing mechanism located thereover, an endless belt extending across the surface of the platen beneath the writing mechanism and returned beneath the platen, a supplemental frame and rolls to sustain the said belt, and means for imparting an intermitting movement thereto at will.

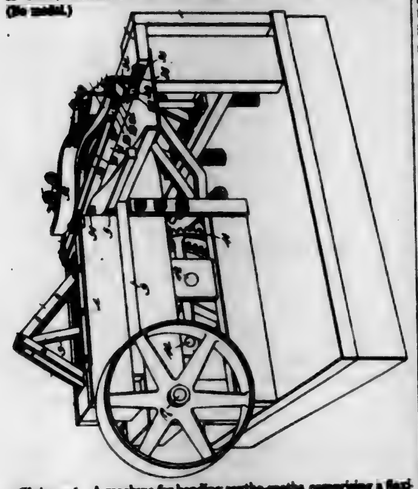
3. A portable card-feeding attachment for a flat-bed type-writer, comprising the frame E, rolls sustained in the ends of said frame, one of them provided with a manual operating device, an endless apron extended around said rolls, a magazine for cards mounted upon the frame over one end of the belt, and a card-receiver attached to the frame at the opposite end of the belt.

4. In a type-writing machine, the combination of the flat bed or platen, the downwardly-acting writing mechanism located thereover, the endless feed-apron extending over the surface of the platen, the hinged graduating mechanism G resting upon the belt, and a follower I therein, substantially as described and shown.

5. In a card-feeding attachment for type-writing machine, an endless apron B to deliver the cards, and a retaining-drum D for said apron, in combination with a V-shaped receiver arranged adjacent to the drum and below the upper surface of the belt, substantially as described, whereby each incoming card is adapted to tip backward in the receiver the preceding card.

6. In a type-writing machine and in combination with a downwardly-acting mechanism, a flat bed or platen thereunder, a carrier-apron mounted to travel upon and around the platen, a magazine mounted over one end of the apron and arranged to deliver the cards thereto, guides to determine the course of the cards as they are advanced by the apron, and an overlying pressure device acting on the edge of the cards to hold them flatly upon the apron.

707,221. MACHINE FOR BENDING SCYTHE-SNATHS. Orson M. Fish, Charlotte, Mich. Filed Mar. 18, 1902. Serial No. 98,332. (No model.)



Claim.—1. A machine for bending scythe-snaths, comprising a flexible jacket for inclosing opposite sides of the blank, means for imparting the horizontal bends to the blank, means for imparting progressive end pressure to the blank while the said bends are being formed, and means for imparting the vertical bends to the blank.

2. A machine for bending scythe-snaths, comprising a flexible jacket for inclosing opposite sides of the blank, means coacting therewith to impart the horizontal bends to the blank, mechanism operated by the said means for imparting end pressure to the blank while the said bends are being formed, and means for imparting vertical bends to the blank.

3. In a machine for bending scythe-snaths, the combination of means for imparting the horizontal bends to the blank, a flexible jacket for inclosing opposite sides of the blank, means coacting with the jacket to impart end pressure to the blank, and means for forcing the blank from the jacket and for imparting the vertical bends thereto.

4. In a machine for bending scythe-snaths, the combination of means for imparting the horizontal bends to a snath-blank, an adjustable flexible jacket for inclosing the opposite sides of the blank, mechanism actuated by the said means for imparting progressive end pressure to the blank, and means for forcing the blank from the jacket and for imparting the vertical bends thereto.

5. A machine for bending scythe-snaths, comprising means for imparting the horizontal bends to the snath-blank, a jacket for inclosing the opposite sides of the blank and to be flexed by the said means, and vertically-movable means for forcing the blank from the jacket and for imparting the vertical bends thereto.

6. A machine for bending scythe-snaths, comprising an adjustable flexible jacket for inclosing opposite sides of the blank, means coacting with the jacket to impart horizontal bends to the blank, and mechanism operated by the said means for imparting end pressure to the blank while the said bends are being formed.

7. A machine for bending scythe-snaths comprising a flexible jacket for receiving the blank, a plunger for imparting the horizontal bends to the blank, means for imparting progressive end pressure to the blank while the said bends are being formed, and means for imparting the vertical bends to the blank.

8. A machine for bending scythe-snaths comprising a flexible jacket for receiving a blank, a plunger coacting therewith to impart the horizontal bends to the blank, means operated by the plunger for imparting end pressure to the blank while the said bends are being formed, and means for imparting the vertical bends to the blank.

9. A machine for bending scythe-snaths comprising a flexible jacket for inclosing opposite sides of the blank, a plunger coacting therewith to impart the horizontal bends to the blank, and means operated by the plunger for imparting end pressure to the blank while the said bends are being formed.

10. In a machine for bending scythe-snaths, the combination of a movable plunger for imparting the horizontal bends to a snath-blank, a flexible jacket to receive the blank, means coacting with the jacket to impart end pressure to the blank, and means for forcing the blank from the jacket and for imparting the vertical bends thereto.

11. In a machine for bending scythe-snaths, the combination of a plunger for imparting the horizontal bends to a snath-blank, an adjustable flexible jacket to receive the blank, means actuated by the plunger for imparting progressive end pressure to the blank, and means for forcing the blank from the jacket and for imparting the vertical bends thereto.

12. A machine for bending scythe-snaths comprising a plunger for imparting the horizontal bends to a snath-blank, a jacket to receive the blank and to be flexed by the plunger, and a vertically-movable plunger for forcing the blank from the jacket and for imparting the vertical bends thereto.

13. In a machine for bending scythe-snaths, a plunger for imparting the horizontal bends to a snath-blank, a toggle-lever associated with the plunger, continuously-operating driving mechanism operatively connected with the lever, a jacket to receive a snath-blank, a vertically-movable plunger for imparting the vertical bends to the snath-blank, and intermittently-operating mechanism connecting the latter plunger with the said driving mechanism.

14. In a machine for bending scythe-snaths, a plunger for imparting the horizontal bends to a snath-blank, continuously-operating mechanism associated therewith for imparting reciprocatory movements thereto, a blank-receiving jacket coacting with the plunger, a vertically-reciprocatory plunger for imparting the vertical bends to the blank, and intermittently-operating mechanism connecting the latter plunger with the said continuously-operating mechanism.

15. In a machine for bending scythe-snaths, a plunger for imparting the horizontal bends to a snath-blank, a jacket to receive the blank, means coacting with the jacket for imparting end pressure to the blank, a former for imparting the vertical bends to the blank and for forcing it from the jacket, means disposed in the path of travel of the jacket and actuated by the forward movement of the plunger to operate the end-pressure-imparting means, and means connecting the end-pressure-imparting means and the plunger whereby upon rearward movement of the latter to return the pressure-imparting means to its normal position.

16. In a machine for bending scythe-snaths, the combination with a flexible jacket for inclosing opposite sides of a snath-blank, of means coacting with the jacket for imparting end pressure to a contained blank.

17. In a machine for bending scythe-snaths, the combination with a flexible jacket for inclosing opposite sides of a snath-blank and having its members adjustable, of adjustable means coacting with the jacket for imparting end pressure to a contained blank.

18. In a machine for bending scythe-snaths, the combination of a horizontally-movable plunger, a flexible blank-receiving jacket disposed in advance thereof, means actuated by the plunger for imparting end pressure to the contained blank, a stationary head, a vertically-movable plunger for imparting the vertical bends to the snath-blank and for forcing it from the jacket, and a form disposed below the latter plunger to receive the blank as it is forced from the jacket.

19. A machine for bending scythe-snaths embodying in its construction, a stationary head or die, the operative face of which contains all of the horizontal bends of a scythe-snath, a movable former or plunger, the operative face of which also contains all of the said bends, a vertically-reciprocatory former, the operative face of which contains all of the vertical bends of the snath, and a removable frame or form, the bottom of which contains all of the vertical bends and its sides all of the horizontal bends of the snath.

20. A machine for bending scythe-snaths embodying in its construction a blank-receiving jacket, means coacting therewith to impart end pressure to the snath-blank, a stationary head or die, the operative face of which contains all of the horizontal bends of the snath, a movable former or plunger, the operative face of which also contains all of the said bends, a vertically-reciprocatory former, the operative face of which contains all of the vertical bends of the snath, and a removable frame or form, the bottom of which contains all of the vertical bends and its sides all of the horizontal bends of the snath.

21. In a machine for bending scythe-snaths, means for imparting

the horizontal bends to the snath-blank, continuously-operating mechanism associated with said means for imparting reciprocatory movements thereto, a blank-receiving jacket coacting with the bending means, vertically-reciprocatory means for imparting the vertical bends to the blank, and intermittently-operating mechanism connecting the latter means with the continuously-operating mechanism.

22. In a machine for bending scythe-snaths, the combination with reciprocatory belly-bend-forming means and a flexible jacket for inclosing opposite sides of a snath, of end-pressure-applying mechanism, and a head connected with the said mechanism and disposed within the range of flexure of the said jacket.

23. In a machine for bending scythe-snaths, the combination with reciprocatory belly-bend-forming means and a flexible jacket for inclosing opposite sides of a snath-blank, of end-pressure-applying mechanism, and a head adjustably connected with the said mechanism, and disposed within the range of flexure of the said jacket.

24. In a machine for bending scythe-snaths, the combination with a reciprocatory belly-bend-forming member provided with a slot, and a flexible jacket for inclosing opposite sides of a snath-blank, of end-pressure-applying mechanism, a head adjustably connected with the said mechanism and disposed within the range of flexure of the said jacket to close the said mechanism on the forward movement of the said member, and a bar having one end connected with the said mechanism and its other end disposed within the slot of the said member and operating on the backward movement thereof to open the end-pressure-applying mechanism.

25. In a machine for bending scythe-snaths, the combination with the belly-bend-forming means, of end-pressure-exerting mechanism comprising pivoted levers having their forward terminals formed to constitute abutments to engage the ends of the snath-blanks, and their rear terminals slotted, and a bar having one terminal disposed within the slotted ends of the levers and its other terminal operatively associated with the belly-bend forming means.

26. In a machine for bending scythe-snaths, the combination of a stationary head and a movable plunger each having its operative face containing all of the horizontal bends of a scythe-snath, of a vertical plunger having its under face containing all of the vertical bends of a snath.

27. In a machine for bending scythe-snaths, the combination of a stationary die and a horizontally-reciprocatory plunger, each having its operative face provided with all of the horizontal bends of a scythe-snath, of a vertically-reciprocatory plunger having its under face provided with all of the vertical bends of the snath, and a removable form or frame disposed below the latter plunger, the bottom of the form having all of the vertical bends and its sides all of the horizontal bends of a snath.

28. In a machine for bending scythe-snaths, the combination with the belly-bend-forming means, of end-pressure-exerting mechanism actuated by the said means, and a flexible jacket associated with the said mechanism for inclosing opposite sides of a snath-blank.

29. In a machine for bending scythe-snaths, the combination with the belly-bend-forming means, of end-pressure-exerting mechanism actuated by the said means, and a two-membered flexible blank-receiving jacket associated with the said mechanism, one terminal of one of the members of the jacket having a slide-bearing associated therewith.

30. In a machine for bending scythe-snaths, belly-bend-forming means having toggle mechanism associated therewith, vertical-bend-forming means having toggle mechanism associated therewith, positively-driven master-wheels operatively connected with the toggle mechanism of the belly-bend-forming means, said wheels being connected by a wrist-pin, a bar having one end connected with the toggle mechanism of the vertical-bend-forming means, and its opposite end provided with a nose disposed in the path of movement of the wrist-pin, means for supporting the latter end of the bar in operative position with relation to the wrist-pin, and a lever fulcrumed to the frame of the machine and having one terminal operatively connected with the bar and its other terminal disposed in the path of movement of the belly-bend-forming means.

31. In a machine for bending scythe-snaths, belly-bend-forming means having toggle mechanism associated therewith, vertical-bend-forming means having toggle mechanism associated therewith, positively-driven master-wheels operatively connected with the first-named toggle mechanism, said wheels being connected by a wrist-pin, springs coacting with the second-named toggle mechanism and operating normally to hold the vertical-bend-forming means normally raised, a bar having one end connected with the toggle mechanism of the vertical-bend-forming means and its opposite end provided with a nose disposed in the path of movement of the wrist-pin, means for supporting the latter end of the bar in operative position with relation to the wrist-pin, and a lever fulcrumed on the frame of the machine and having one terminal operatively connected with the bar and its other terminal disposed in the path of movement of the belly-bend-forming means.

707,222. AUTOMATIC LINE-CATCH FOR TROLLEY-WIRES.

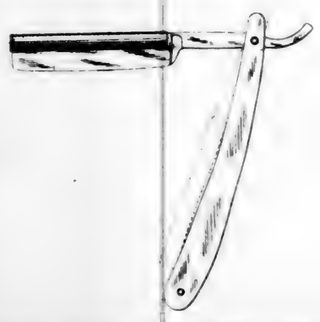
GEORGE R. FLOYD, Cincinnati, Ohio. Filed Dec. 31, 1901. Serial No. 87,890. (No model.)

Claim.—1. In combination with a trolley-wire an automatic safety device consisting of a supplemental wire or rod, connected to the trolley-wire at opposite sides of and beyond a point of probable breakage, by suitable holding-ears, said wire having a limited longitudinal movement in said ears.

2. In combination with a trolley-wire having holding-ears fixed to it at opposite sides of and beyond a point of probable breakage, an automatic safety device consisting of a supplemental wire or rod connected to said ears, the ends of said wire or rod having a limited longitudinal movement in said ears.

3. In combination with a trolley-wire and holding-ears thereon at opposite sides of and beyond a point of probable breakage, an automatic safety device consisting of a supplemental wire or rod leading from a fixed point and connected to the ears and having a limited longitudinal movement therein.

707,223. RAZOR. CHARLES FREITAG, Brooklyn, N. Y. Filed Jan. 11, 1902. Serial No. 89,263. (No model.)



Claim.—A removable gage for razor-blades, consisting of a hollow thin sheet-metal cylinder slotted longitudinally for the reception of the back of the blade, the free edges of the cylinder being folded to present an increased frictional bearing-surface upon the blade, to hold the gage firmly in place and prevent the cylindrical body from rocking on the blade, as set forth.

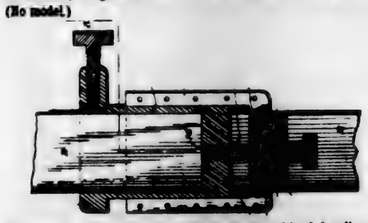
707,224. PROCESS OF PRESERVING WOOD. TOMASO GIUSSANI, Milan, Italy. Filed June 26, 1901. Serial No. 66,154. (No specimens.)

Claim.—1. The process for preserving wood, consisting in first immersing the wood in a mixture of anthracene and pitch, heated to a temperature over 100° centigrade whereby the water contained in the pores of the wood is vaporized and a layer of the mixture is deposited upon the surface of the wood and then in immersing the wood in a second cold bath whereby the surface layer remaining from the first bath is made to penetrate the surface of the wood and thereby form a dense protecting-layer, substantially as described.

2. The process for preserving wood, consisting in first immersing the wood in a mixture of anthracene and pitch heated to a temperature over 100° centigrade, whereby the water contained in the pores of the wood is vaporized, and then in immersing the wood in a second bath consisting of two liquids of different densities and incapable of being mixed mechanically whereby the latter liquids penetrate the wood and become mixed with the material of the first bath, within the pores of the wood and form a dense protecting-layer, substantially as described.

3. The process for preserving wood, consisting in first immersing the wood in a mixture of anthracene and pitch heated to a temperature over 100° centigrade whereby the water contained in the pores of the wood is vaporized, and then immersing the wood in a second bath consisting of layers of a solution of chlorid of zinc and creosote whereby the latter liquids penetrate the wood and become mixed with the material of the first bath within the pores of the wood and form a dense protecting-layer, substantially as described.

707,225. EXTENSION-FITTING FOR LEVELING-RODS. GEO S. GOODALE, Houghton, Mich. Filed Dec. 9, 1901. Serial No. 85,375 (No model.)

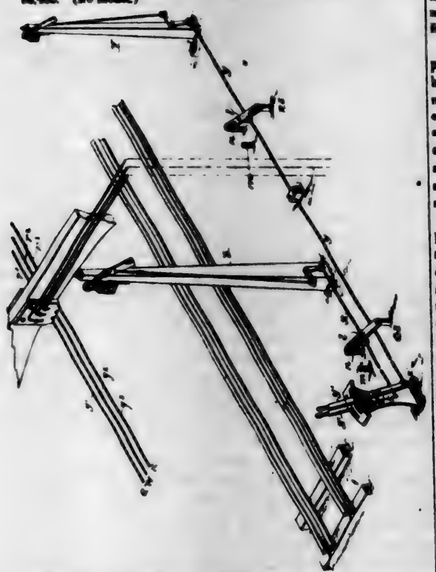


Claim.—1. The combination with the front and back leveling-rods; of a casing fixed to the front rod and through which the back rod slides, a collar slidably mounted upon the back rod above said casing, a frame sliding in the casing and fixed to the collar, a fastening carried by the collar for locking it in adjusted position on the back rod, and a screw swiveled to the base of the casing and working in said frame for setting the rod to exact adjustment after the collar has been locked thereto, substantially as set forth.

2. The combination with the front and back leveling-rods; of a casing fixed to the front rod and through which the back rod slides, a collar mounted to slide upon the back rod above the casing, a frame sliding in the casing and to which the collar is connected, means for locking the collar in adjusted position, a screw swiveled to the bottom of the casing and operatively connected to said frame for setting the rod to exact adjustment after the collar has been locked thereto, and means upon the casing for locking said screw in adjusted position, substantially in the manner set forth.

3. The combination with the front and back leveling-rods; of a casing fixed to the front rod and through which the back rod slides, a collar slidably mounted upon the back rod above said casing, a frame sliding in the casing and fixed to the collar, a fastening carried by the collar for locking it in adjusted position on the back rod, an adjusting-screw connecting the casing and sliding frame for adjusting the sliding frame, said screw having a collar swiveled in an aperture in the bottom of the casing, a plate closing said aperture, and means upon said plate for locking the screw in adjusted position, substantially as set forth.

707,226. ELECTRIC BLOCK SYSTEM FOR RAILWAY-TRAINS. JAMES T. HARDAY, New York, N. Y. Filed Mar. 15, 1902. Serial No. 98,405. (No model.)



Claim.—1. In an electric block-signal system for railway-trains, a normally open signal-circuit completed through contacts on the locomotive whenever and so long as the latter is on the block, and having branch circuit connections including the one a safety-signal and the other a caution or danger signal, both of which are on the locomotive and in convenient proximity to the engineer, and means controlled from the tower or cabin appropriate to the block for completing the circuit through either one of said signals to the exclusion of the other.

2. In an electric block-signal system for railway-trains, a normally open signal-circuit completed through contacts on the locomotive whenever and so long as the latter is on the block, and having branches including the one a safety-signal and the other a caution or danger signal, both of which are on the locomotive and in convenient proximity to the engineer, a track-signal or semaphore, an electrical switch and connections between the same and the track-signal whereby the electrical switch shall be thrown to complete the circuit through that branch which includes the safety or the caution or danger signal on the locomotive according as the track-signal is brought to safety or danger substantially as hereinbefore set forth.

3. An electrical block-signal system in which the block is subdivided into caution and danger sections each having a signal-circuit electrically independent of the other, each circuit being normally open and completed through contacts on the locomotive whenever and so long as the latter is on the block-section to which the circuit pertains, and having branches including the one a safety-signal and the other a caution or a danger signal as the case may be, all of said signals being on the locomotive, in combination with means controlled from the tower or cabin appropriate to the block for completing either circuit at will through either one of its branches substantially as and for the purposes hereinbefore set forth.

707,227. CHAIN-STITCH SEWING-MACHINE. HENRY J. HANCOCK, New York, N. Y., assignor of one-half to William S. Jessup, New York, N. Y. Filed Dec. 4, 1901. Serial No. 84,606. (No model.)

Claim.—1. A chain-stitch sewing-machine comprising a frame, a crank-shaft provided at one end with a crank, means to rotate said shaft, two needle-bars carrying needles mounted on said crank, a cam-lever positively operated by said crank and controlling one of said needle-bars, a cloth-plate, and a presser-foot provided with a slot adapted to carry one needle back, or at one side of the other in its descent, and to hold the needles parallel during the descent of the other needle, for the purpose set forth.

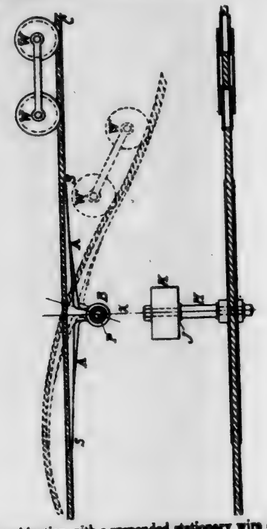
2. A chain-stitch sewing-machine comprising a frame, a crank-shaft provided at one end with a crank, means to rotate said shaft, two needle-bars carrying needles mounted on said crank, a cam-lever pivotally connected with the frame above said shaft and provided with a slot, said crank being provided with a projection in engagement with the walls of said slot in the cam-lever, said cam-lever being in engagement with one of said needle-bars, a cloth-plate, and a presser provided with a slot adapted to carry one needle back, or at one side of the other in its descent, and to hold the needles parallel during the descent of the other needle, as and for the purpose set forth.

3. A chain-stitch sewing-machine comprising a frame, a crank-shaft provided with a crank and means to rotate said shaft, a cross-bar fixed on said crank, a needle-bar pivotally mounted on said crank, a second needle bar pivotally mounted on the free end of said cross-bar and carrying an eye-pointed needle, a presser-foot provided with a slot adapted to carry the respective needle back of the eye-pointed needle during its descent and to hold the needles parallel during the descent of the eye-pointed needle, a cam-lever mounted on the frame and provided with a cam-slot and a stud engaging a slot in one of said needle-bars, and a shoulder on said crank adapted to engage said cam-lever to positively control said needle-bars, as and for the purpose set forth.

4. A chain-stitch sewing-machine comprising a frame, a crank-shaft provided with a crank having a shoulder, two needle-bars mounted on said crank, a cam-lever adapted to positively control said needle-bars, a presser-foot provided with a slot adapted to control the movement of the needles during a portion of their movement, a lever pivoted on the frame, a cloth-plate mounted thereon, and a cam-lever provided with serrations or teeth adapted to engage said last-named lever, as and for the purpose set forth.

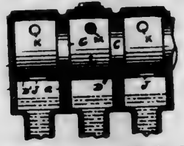
707,228. SUPPORT FOR SUSPENDED-CABLE-TRACK ROADS. HENRY M. HARDING, New York, N. Y. Filed Dec. 22, 1899. Serial No. 741,228. (No model.)

Claim.—1. In combination with a suspended stationary wire-cable trackway, for a suspended car or truck, of a bracket, the end portions of which are constructed of elastic material making them flexible, substantially as described, and for the purpose set forth.



2. In combination with a suspended stationary wire cable for a suspended car or truck of a bracket, being both flexible and pivoted, substantially as described.

707,229. **SECTIONAL HEATING-BOILER.** ELBERT O HASKINS, Rutherford, N. J. Filed Nov. 1, 1901. Serial No. 80,795. (No model.)



Claim.—In a heating-boiler, the combination with a series of sections provided with openings in their faces for establishing communication with adjacent sections, push-nipples inserted in said openings and a partition within each section, forming a compartment around said openings and push-nipples, and extending from one wall to the other of said section, and made integral therewith, this partition having an opening for establishing communication between the compartment formed by said partition and the interior of the section within which said compartment is formed, said sections each having an opening in the edge wall adjacent to the opening in said partition, substantially as set forth.

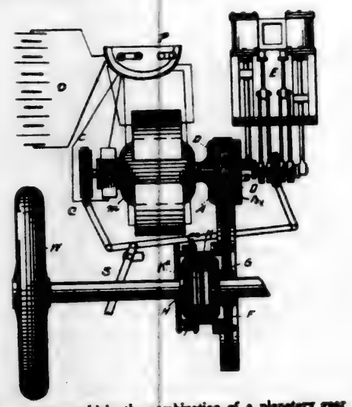
707,230. **AUTOMOBILE.** JOHN C. HENRY, Denver, Colo.; Susie A. Henry, executrix of said John C. Henry, deceased, assignor to Stanley Electric Manufacturing Company, a Corporation of New Jersey. Filed Apr. 1, 1901. Serial No. 53,996. (No model.)

Claim.—1. In combination with an electric motor and a pressure-operated motor, a planetary gear intermediate and connected to said motors, and to a device to be driven, and clutch devices arranged so that any one of said motors may be held stationary for the purpose set forth.

2. In a motor-vehicle, the combination of a planetary gear connected to drive the vehicle, a fluid-pressure motor and an electric motor connected respectively to different parts of said gear all arranged so that either of said motors may drive the vehicle independently.

3. In a motor-vehicle, the combination of a planetary gear connected to drive the vehicle, a fluid-pressure motor and an electric motor connected respectively to different parts of said gear, and clutching means for arresting either of said gear parts all arranged so that either or both of said motors may drive the vehicle.

4. The combination of an electric motor and an engine, a planetary gear connecting said parts to one another and to a device to be driven, means for clutching either one of these parts so as to arrest either of the motors or the driven part, and a storage battery connected to the motor so as to be charged by the same as a dynamo, when the driven part is arrested.



5. In a motor-vehicle, the combination of a planetary gear connected to drive the vehicle, an electric motor, and a pressure-engine connected with different parts of said gear, clutches adapted to arrest either of said gear parts, means for arresting the motion of the vehicle, and a storage battery connected with the electric motor, whereby the vehicle may be driven from either or both of said motors, or on arresting the vehicle, the pressure-engine may be caused to drive the electric motor as a dynamo to charge the battery.

6. In a motor-vehicle, an engine and a motor, a planetary gear having a central pinion keyed to the armature-shaft of the motor, the planetary pinions and a part carrying same and connected to the engine, an internal gear, engaging said planetary, gear to which the vehicle-driving mechanism is connected, and clutches arranged to arrest the movement of the central pinion, planetary gear or the driving-gear of the vehicle.

707,231. **PROCESS OF MANUFACTURING ARTIFICIAL FUEL.** EDWARD J. HOFFMAN, Chicago, Ill., assignor of one-half to Charles W. ADAMS, Chicago, Ill. Filed Nov. 29, 1901. Serial No. 84,116. (No specimens.)

Claim.—1. The process, substantially as described, of manufacturing artificial fuel, consisting in combining hydrocarbon oil with caustic soda and non-siliceous, non-kaoliferous earth in about the proportions specified, agitating the mixture and subjecting the same to moderate heat until a complete chemical combination is effected between the oil and alkali, and a complete admixture is effected with said earthy absorbent.

2. The process, substantially as described, of manufacturing artificial fuel, consisting in mixing hydrocarbon oil with a sufficient proportion of alkaline salt to produce complete concretion of all the oil and a sufficient quantity of non-siliceous, non-kaoliferous earth to fully absorb the oleaginous mixture, heating and agitating the ingredients until complete concretion and admixture results, and finally compressing the same in molds.

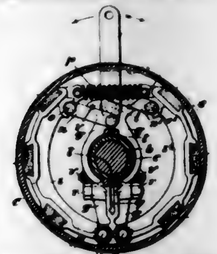
3. The process, substantially as described, of manufacturing artificial fuel, consisting in mixing hydrocarbon oil, caustic soda and an earthy absorbent, in the proportion by weight of about eight parts of oil, one part of soda, and two hundred and fifty parts of non-siliceous, non-kaoliferous earth, and heating and agitating the ingredients until a complete chemical reaction is effected between the oil and soda, and a thorough admixture is made with the earthy absorbent.

4. The process, substantially as described, of manufacturing artificial fuel, consisting in mixing hydrocarbon oil, caustic soda and vegetable loam in the proportion by weight of about eight parts of oil, one part of soda, and two hundred and fifty parts of loam, heating the mixture to from about 180° to about 212° Fahrenheit, and agitating the same until complete concretion results.

5. As an improved article of manufacture, an artificial fuel consisting of hydrocarbon oil and caustic soda chemically combined and mechanically mixed with an absorbent material in about the proportions specified.

6. As an improved article of manufacture, an artificial fuel compressed in the form of briquets molded from a compound consisting of hydrocarbon oil and caustic-soda salt chemically combined with each other and mechanically mixed with an absorbent material in about the proportions specified.

707,232. **FRICTION-BRAKE.** HENRY A. HOUSE, Jr., Hampstead, England. Filed Feb. 25, 1902. Serial No. 95,696. (No model.)

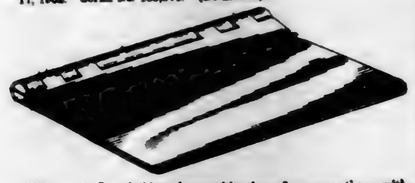


Claim.—In combination, a cylinder *c*, a fixing secured to the axle and extending above and below the said axle, a pair of brake-levers pivoted to the lower end of the fixing and extending thence upwardly and in proximity to the inner face of the cylinder, an operating-lever pivoted to the upper end of the fixing, links connecting the operating-lever above and below its pivot with the free ends of the brake-levers and a spring between the free ends of the brake-levers, substantially as described.

707,233. **SCREW-CUTTING DIE.** CHARLES J. JACKSON, Erie, Pa., assignor, by mesne assignments, to Reuben G. Wright, Westfield, N. Y. Filed Oct. 5, 1900. Serial No. 32,112. (No model.)

Claim.—In a screw-cutting die, the combination of the cast die-plate A having depressions and shoulders, and the chasers B cast therein having their cutting-faces arranged next to the depressions and the opposite faces against the shoulders.

707,234. **HOLDER.** HARVEY P. JOHNS, Chicago, Ill. Filed Apr. 17, 1902. Serial No. 103,371. (No model.)



Claim.—1. In a holder, the combination of cover-sections, with a pintle comprising a spring connected with one of said covers, and pintle-sections attached to the ends of said spring and connected with the opposite cover.

2. In a holder, the combination of cover-sections, with a pintle comprising a spring with reverse-wound spiral coils attached at its central portion to one of said covers, pintle-sections attached to the ends of said spring and connected with the opposite cover.

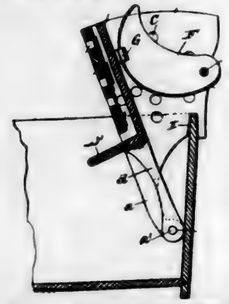
3. In a holder, the combination of cover-sections, with a pintle comprising a spring with reverse-wound spiral coils provided at its central portion with a loop to secure said spring to one of said cover-sections and lateral straight extensions, and pintle-sections having longitudinal grooves, said grooves serving to receive said extensions, said pintle-sections being connected with the opposite cover.

4. In a holder, the combination of cover-sections having annular projections, said projections having thereon opposed shoulders or offsets, and a pintle comprising a spring with reverse-wound coils connected with one of said cover-sections and pintle-sections attached to said spring, said pintle-sections being connected with the other one of said cover-sections.

5. In a holder, the combination of cover-sections, with a pintle composed of a spring with reverse-wound coils attached at its central portion to one of said covers and pintle-sections attached to said spring extending approximately to the edge of said covers, means for turning the pintle-sections and means for securing the pintle-sections to the opposite cover when the spring is adjusted.

6. In a holder, the combination of cover-sections provided with pintle-receiving perforations, with a pintle composed of a torsion-spring connected with one of said sections at the pintle, a pintle-section connected with said spring and serving to produce tension in the spring, and means for securing said pintle-section while under stress to the other cover-section, substantially as described.

707,285. **MOP-WRINGER.** JOHN VON KAHL, Akron, Ohio. Filed July 3, 1901. Serial No. 67,013. (No model.)



Claim.—1. In a mop-wringer, a perforated box portion, an imperforate presser portion pivoted to said box portion, a water-guide fixed to said presser portion, and a cam adapted to reciprocate said presser portion, substantially as shown and described.

2. In a mop-wringer, a box portion, a presser portion pivoted thereto, a water-guide secured to said presser portion, a cam adapted to oscillate said presser portion, a flaring edge on said cam, and a dovetail slot on said presser portion to receive the flaring edge on the cam, substantially as shown and described.

3. In a mop-wringer, a perforated box portion, an imperforate presser portion pivoted thereto, a water-guide secured to said presser portion, a cam to oscillate said presser portion, a flaring edge on said cam, and a dovetail slot on said presser portion to receive the flaring edge on the cam, substantially as shown and described.

4. In a mop-wringer, a perforated box portion, a rock-shaft journaled therein, a presser-board pivoted in said box portion, a water-guide on the lower edge of said presser-board, a cam keyed to said rock-shaft having a flaring edge, and a dovetail slot on the back of said presser-board to receive the flaring edge on the cam, substantially as shown and described.

707,286. **INDICATING MECHANISM FOR POST-OFFICE BOXES.** THOMAS F. KELLY, Adair, Iowa. Filed Nov. 27, 1901. Serial No. 83,873. (No model.)

Claim.—1. The combination with a plurality of mail-boxes or pigeonholes, of an indicating-arm pivotally mounted in connection with each box, means for simultaneously swinging all of said arms into indicating position and means for severally restoring them to initial position, substantially as described.

2. The combination of a plurality of pigeonholes or compartments, of an indicator movably mounted in connection with each compartment, and a movable piece or member for moving each indicator, means for simultaneously operating all of said pieces in one direction, and means for severally moving them in the opposite direction.

3. The combination with a plurality of pigeonholes or compartments, of a plurality of pivoted indicating-arms, one for each pigeonhole, a rocking piece in connection with each arm, means for simultaneously rocking

all the said pieces in one direction, and means for severally rocking them in the opposite direction, substantially as described.

4. The combination with a plurality of pigeonholes or compartments, of pivoted indicating-arms mounted in connection with each compartment, a rocking piece adapted to operate each indicating-arm, a sliding rod for rocking said pieces in one direction, and means whereby said pieces may be severally rocked in the opposite direction, substantially as described.

5. The combination with a plurality of pigeonholes or compartments, of a plurality of indicating-arms pivotally mounted in connection with said boxes, a rocking piece pivoted in proximity to each arm and having a projection designed to abut against the indicating-arm, a sliding rod passing in proximity to the said rocking pieces, means whereby the movement of the rod in one direction engages and rocks said pieces, and a key for severally rocking said pieces in the opposite direction, substantially as described.

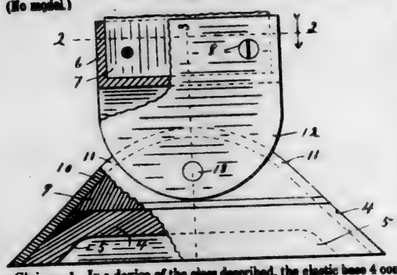
707,287. UMBRELLA-RUNNER. WILLIAM W. KENNEY and JOHN W. FOSLER, New London, Conn. Filed Oct. 3, 1901. Serial No. 77,423. (No model.)

Claim.—1. In an umbrella, in combination with ball-end ribs, a tube with split ends turned back to form sockets for said ribs, a retaining-washer mounted upon said tube, and means consisting of projections c^3, as herein set forth, for locking the said washer in its operative position.

2. In an umbrella, the combination of the ribs, the tubes having the long and short split ends forming sockets for the ribs, and the washers having recesses to receive the ends of the long ends, said ends locking the washers in place.

3. In an umbrella, the combination of the ribs, the tubes having the long and short split ends turned under to form sockets for said ribs, and said long ends having their terminals turned under, and a washer secured by said long ends.

707,288. ANTISLIPPING FOOT FOR LADDERS OR THE LIKE. ALBERT KERR, St. Louis, Mo. Filed Nov. 14, 1901. Serial No. 82,187. (No model.)



Claim.—1. In a device of the class described, the elastic base 4 composed of vulcanized rubber and having the recess 5 in its lower face, the socket 6 adapted to receive the lower end of the ladder-post, the metal ear 9 placed on top of the elastic base, and the strap 10 holding the ear 9 in position, said ear 9 being pivoted to the socket 6.

2. In a device of the class described, an elastic base having a smooth lower contacting surface, and having a recess centrally located in said lower surface, a metal ear secured to said elastic base by means of a strap, and a socket pivoted to said ear.

3. In a device of the class described, an elastic base 4 composed of vulcanized rubber, and having a smooth lower face, and having the recess 5 centrally located in said lower face, the socket 6 adapted to receive the lower end of the ladder-post, the metal ear 9 placed on top of the elastic base, the strap 10 securing said ear in position, said strap passing above the ear, and the ends of said strap being attached to the base, the flanges 11 extending upwardly beside the strap, the ears 12 extending downwardly from the socket 6, and the pin 13 connecting said ears 12 to the ear 9.

707,289. LONG-WAIST FORMER. JAMES C. KIMBEY, Philadelphia, Pa. Filed Nov. 6, 1901. Serial No. 81,223. (No model.)

Claim.—1. As an improved article of manufacture, a long-waist former, comprising a plate having means for attaching the same to a corset or other garment, V-shaped slots in the sides of the plate, and a cord attached to the lower end of the plate, substantially as shown and described.

2. As an improved article of manufacture, a long-waist former, comprising a plate having means for attaching the same to a corset or other garment, a hook at the lower end of the plate, V-shaped slots in the sides of said plate, and a cord attached to the lower end of the plate, substantially as shown and described.

3. As an improved article of manufacture, a long-waist former, comprising a plate having means for attaching the same to a corset or other garment, a hook at the lower end of the plate, a cross-bar, and a cord in looped engagement with the cross-bar, substantially as shown and described.

4. As an improved article of manufacture, a long-waist former, comprising a plate having means for attaching the same to a corset or other garment, a hook and cross-bar at the lower end of the plate, and V-shaped slots in the sides of the plate; together with a cord in looped engagement with the cross-bar, substantially as shown and for the purpose set forth.

5. As an improved article of manufacture, a long-waist former, comprising a plate provided with means of attaching the same to a corset or other garment, a hook stamped from the lower end of the plate, a cross-bar below the hook, and spring members at the sides of the plate curved forwardly to provide V-shaped slots or openings; together with a cord or tape attached to the cross-bar, substantially as shown and for the purpose set forth.

6. As an improved article of manufacture, a long-waist former, comprising a plate having keyhole-slots in its upper end, a hook at its lower end, and V-shaped slots in its sides; together with a cord attached to the lower end of the plate, substantially as shown and described.

707,240. SHADE ADJUSTMENT. FRED H. KNAPP, Chicago, Ill. Filed Nov. 16, 1901. Serial No. 82,550. (No model.)

Claim.—1. In a device of the character described, a shade provided at one end with suitable actuating means, vertical guide-rods, and guiding means for the free portion of the shade, comprising slides on said rods, and slide-supporting means on said shade near the free end thereof and engaging said slides, the slide and slide-supporting means of each set being capable of relative movement in a plane parallel with the shade, substantially as described.

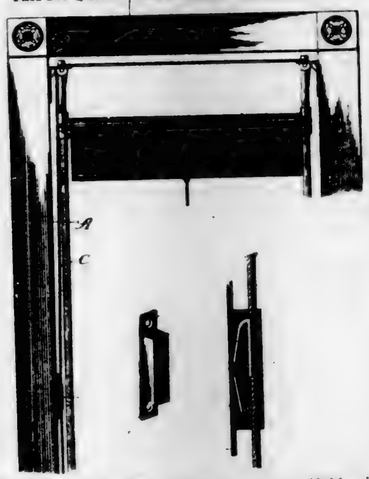
2. In a device of the character described, a shade provided at one end with suitable actuating means, vertical guide-rods, and guiding means for the free portion of the shade, comprising slides on said rods, and slide-supporting means on said shade near the free end thereof and engaging said slides, one of said last-named parts of each set bearing a pivoted tongue and the other a recess for receiving said tongue, substantially as described.

3. In a device of the character described, a shade suitably attached at one end, guide-rods, and guiding means for the free part of the shade, comprising slide-supporting members connected with said shade, and having suitable recesses, and slides on said guide-rods provided with pivoted tongues engaging said recesses, substantially as described.

4. In a device of the character described, a shade provided at one end with suitable actuating means and at the opposite end with a binding member, clips connected with said shade at said binding member and forming sockets beneath said member, guide-rods, and slides on said rods having projections engaging said sockets, substantially as described.

5. In a device of the character described, the combination of vertical guide-rods, roll-supporting slides connected therewith, a roll supported from said slides, and bearing a shade, slides connected with said rods and with the shade near its free end, fixed slide-stops intermediate said first-named slides and said second-named slides, and means for actuating said roll-supporting slides, whereby the roll may be raised and the shade drawn at one operation, substantially as and for the purpose set forth.

707,241. CORD-HOLDING DEVICE. FRED H. KNAPP, Chicago, Ill. Filed Dec. 4, 1901. Serial No. 84,648. (No model.)



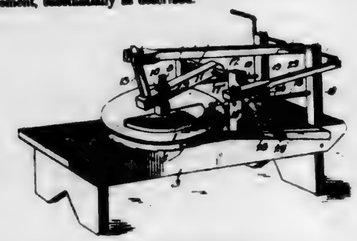
Claim.—1. In combination, a hollow member provided interiorly at one side with a spring-retainer, an unattached spring having ends turned toward the wall supplied with said retainer, and a cord confined between said spring and the opposed wall of said first-named member.

2. In combination, a tube of rectangular cross section provided with suitable attaching means and having one wall cut transversely on two lines and the intermediate portion bent inwardly to afford a retainer, and a spring having its two ends bent to engage said retainer and its intermediate portion serving to engage a cord, substantially as described.

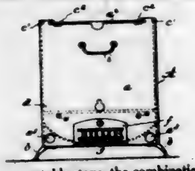
3. In combination, a hollow member provided interiorly at one side with a spring-retainer, an unattached spring having convergent ends turned toward the wall supplied with said retainer and a back supplied with a longitudinal groove, and a cord confined in said groove between said spring and the opposed wall of said first-named member, substantially as and for the purpose set forth.

707,242. WASHING-MACHINE. JAMES M. LAWRENCE, Commerce, Tex. Filed Sept. 12, 1901. Serial No. 75,217. (No model.)

Claim.—A washing-machine comprising a frame having open bearings, a rotary table mounted on the frame and provided at its lower face with teeth, an oscillatory lever arranged centrally of the frame and located above the rotary table, a pounder carried by the lever, a transverse crank-shaft removably arranged in the open bearings and connected with the said lever, an upright lever arranged at one side of the machine and fulcrumed between its ends, a connecting-bar extending from the upper arm of the upright lever to the crank-shaft, and an actuating-pawl pivoted between its ends on the lower arm of the upright lever and wholly supported by the same, said pawl engaging the teeth of the table at one end and having its other arm weighted, the weighted arm holding the pawl in its engaging position and being also adapted to hold the pawl out of engagement, substantially as described.



707,248. PORTABLE STOVE. EVA C. LEONARD, Thompson, Pa. Filed Apr. 24, 1902. Serial No. 104,494. (No model.)

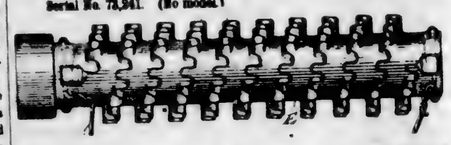


Claim.—1. In a portable stove, the combination, of the sheet-metal body A, having a sliding top, and the bottom curved up at the corners of the front, a perforated plate forming the grate, rods supporting the grate and bearing at their ends in the walls of the body of the stove, and a door in the front provided with a damper, the said stove being supported upon feet, substantially as shown and described.

2. In a portable stove, the combination, of the body A made up of sheet metal and having a bottom curved upward at its front corners, a sliding plate forming the top of the stove, a perforated plate forming the grate and supported upon rods extending from the front to the rear, one of the rods being located away from the adjoining side, and a door covering an opening in the front, said door having a sliding damper and inwardly-projecting flanges, substantially as shown and described.

3. In a portable stove, the combination, of the body A, made up of sheet metal and rectangular in cross-section, a bottom curved upward at its front corners, openings through the body of the stove below said curved corners, the sides of the body of the stove being turned into beads reinforced by wires which rest upon the front and back, and said sides extended to provide the flanges, and a sliding top supported upon said flanges; together with a door in the front of the stove having flanges and a damper, the said stove being provided with supporting-feet, and with handles, as shown and described.

707,244. RESISTANCE FOR RHEOSTATS, ELECTRIC HEATERS, &c. HARRY W. LEONARD, Bronxville, N. Y. Filed Aug. 28, 1901. Serial No. 73,241. (No model.)



Claim.—1. As a new article of manufacture, a metallic electrical conductor in the form of a ribbon arranged edgewise under tension around an electrical insulating-surface capable of withstanding heat.

2. As a new article of manufacture, a metallic electrical conductor in the form of a reflexed ribbon arranged edgewise under tension around an electrical insulating-surface capable of withstanding heat.

3. As a new article of manufacture, a metallic electrical conductor in the form of a ribbon wound edgewise around an electrical insulating-surface capable of withstanding heat.

4. As a new article of manufacture, a metallic electrical conductor

in the form of a ribbon wound edgewise under tension around an electrical insulating-surface capable of withstanding heat.

5. As a new article of manufacture, a metallic electrical conductor in the form of a reflexed ribbon wound edgewise under tension around an electrical insulating-surface capable of withstanding heat.

6. As a new article of manufacture, a metallic electrical conductor in the form of a ribbon arranged edgewise under tension around a cylindrical electrical insulating-surface capable of withstanding heat.

7. As a new article of manufacture, a metallic electrical conductor in the form of a reflexed ribbon arranged edgewise under tension around a cylindrical electrical insulating-surface capable of withstanding heat.

8. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the support as to materially change its position thereon.

9. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the support as to materially change its position thereon.

10. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise around a cylindrical electrical insulating-surface capable of withstanding heat, and said conductor being secured to said surface by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on said surface as to materially change its position thereon.

11. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise around a cylindrical electrical insulating-surface capable of withstanding heat, and said conductor being secured to said surface by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on said surface as to materially change its position thereon.

12. As a new article of manufacture, a metallic-ribbon conductor wound edgewise upon a support of mineral insulating material and provided with one or more terminals or leads, said conductor being secured to the support by means of a vitreous glass.

13. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a support of mineral insulating material, and having one or more terminals or leads, and metal clamping-plates for maintaining electrical connection between the conductor and each lead, said conductor being secured to the support by means of a vitreous glass.

14. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a tubular support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass.

15. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a pottery-tube, said conductor being secured to the tube by means of a vitreous glass.

16. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a tubular support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass.

17. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a pottery-tube, said conductor being secured to the tube by means of a vitreous glass.

18. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a tubular support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the support as to materially change its position thereon.

19. As a new article of manufacture, a metallic-ribbon conductor arranged edgewise upon a pottery-tube, said conductor being secured to the tube by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the tube as to materially change its position thereon.

20. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise on a tubular support of mineral insulating material, said conductor being secured to the support by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the support as to materially change its position thereon.

21. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a pottery-tube, said conductor being secured to the tube by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the support as to materially change its position thereon.

22. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a pottery-tube, and provided with one or more terminals or leads, said conductor being secured to the tube by means of a vitreous glass having a fusing-point so low that it fuses before the conductor becomes so loose on the tube as to materially change its position thereon.

23. As a new article of manufacture, a metallic-reflexed-ribbon conductor arranged edgewise upon a pottery-tube, and having one or more terminals or leads, and metal clamping-plates for maintaining electrical connection between the conductor and each lead, said conductor being secured to the tube by means of a vitreous glaze having a fusing-point so low that it fuses before the conductor becomes so loose on the tube as to materially change its position thereon.

24. As a new article of manufacture, two or more metallic conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze.

25. As a new article of manufacture, two or more metallic-ribbon conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze.

26. As a new article of manufacture, two or more metallic-reflexed-ribbon conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze.

27. As a new article of manufacture, two or more metallic conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze of low fusing-point.

28. As a new article of manufacture, two or more metallic-ribbon conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze of low fusing-point.

29. As a new article of manufacture, two or more metallic-reflexed-ribbon conductors arranged in multiple between terminal leads upon a support of mineral insulating material, said conductors being secured to the support by means of a vitreous glaze of low fusing-point.

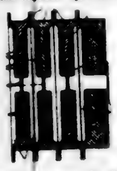
30. As a new article of manufacture, two or more metallic conductors arranged in multiple between terminal leads under tension upon an electrical insulating-surface.

31. As a new article of manufacture, two or more metallic conductors arranged in multiple between the terminal leads under tension upon a cylindrical electrical insulating-surface.

32. As a new article of manufacture, two or more metallic conductors wound like a double thread in multiple between terminal leads under tension upon an electrical insulating-surface.

33. As a new article of manufacture, two or more metallic conductors wound like a double thread in multiple between terminal leads under tension upon a cylindrical electrical insulating-surface.

707,245. FILTER-PRESS. FRED M. LOCKE, Victor, N. Y. Filed May 17, 1901. Serial No. 60,709. (No model.)



Claim.—1. A plate for filter-presses having a yielding bearing-surface made of absorbent material for engaging the sacks and preventing injury thereto, and permitting escape of the water.

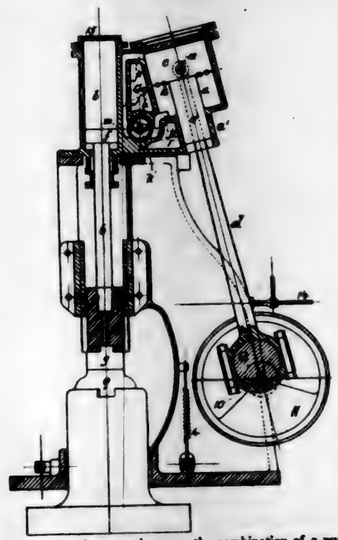
2. In combination with a filter-press plate having a corrugated surface, a yielding disk adjacent to the corrugated surface for preventing injury to the sack, said disk being made of absorbent material, for permitting easy outlet for the water.

3. The combination with the plates and bags of a filter-press of layers of absorbent material between the bags and plates for taking up the liquid and conducting the same from the material to be treated.

707,246. PNEUMATIC POWER-HAMMER. HAROLD F. MABEY, Withington, England. Filed Mar. 1, 1901. Serial No. 49,384. (No model.)

Claim.—1. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders.

2. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and means to open such openings more or less and close them.



3. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

4. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders, a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction and a valve provided in connection with the other of the said passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

5. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings.

6. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders a passage connecting the said openings and means to close or open more or less the said passage and so the said openings.

7. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings and a valve to close or open more or less the said passage and so the said openings.

8. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a valve provided in connection with the said passage to close or open it more or less and so to close or open more or less the said openings, and a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

9. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a valve provided in connection with the said passage to close or open it more or less and so to close or open more or less the said openings, a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction and a valve provided in connection with the other of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

10. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a valve provided in connection with the said passage to close or open it more or less and so to close or open more or less the said openings, and a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

11. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a valve provided in connection with the said passage to close or open it more or less and so to close or open more or less the said openings, a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction and a valve provided in connection with the other of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

12. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a valve provided in connection with the said passage to close or open it more or less and so to close or open more or less the said openings, a valve provided in connection with the said passage to stop at times the flow of air therethrough in one direction, a valve provided in connection with one of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction, and a valve provided in connection with the other of the passages connecting the said cylinders to stop at times the flow of air therethrough in one direction.

13. In a pneumatic power-hammer the combination of a pump-cylinder and a hammer-cylinder with passages to connect the two ends of the one with the two ends of the other and furnished with openings to be opened more or less or closed in order to regulate the flow of air between such cylinders and a passage connecting the said openings, a plug provided with a valve to close or open more or less the said passage and so the said openings and a valve carried on the said plug and so inserted at times into the said passage to stop the passage of air therethrough in one direction and a second valve carried on the said plug and so inserted at times into one of the passages connecting the said cylinders to stop the flow of air therethrough in one direction.

14. In a pneumatic power-hammer having a pump-cylinder and a hammer-cylinder the combination with the hammer-cylinder of a cover provided with a cavity forming an extension of the interior of the said hammer-cylinder and made to fit the piston working in the said hammer-cylinder for the purposes hereinbefore described.

15. In a pneumatic power-hammer provided with valves the combination with such valves and the means employed to operate them of an elastic connection in the said means and a catch on part thereof and a catch which is movable upon a fixed part and provided with means to engage a moving part of the hammer and being moved thereby disengage the catches and permit the movement of said valves for the purposes hereinbefore described.

707,247. PLANT-PROTECTOR. LEONARD J. MERRIHAN, Ivanhoe, N. C. Filed Aug. 19, 1901. Serial No. 72,465. (No model.)

2. A plant-protector comprising a series of stiff or rigid lapping sections, and means located at a predetermined one of the series whereby the whole number thereof are operated to be raised or lowered together.

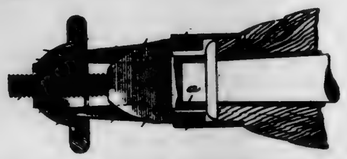
3. The combination of a plurality of plant-protectors having transversely-curved rigid bodies lying parallel with each other, a reciprocatable bar lying transversely above them, and a series of crossed pairs of flexible connections extending diagonally from the bar to the protectors severally connecting the same relative lower edges of the latter to the bar, so that reciprocation of the latter effects either the raising or lowering of the connected edges of the protectors substantially as and for the purpose set forth.

4. A plant-protector comprising a series of stiff or rigid lapping sections, and means connecting the overlapping end sections of a series whereby all the end sections of a series may be raised or lowered simultaneously.

5. A plant-protector comprising one or more sections movably anchored in the ground at one edge and provided with eyes at the sides thereof near the lower edge, wires or cords connecting with said eyes and crossing each other at the top of said sections, and a movable operating-bar to which the ends of the wires are connected.

6. A plurality of series of plant-protectors, each series being composed of veneer sections comprising bodies having successively overlapping ends, the first member of each series having eyes located near its edge on opposite sides; a raising means passing over said plurality of series; and flexible crossed means connecting said eyes to said means.

707,248. AXLE-NUT WRENCH. Robert A. Moody, Solsus, Ind. Filed Aug. 10, 1901. Renewed May 3, 1902. Serial No. 105,822. (No model.)



Claim.—1. In a wrench of the kind described, the combination of a socket portion having one end terminating in a threaded shank, clamping-jaws pivoted to the said socket portion, and a hand-wheel nut adapted for engagement with the jaws, substantially as shown and described.

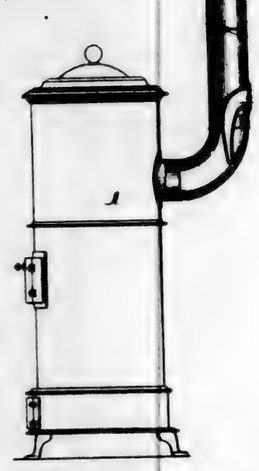
2. In a wrench of the kind described, the combination of a socket portion having a threaded shank formed integral therewith, and a rectangular recess formed therein, clamping-jaws pivoted upon opposite sides of the said socket portion, a hand-wheel nut having its hub provided with a tapering annular recess and adapted for engagement with the clamping-jaws, substantially as shown and described.

3. In a wrench of the kind described the combination of a socket portion having a rectangular recess produced in one end and a threaded shank protruding from the opposite end thereof, ears formed on the said socket portion, clamping-jaws pivoted in the said ears, the heads of said jaws having their outer surfaces convexed and serrated, and the shanks thereof extending past the end of the said socket portion, a hand-wheel hub adapted to operate on the said threaded shank, the hub thereof having a tapering annular recess, the inner surface of which being adapted for engagement with the shanks of the said clamping-jaws, substantially as shown and described.

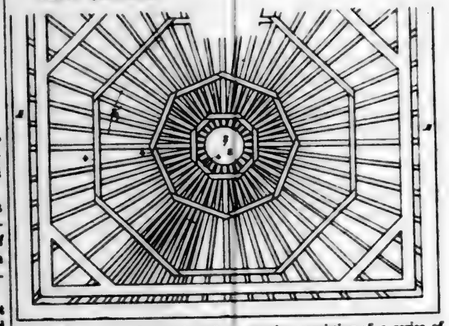
707,249. APPARATUS FOR INCREASING COMBUSTION IN FURNACES. James H. McConnell, Evanston, Ill. Filed Feb. 24, 1902. Serial No. 95,295. (No model.)

Claim.—1. The combination with the combustion-chamber of a furnace and with a smoke pipe or flue leading therefrom, said smoke pipe or flue having an opening in its wall and having a damper located above said opening, of an open-ended unobstructed air-delivery pipe extending inwardly and downwardly from said opening and away from the wall of the smoke-flue, whereby said pipe shall be surrounded by outgoing products of combustion, said pipe terminating adjacent to but outside the combustion-chamber and adjacent that part of the wall of the smoke-flue farthest from the direct path of the outgoing products of combustion.

2. The combination with the combustion-chamber of a furnace and with a smoke pipe or flue leading therefrom, said smoke pipe or flue having an opening in its wall and having a damper located above said opening, of an air-delivery pipe extending inwardly and downwardly from said opening whereby said pipe shall be surrounded by outgoing products



707,250. ROOF, CEILING, AND FLOOR CONSTRUCTION. Barnett McDougall, San Francisco, Cal. Filed Feb. 19, 1902. Serial No. 94,810. (No model.)



Claim.—1. A floor and roof construction consisting of a series of joists or bars radiating from a common center, said bars or joists unsupported except at their outer ends, and concentric bands or rings engaging said bars or joists and uniting them into a rigid structure.

2. A floor and roof construction consisting of a series of joists or bars radiating from a common center, said bars or joists supported only at their outer ends, concentric polygonal bands secured to said bars or joists and uniting them into a rigid structure.

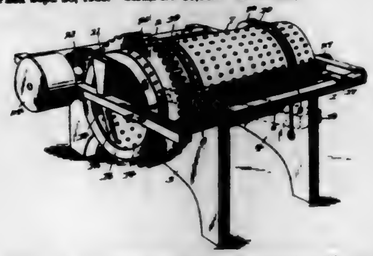
3. A floor and roof structure consisting of a series of joists or bars radiating from a common center, and a plurality of concentric, polygonal bands secured to and uniting said joists or bars, said bands lying in break-joint courses.

4. A floor and roof structure consisting of a series of joists or bars radially disposed in relation to a common center, the contiguous ends of said joists inclosing a central opening, a curbing of steel or like suitable material against which the said contiguous ends abut, and a plurality of concentric binding rings or bands.

5. A floor and roof structure consisting of a series of joists or bars radially disposed in relation to a common center, each of said joists comprising a plurality of superposed strips or plates lying in the same vertical plane, concentric bands or rings alternately disposed between said strip and means whereby the rings and strips are rigidly united.

6. A floor and roof structure consisting of a series of joists radially disposed in relation to a common center, each of said joists composed of a plurality of superposed, interposed strips or plates, concentric bands or rings in the spaces between said strips, and said strips and interlocking bands or rings rigidly secured together.

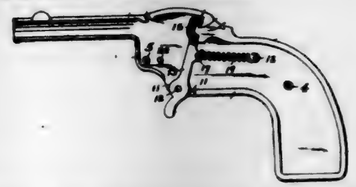
707,251. GRAIN-SEPARATOR. Christian Otto, Hastings, Pa. Filed Sept. 30, 1899. Serial No. 732,457. (No model.)



Claim.—1. In combination with a frame, supporting-rollers mounted thereon for revolution and having annular peripheral grooves, a revolvable cylinder supported on said rollers and having annular peripheral track-ribs engaging the grooves in the rollers, and curved rods secured to the frame, arched over and bearing on the cylinder, said rods preventing the cylinder from moving from the rollers and coacting with the respectively ribbed and grooved cylinder and rollers to prevent longitudinal movement of the cylinder on the rollers, substantially as described.

2. The combination of a frame, supporting-rollers mounted thereon for revolution and having annular peripheral grooves, a revolvable cylinder supported on said rollers and having annular peripheral track-ribs engaging the grooves in the rollers, curved rods secured to the frame, arched over and bearing on the cylinder to prevent the latter from moving from the rollers and to coact with the respectively ribbed and grooved cylinder and rollers to prevent longitudinal movement of the former on the latter, a gear 20 on said cylinder, a power-shaft 22 having its bearings on said frame and provided with a pinion engaging said gear, a pulley 25 on said power-shaft, a fixed cockle-receiving trough extending longitudinally through the cylinder at one side thereof, a revolvable conveying-screw in said trough, having a shaft journaled in bearings in the frame and provided with a pulley 27, and an endless belt connecting said pulleys 25, 27, substantially as described.

707,252. TOY PISTOL. Charles F. Parker, Newark, N. J. Filed Dec. 18, 1901. Serial No. 86,402. (No model.)



Claim.—1. In a toy pistol, the combination, with a chambered pistol-frame having an opening in its upper surface through which a cap can be inserted, of a pivoted hammer within said pistol-frame, provided in its upper portion with a cap-receiving part, adapted to register with the said cap-inserting opening in the pistol-frame, and means within said pistol-frame against which said cap-receiving part is brought for exploding the cap, substantially as and for the purposes set forth.

2. In a toy pistol, the combination, with a chambered pistol-frame having an opening in its upper surface through which a cap can be inserted, of a firing-anvil and a firing-pin on said anvil, both said anvil and firing-pin being arranged within said pistol-frame, a pivoted hammer within said frame, a cap-receiving part upon the upper portion of said hammer, said cap-receiving part having a hole or perforation, and the said cap-receiving part being adapted to register, first, with the said cap-inserting opening in the upper surface of the pistol-frame, and, secondly, with the firing-pin on said anvil for the explosion of the cap, substantially as and for the purposes set forth.

707,253. CAN-OPENER. James W. Pierce, Bolton, Tex. Filed Nov. 20, 1901. Serial No. 83,051. (No model.)

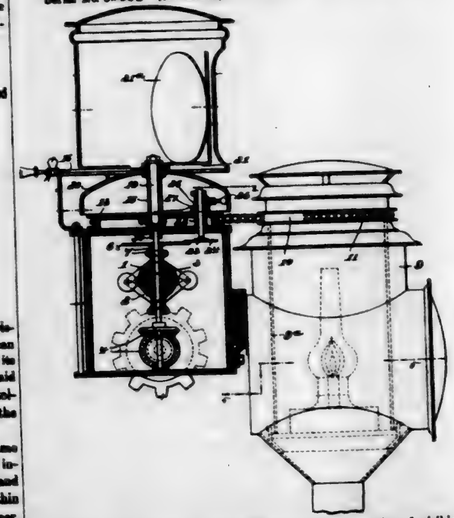
Claim.—1. A can-opener, comprising a pointed stem, a freely-reciprocatory weighted driving-handle slidably mounted upon the stem, a stop engagement between the stem and the handle to limit the inward movement of the latter, and a cutter carried by the handle.

2. A can-opener, comprising a pointed stem having a longitudinal slot or groove, a freely-reciprocatory weighted driving-handle slidably mounted upon the stem and having a projection working in the slot or groove for contact with the opposite ends thereof, and a cutter carried by the handle.

3. A can-opener, comprising a stem provided at its outer end with a hooked pointed terminal, and also having an intermediate longitudinal groove or slot, a hollow metallic handle slidably mounted upon the stem, and provided with a transverse pin working in the slot or groove and adapted to engage the opposite ends thereof, the inner end of the handle being reduced, and a rotatable cutting-disk mounted upon the reduced inner end of the handle, the outer end of the reduced portion of the handle being upset to prevent displacement of the disk.

4. A can-opener, having weighted freely-reciprocatory means working upon the stem thereof and forming a driving-handle to drive the point of the stem into a can.

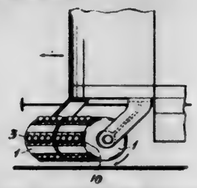
707,254. APPARATUS FOR INDICATING WHEN CERTAIN PREDETERMINED SPEEDS ARE EXCEEDED BY VEHICLES. Auguste F. Poillevillain dit P. Villain, Paris, France. Filed May 10, 1901. Serial No. 59,554. (No model.)



Claim.—In a device of the character described, a series of visible signals adapted to be displayed singly to indicate visually the limit of speed of the vehicle, a hand-lever adapted to set said visible signals, a governor controlled by the speed of the vehicle, a disk adapted to be rotated and to be elevated and depressed by the governor, an audible signal, a spin-

dle adapted when rotated to operate said audible signal, a disk carried by said spindle and arranged adjacent to the governor-disk and means controlled by the movement of the hand-lever for varying the distance between the two disks independently of the up-and-down movement of the governor-disk.

707,255. SAFETY-RAIL FOR TRAM PROTECTING-ROLLERS. EMANUEL RAHN, Prague, Austria-Hungary. Filed Apr. 30, 1902. Serial No. 105,319. (No model.)



Claim.—1. The combination with tramway protecting-rollers having undercut or dovetailed longitudinal grooves, of elastic balls or fingers 3 having rectangular soles with beveled longitudinal edges engaging the longitudinal grooves in the periphery of said rollers, substantially and for the purpose as set forth.

2. The combination with tramway protecting-rollers, having undercut or dovetailed longitudinal grooves, of elastic balls or fingers having rectangular soles, with beveled longitudinal edges, engaging said longitudinal grooves, and bands 9 encircling the rollers and clamping over the projecting ends of said soles in the annular spaces between the balls.

3. The combination with tramway protecting-rollers having undercut or dovetailed longitudinal grooves, of elastic balls or fingers having rectangular soles, with beveled longitudinal edges, engaging said longitudinal grooves, bands 9 encircling the rollers in the annular spaces between the balls and above the projecting ends of said soles and bars 10 attached to the car-frame and embracing said bands.

707,256. SWINGING GATE. JOHN W. REAMES and CALVIN F. HEFFINGTON, Corley, Ark. Filed Apr. 24, 1902. Serial No. 104,531. (No model.)

Claim.—1. In a swinging gate, the combination with suitable keepers located in line with the gate in its closed position and on opposite sides of the gate; of suitable operating means and connections whereby the gate may be swung in either direction to an open or closed position from either side of the gateway, a gravity-latch upon the gate to engage the keepers, a spring-arm connected with the latch, and a cam movable with the gate and adapted to push back the spring-arm to effect the disengagement of the latch, said cam having recesses in which the arm may seat itself at proper times to allow the latch to move into engagement with the keepers, substantially as specified.

2. In a swinging gate, the combination with suitable keepers located in line with the gate in its closed position and on opposite sides of the gate; of suitable operating means and connections, whereby the gate may be swung in either direction to an open or closed position from either side of the gateway, a pivoted L-shaped latch-lever mounted upon the gate and having one of its arms forming a latch to engage the keepers, a spring-arm, a connection between the spring-arm and other arm of the lever, and a cam movable with the gate and adapted to push back the spring-arm to effect the disengagement of the latch, said cam having recesses in which the arm may seat itself at proper times to allow the latch to move into engagement with the keepers, substantially as and for the purpose described.

707,257. RAIL-FASTENER. CALVIN M. REED, Shrewsbury, Pa. Filed Dec. 27, 1901. Serial No. 87,478. (No model.)

Claim.—1. A railway-tie comprising two arched metallic beams superposed the one upon the other, means carried by said beams for grasping the opposite edges of the flanges of the rails, and means for locking said beams against endwise movement relatively one to the other, substantially as described.

2. A railway-tie comprising two arched metallic beams superposed one upon the other, each provided on their opposite edges with depending and flaring flanges, tongues struck up from the upper sides of said beams and arranged to grasp the opposite edges of the flanges of the rails, and means for preventing the endwise movement of said beams relatively to one another, substantially as described.

3. A metallic railway-tie comprising two sheet-metal beams superposed one upon the other, each consisting of a flat body portion provided on its opposite edges with depending and flaring flanges, each of said beams being provided on its upper side with upwardly and horizontally projecting tongues, the tongues of each beam extending in the same direction, and the tongues of one beam extending in an opposite direction to the tongues of the other beam to grasp the opposite sides of the flanges of the rails, and means for locking said beams against endwise movement relatively one to the other substantially as described.

4. A railway-tie comprising two sheet-metal beams superposed the one upon the other, each consisting of a flat body portion provided on its opposite sides with depending and outwardly-flaring flanges, each of said beams being provided near its opposite ends with rectangular slits, the metal between said slits being struck up to form upwardly and horizontally projecting tongues, the tongues of one beam extending in a direction opposite to the tongues of the other beam to grasp between them the opposite edges of the flanges of the rails, and the tongues of the lower beam projecting through the slots of the upper beam, and means for locking said beams against endwise movement relatively one to the other substantially as described.

5. A railway-tie comprising two sheet-metal beams superposed the one upon the other, and each consisting of a flat body portion provided on its opposite sides with depending flanges, said beams being provided with upwardly and horizontally projecting tongues arranged to grasp between them the opposite edges of the flange of the rails, the depending flanges of the under beams being provided with inwardly-projecting anchor-plates to prevent longitudinal movement of the tie in the road-bed substantially as described.

6. A railway-tie comprising two sheet-metal beams superposed the one upon the other, each consisting of a flat body portion provided on its opposite edges with depending flanges, tongues carried by said beams for grasping between them the opposite edges of the flanges of the rails, means for locking said beams against endwise movement relatively one to the other, the flanges of the under beam being vertically slitted, and the metal on one side of each slit being bent inward to form an anchor-plate to hold the tie against endwise movement in the road-bed substantially as described.

7. A railway-tie comprising two arched sheet-metal beams slidably superposed the one upon the other, said beams being provided with upwardly and horizontally projecting tongues, the tongues of one beam being disposed in the opposite direction to the tongues of the other beam to grasp the opposite edges of the flanges of the rail between them, each of said beams being provided at one end with a bolt-hole, said bolt-holes being arranged to register when the beams are in position to hold the rails thereto, and a bolt passing through said bolt-holes, and operating to hold said beams against endwise movement relatively one to the other, substantially as described.

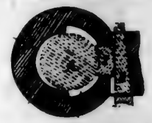
707,258. LEG-IMPROVER. HARRY A. RHODENUS, Springfield, Ohio, assignor to S. F. Rhodenus, Springfield, Ohio. Filed Mar. 13, 1902. Serial No. 98,023. (No model.)

Claim.—1. A leg-improver consisting of an elongated concave-convex sheet of substantially rigid material, straight longitudinally, and extending along the side of the leg from a point slightly above or in line with the knee to a point below the same, being shaped to fit against the side of the lower leg and extend over the hollow at the side of the knee, and means for securing the same to the leg, substantially as described.

2. A leg-improver consisting of an apertured, elongated, concave-convex sheet of substantially rigid material, straight longitudinally, extending along the side of the leg from a point slightly above or in line with the knee to a point below the same, and provided with an aperture, being shaped to fit against the side of the lower leg and extend over the hollow at the side of the knee, and a retaining device consisting of a flexible band or garter connected with said apertured sheet and fastening around the leg, substantially as described.

3. A leg-improver consisting of an apertured, elongated, concave-convex sheet of substantially rigid material, straight longitudinally, extending along the side of the leg from a point slightly above or in line with the knee to a point below the same, and provided with an aperture near its top, its lower end being adapted to be inserted between the sock and leg, and a retaining device consisting of a flexible band or garter connected with said apertured sheet, fastening around the leg, and having a depending portion to engage and support the sock, substantially as described.

707,259. STAMP-TAPPET. CHARLES C. RUSSER, Butte, Mont. Filed June 5, 1901. Serial No. 63,242. (No model.)



Claim.—1. A stamp-stem tappet adapted to receive independent and separated gibs and keys upon one side, and having the bore opposite the gibs of less, and the bore upon the side adjacent to the keys of greater diameter than that of the stamp-stem upon which the tappet is fitted.

2. A stamp-tappet having a bore longitudinally through it approximately half of said bore being of such radius as to fit tightly about the stem, and the other and opposite portion of the bore having a larger diameter to form a clearance between itself and the stem, keyways passing through the tappet at two or more points removed from each other upon the side contiguous to the larger bore, and gibs and keys by which the smaller part of the bore is caused to seat about the stamp-stem.

3. A stamp-tappet having a longitudinal bore of two different radii, the smaller of which is adapted to seat tightly around the stamp-stem, openings made transversely through the tappet upon the opposite side, gibs fitting said openings, and occupying portions only of the clearance-space formed by the larger bore, and seating against the stamp-stem, and independent keys for each gib adapted to lock them in position.

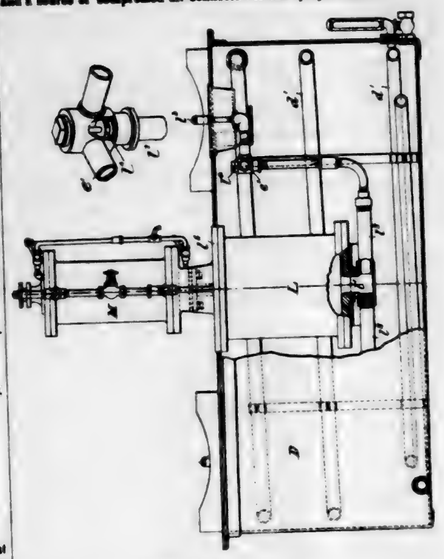
4. A stamp-tappet having a longitudinal bore, one portion of which is of smaller radius than that of the stamp-stem, and the opposite portion of larger radius, independent gibs and chambers removed from each other and into which they fit in the portion opposite the smaller portion of the bore, keys bearing on approximately the entire back surface of the gibs, and keyways through which they are driven to force the gibs against the stem and seat the latter in the opposing smaller bore of the tappet.

707,260. APPARATUS FOR LINING CASKS, BARRELS, OR LIKE VESSELS. HERBERT S. RUSSELL, London, England. Filed Aug. 23, 1900. Serial No. 27,862. (No model.)

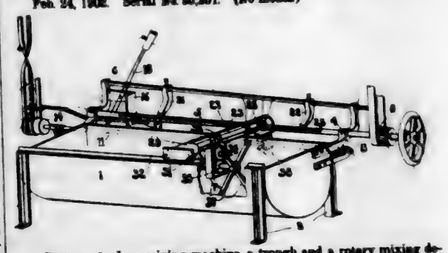
Claim.—1. In an apparatus for lining casks, barrels and the like, the combination of a tank for the lining material, a cylinder inclosed by the tank, a plunger working in said cylinder, a valve in said cylinder opening inward, an outlet-pipe leading from the cylinder and provided with a spray-nozzle at its outer end, a back-pressure valve in the outlet-pipe, a source of compressed air, a pipe forming communication between said source and said outlet-pipe, and a back-pressure valve in said pipe.

2. In an apparatus for lining casks, barrels and the like, the combination of a tank for the lining material, a heating-coil in said tank, a cylinder within the tank, a plunger working in the cylinder, an inwardly-opening valve in the cylinder, an outlet-pipe leading from the cylinder, and having a spray-nozzle at its outer end, a back-pressure valve in the outlet-pipe to prevent the return of the lining material, a source of compressed air, a pipe leading from said source to the outlet-pipe between the back-pressure valve and the nozzle, and a back-pressure valve in the connecting-pipe.

3. In an apparatus for lining casks, barrels and the like, the combination of a tank for the lining material, means to heat the same, a pump within said tank, a spray-nozzle in connection with said pump, whereby the liquid is conveyed from the tank by the pump to the spray-nozzle and a source of compressed air connected to the spray-nozzle.



707,261. MIXING-MACHINE. ERNEST RUTTKAMP, Allegheny, Pa., assignor of one-half to Charles Ruttkamp, Allegheny, Pa. Filed Feb. 24, 1902. Serial No. 95,201. (No model.)



Claim.—1. In a mixing-machine, a trough and a rotary mixing device having relative longitudinal movement, and means for reversing said movement, said device being capable of removal by oscillation from over said trough.

2. In a mixing-machine, a trough and a rotary mixing device having relative longitudinal movement, and means for reversing said movement, said device being removable from over said trough by oscillation on an axis substantially parallel to the line of said longitudinal movement.

3. In a mixing-machine, a trough and rotary mixing-blades having relative longitudinal movement, a shaft for producing the longitudinal movement, a shaft external to the trough for rotating the blades, and means supporting the blades and slidable on the latter shaft.

4. In a mixing-machine, a trough, a carriage provided with rotary mixing blades and having longitudinal and vertical movements, and means for reversing the longitudinal movement.

5. In a mixing-machine, a trough, a carriage provided with rotary mixing-blades and having longitudinal and vertical movements, and automatic means for reversing the longitudinal movement.

6. In a mixing-machine, a trough and rotary mixing-blades having relative longitudinal movement, said blades being capable of removal from over the trough and any selected point therein rotating transversely of the line of said longitudinal movement.

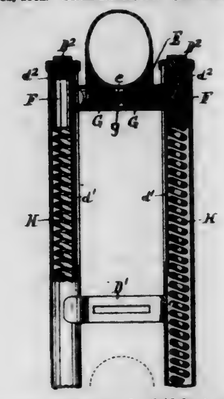
7. In a mixing-machine, a trough, a carriage provided with mixing-blades, a driving-shaft, driving connections between said shaft and blades permitting the travel of the carriage on said shaft, a rotatable screw-shaft, a nut in said carriage to receive the screw-shaft, and means controlled by the carriage for reversing the rotation of the screw-shaft.

9. In a mixing-machine, a trough, a carriage provided with mixing-blades, a driving-shaft, driving connections between the shaft and the blades, permitting the travel of the carriage on said shaft, a second driving-shaft, connections between the latter and the carriage for causing travel of the carriage, and means for automatically reversing the rotation of the second driving-shaft.

9. In a mixing-machine, a trough, a carriage provided with mixing-blades and having longitudinal travel over said trough, a driving-shaft, a bevel-gear splined on the shaft, a second shaft mounted on the carriage and having a bevel-gear meshing with the splined gear, a worm on the second shaft, and gearing between the worm and the blades for driving the latter.

10. In a mixing-machine, a trough, a carriage provided with mixing-blades, means for driving the carriage, a sliding bar, stops on the bar, connections from said bar for reversing the movement of the carriage, and an overthrow-lever associated with the bar.

707,262. CUSHION-FRAME FOR BICYCLES OR LIKE VEHICLES. JAMES H. SAGER and GEORGE D. GREEN, Rochester, N. Y. Filed Jan. 13, 1902. Serial No. 89,266. (No model.)



Claim.—1. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; tubular rear braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; a cross-bar flexibly connected with the front frame and passing through said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

2. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; parallel tubular braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; a cross-bar flexibly connected with the front frame and passing through said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

3. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; tubular rear braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; an adjustable cross-bar flexibly connected with the front frame and passing through said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

4. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; tubular rear braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; a separable cross-bar flexibly connected with the front frame and passing through said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

5. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; tubular rear braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; a bracket rigidly connected with the front frame; an adjustable cross-bar revolubly supported within said bracket and entering said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

6. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; tubular rear braces flexibly connected with said fork; a slot in each of said braces at its upper end; a spring within each of said braces; a seat for the bottom of each of said springs; a bracket rigidly connected with the front frame; a separable cross-bar revolubly supported within said bracket and entering said slots; a block within each of said braces resting on the spring in the brace and secured to said bar and free to slide within said brace; and a stop in each brace above the block.

7. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; the tubular braces D, D, flexibly connected with said fork and having respectively longitudinal slots d', d'; the bracket E; blocks F, F, free to slide within said braces; arms G, G, rotatively secured within said bracket and attached to said blocks; springs H, H, inclosed within said braces respectively and a stop in each brace above the block, substantially as shown and described.

8. The combination of a rigid front section; a rear-wheel fork flexibly connected therewith at the crank-hanger; the parallel tubular braces D, D, flexibly connected with said fork and having respectively longitudinal slots d', d', the caps D^2, D^2, in the top of said tubular braces, the bracket E rigidly secured to the front section; arms G, G, rotatively secured within said bracket; the screw g for adjustably connecting said bars; blocks F, F, free to slide within said braces; springs H, H, within said braces, and seats for said springs respectively, substantially as shown and described.

707,263. GOLF-BALL. ADDISON T. SAUNDERS, Akron, Ohio, assignor of one-half to Frank A. Seiberling, Akron, Ohio. Filed Sept. 11, 1900. Serial No. 29,734. (No model.)

Claim.—1. A golf-ball comprising an air-tight shell having a central cavity adapted to contain a body of fluid under pressure to form an elastic core, said shell being of such material and thickness and having such rigidity as to maintain its sphericity under light impact, such as the blows used in putting, but being depressible under the impact of heavier blows, substantially as described.

2. A golf-ball comprising an air-tight shell of such material and thickness and having such rigidity as to maintain its sphericity under light impact and having a central cavity adapted to contain a compressed fluid and provided with self-sealing means to retain the compressed fluid therein, substantially as described.

3. A golf-ball comprising an outer shell of such material and thickness and having such rigidity as to maintain its sphericity under light impact and having a central cavity to contain a compressed fluid and a self-sealing fluid-tight lining for said cavity, substantially as described.

4. A golf-ball comprising an inner hollow rubber ball, adapted to be filled with an elastic fluid, a fibrous reinforcing-covering surrounding said ball, and an inclosing shell of gutta-percha, or similar material, substantially as described.

5. A golf-ball comprising an inner hollow rubber ball, adapted to be filled with an elastic fluid, a covering of reinforcing material, as friction-thread wound thereabout, said covering being suitably treated to increase its specific gravity, and an outer shell of gutta-percha, substantially as described.

6. A golf-ball comprising an inner hollow rubber ball, adapted to be filled with an elastic fluid, a covering of reinforcing material, as friction-thread wound thereabout, said covering being suitably treated to increase its specific gravity, and an outer shell of gutta-percha, mixed with strength and weight giving substances, substantially as described.

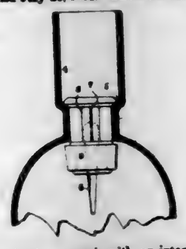
707,264. APPARATUS FOR SETTING OR REMOVING TILES. HERMAN SCHMIDT, Jr., Swanton, Nebr. Filed Oct. 16, 1901. Serial No. 78,823. (No model.)

Claim.—1. In a device for handling tilings or tubes, the combination, of a shaft having upper and lower cross-arms, a cylinder or pipe connected to said arms, spring-catches in the sides of the cylinder or pipe and adapted to project normally therefrom, and jaws projecting from the lower end of the shaft, said jaws having points at their outer ends adapted to enter the joint between two tiles, substantially as shown and described.

2. In a device for handling tilings or tubes, the combination, of a shaft having upper and lower cross-arms, a pipe connected to said arms, said pipe being contracted at its lower end, spring-catches projecting from the sides of the pipe and adapted to support a tile, and spring-actuated jaws projecting at an upward inclination from the lower end of the shaft, substantially as shown and described.

3. In a device for handling tilings or tubes, the combination, of a shaft having cross-arms, a pipe connected to said arms and adjustable vertically thereon, said pipe being contracted at its lower end, spring-catches projecting from the sides of the pipe, jaws hinged to the lower end of the shaft, and springs forcing the jaws outward, said jaws being adapted to be engaged by the lower end of the pipe when the device is used for setting tiles, substantially as herein shown and described.

707,265. NON-REFILLABLE BOTTLE. THOMAS R. SHORTELL, Pittsburg, Pa. Filed July 29, 1901. Serial No. 70,019. (No model.)



Claim.—A bottle having a neck with an integral contracted portion, a shoulder at each end of said contracted portion, the lower shoulder having grooves or passages, a stopper having a neck adapted to fit the neck of the bottle and the grooves adapted to register with the grooves in said lower shoulder, a flange at the upper end of said stopper adapted to fit the upper shoulder of said contracted portion, and a head on the lower end of the stopper adapted to expand under said lower shoulder to prevent the withdrawal of the stopper.

707,266. WAVE-DETECTING DEVICE. HARRY BROOKSHIRE and GREENLEAF W. PICKARD, Philadelphia, Pa., assignors to American Wireless Telephone and Telegraph Company, a Corporation of Arizona Territory. Filed June 3, 1902. Serial No. 109,574. (No model.)

Claim.—1. A wave-responsive device comprising carbon terminals bridged by metallic needles.

2. A wave-responsive device comprising carbon terminals bridged by steel needles.

3. A wave-responsive device comprising carbon terminal blocks, recesses in said blocks, and metallic needles bridging said blocks and resting in said recesses.

4. A wave-responsive device comprising carbon terminal blocks, recesses in said blocks, and steel needles bridging said blocks and resting in said recesses.

5. A wave-responsive device comprising carbon terminals, metallic needle bridging said terminals, and an envelop for said blocks and needles.

6. A wave-responsive device comprising carbon and metallic needles, an envelop for said carbon and needles, a chamber communicating with said envelop, and desiccating material in said chamber.

7. A wave-responsive device comprising carbon plates, perforations in said plates, and needles resting in said perforations.

8. A wave-responsive device comprising carbon plates, perforations in said plates, and steel needles resting in said perforations.

9. A wave-responsive device comprising thin carbon disks, perforations in said disks arranged symmetrically about the centers thereof, metallic needles bridging said disks and resting in said perforations.

10. A wave-responsive device comprising thin carbon disks, and metallic needles bridging said disks.

11. A wave-responsive device comprising thin carbon disks and steel needles bridging said disks.

12. A wave-responsive device comprising carbon disks, perforations in said disks, means for securing said disks in definite relation with respect to each other, and metallic needles resting in said perforations and bridging said disks.

13. A wave-responsive device comprising carbon disks, perforations in said disks, means for securing said disks in definite relation with respect to each other, metallic needles resting in said perforations and bridging said disks, and an envelop inclosing said disks and needles.

14. A wave-responsive device comprising metallic disks, perforations in said disks, means for securing said disks in definite relation with respect to each other, metallic needles resting in said perforations and bridging said disks, an envelop inclosing said disks and needles, a chamber communicating with said envelop, and desiccating material in said chamber.

15. A wave-responsive device comprising terminals of carbon, and a metallic member in loose contact with said terminals.

16. A wave-responsive device comprising terminals of carbon, and a metallic member bridging said terminals.

17. A wave-responsive device comprising terminals of carbon, and a metallic member in loose contact with and bridging said terminals.

18. A wave-responsive device comprising terminals of carbon, and a metallic rod in loose contact with said terminals.

19. A wave-responsive device comprising terminals of carbon, and a metallic rod bridging said terminals.

20. A wave-responsive device comprising terminals of carbon, and a steel rod in loose contact with said terminals.

21. A wave-responsive device comprising terminals of carbon, and a steel rod bridging said terminals.

22. A wave-responsive device comprising carbon blocks, and a metallic rod loosely bridging said blocks.

23. A wave-responsive device comprising carbon blocks, and a steel rod loosely bridging said blocks.

24. A wave-responsive device comprising carbon blocks, and a metallic needle loosely bridging said blocks.

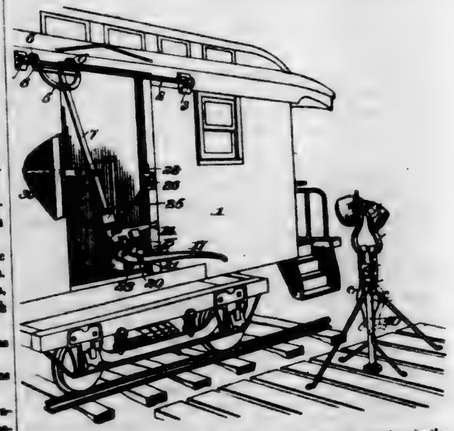
25. A wave-responsive device comprising carbon blocks and a steel needle loosely bridging said blocks.

26. A wave-responsive device comprising carbon blocks, recesses in said blocks, and a metallic needle bridging said blocks and resting in said recesses.

27. A wave-responsive device comprising carbon blocks, recesses in said blocks, and a steel needle bridging said blocks and resting in said recesses.

28. A wave-responsive device comprising carbon blocks, a metallic needle in loose contact with and bridging said blocks, and means for varying the sensitiveness of the contacts.

707,267. MAIL-BAG CATCHER. GEORGE W. SMITH, Rochester, N. Y., assignor to Smith Railway Mail Service Company, Rochester, N. Y., a Corporation of Delaware. Filed May 1, 1901. Serial No. 58,263. (No model.)



Claim.—1. The combination with a car having an opening in the side and a support above the latter and extending longitudinally of the car, of a suspended frame movable on the support and capable of swinging laterally of the car, and a bag-catcher mounted on the frame.

2. The combination with a car having an opening in the side and a support above the latter extending longitudinally of the car, of a suspended

frame movable longitudinally on the support and capable of moving laterally of the car, and a reversible bag-catcher arm mounted on the frame and adapted to be extended in either direction substantially parallel with the side of the car.

3. The combination with a car having an opening in the side and a support above the latter, of a suspended frame movable on the support longitudinally of the car and capable of moving laterally thereof, a reversible bag-catcher on the frame, and a tension member extending between the catcher and the car on the opposite side of the opening from that on which the catcher is located.

4. The combination with a car having an opening in the side and a support extending parallel with the side of the car and removed from the opening, of a suspended frame movable longitudinally of the support and capable of swinging laterally thereon and a bag-catcher on the frame.

5. The combination with a car having an opening in the side, and the support at the upper portion of the opening and extending longitudinally of the car, of a suspended frame movable longitudinally upon the support and capable of swinging laterally thereon, a bag-catcher mounted on the lower end of the frame and means for swinging the catcher toward and from the side of the car.

6. The combination with a car, of a frame pivoted at its upper end on the car and capable of swinging on the pivot laterally of the car, and a mail-bag catcher at the lower end of the frame having the forwardly and downwardly projecting catcher-arm.

7. The combination with a car, of a frame pivoted at its upper end on the car and capable of swinging on the pivot laterally of the car, and a mail-bag catcher at the lower end of the frame having the forwardly and downwardly projecting catcher-arm, and the bag-retaining device at the inner end of said arm.

8. The combination with a car, of a bag-catcher thereon movable bodily laterally of the car and embodying a forwardly-projecting catcher-arm extending downwardly in a plane substantially parallel with the car side.

9. The combination with a car, of a bag-catcher thereon movable bodily laterally of the car and embodying a forwardly-projecting catcher-arm extending downwardly in a plane substantially parallel with the car side and a bag-retaining device at the rear end of said arm.

10. The combination with a car, of a bag-catcher thereon movable bodily laterally of the car and embodying a forwardly and downwardly projecting catcher-arm, and a tension member connected to the catcher and to the car.

11. The combination with a car, and a frame pivoted thereto to swing laterally therefrom, of a mail-bag catcher embodying a forwardly and downwardly extending catcher-arm pivoted at the free end of the frame on a horizontal pivot extending substantially parallel with the side of the car.

12. The combination with a car, and a frame movable laterally therefrom, of a mail-bag catcher pivoted on said frame on a horizontal axis extending in a plane substantially parallel with the side of the car.

13. The combination with a car, and a frame movable laterally therefrom, of a reversible mail-bag-catcher arm pivoted on said frame on a horizontal axis extending in a plane substantially parallel with the side of the car.

14. The combination with a car, and a frame pivoted thereon to swing laterally therefrom, of a mail-bag catcher on the free end of said frame embodying a forwardly and downwardly extending catcher-arm pivoted on an axis extending in a plane substantially parallel with the side of the car.

15. The combination with a car, and a frame pivoted thereon to swing laterally therefrom, of a mail-bag catcher mounted on the free end of the frame, and a toggle having its members pivoted to the car and frame respectively for swinging and holding the frame with the catcher toward and away from the side of the car.

16. The combination with a car, and a frame pivoted thereon to swing laterally therefrom, of a mail-bag catcher mounted on the free end of the frame, and a toggle flexible in one direction only and having its members pivoted to the car and frame for swinging and holding the frame with the catcher away from the side of the car.

17. The combination with a car, a support extending parallel with the side of the car, a suspended frame adjustable longitudinally of the support and capable of swinging laterally, a reversible mail-bag-catcher arm mounted on the free end of the frame and having its inner bag-engaging surface inclined relative to a horizontal plane.

18. The combination with a car, and a frame pivoted thereto at the upper end, of a bag-catcher arm pivoted on the end of said frame on a horizontal axis parallel with the side of the car.

19. The combination with the car, and a frame pivoted thereon, a reversible head mounted on the free end of the frame, and a catcher-arm pivoted on the head on an axis parallel with the pivot of the frame.

20. In a mail-bag catcher, the combination with a support, and a suspended frame pivoted thereon, of a bag-catcher mounted on the free end of the frame and embodying a catcher-arm movable bodily transversely of the support and having its bag-engaging surface inclined relatively to a horizontal plane when in operative position.

21. In a mail-bag catcher, the combination with a support and a frame pivoted thereon, of a bag-catcher mounted on the free end of the frame and embodying a catcher-arm pivoted on an axis parallel with that of the frame and having its bag-engaging surface inclined relatively to a horizontal plane.

22. The combination with a support, and a frame pivoted thereon at its upper end, of a head mounted on the free end of the frame having a laterally-extended arm, and a bag-catcher arm pivoted to the head on a substantially horizontal axis and extending in the same direction as the arm on the head.

23. The combination with the car having the opening, the rod supported above the opening, and the frame movable longitudinally on the rod and capable of swinging thereon, of a reversible bag-catcher arm connected to the free end of the frame, a tension member connected thereto and to the car and means for swinging the catcher outwardly and holding it.

24. The combination with the car having the opening, the support, the frame sliding and swinging thereon, and a catcher-arm on the free end of the frame, of a toggle-arm detachably connected to the frame and to opposite sides of the opening in the car.

25. The combination with the car, having the opening, the frame movable across the opening and swinging toward and from the side of the car and having a bag-catcher at its free end, of a toggle-arm one member of which is detachably connected to the frame, and engaging devices on opposite sides of the door with which the other member of the toggle is adapted to be detachably connected.

26. The combination with a car and a bag-catcher laterally movable therefrom and embodying a catcher-arm extending in the direction of movement of the car and when in operative position having its bag-engaging surface inclined relative to a horizontal plane, of a relatively stationary bag-holder embodying two separated substantially vertically extending bag-supporting arms between which the catching-arm passes when removing the mail-bag therefrom.

27. The combination with a car having a mail-bag catcher thereon embodying the catching-arm extending in a vertical plane, of a bag-holder embodying a support and vertically-extending separated bag-holding arms between which the catcher-arm is adapted to pass, said arms being pivoted to turn on the support on a horizontal axis at right angles to the movement of the car.

28. In a bag-holder, the combination with a support or standard, the frame journaled therein on a horizontal axis and having two vertically-extending and separated supporting-arms on which a bag is held, and means for yieldingly holding the frame with the arms in vertical position.

29. In a bag-holder, the combination with the base or standard, of the frame pivoted thereon on a horizontal axis and embodying the vertically-extending separated arms and the spring-arm arranged between the frame and standard for holding the frame yieldingly with the arms in vertical position.

30. In a bag-holder, the combination with the base or standard, of the frame pivoted thereon on a horizontal axis and embodying the vertically-extending separated arms, the spring-arm mounted on the frame and frictionally engaging the standard to hold the frame yieldingly with the arms extending vertically.

707,268. SMOKING-PIPE. ALBERT S. SPEERS, Chicago, Ill. Filed Nov. 26, 1901. Serial No. 83,782. (No model.)

Claim.—1. A tobacco-pipe having a tobacco-receptacle and a smoke-orifice, and a movable wiper having its stem mounted in said orifice and having an arm arranged within the tobacco-receptacle to traverse the surface of its wall.

2. A tobacco-pipe having a tobacco-receptacle and a smoke-orifice, and a rotary wiper having its stem mounted in said orifice and having an arm arranged within the tobacco-receptacle to traverse its wall.

3. A tobacco-pipe having its bowl provided with a tobacco-receptacle and a smoke-orifice in the bottom thereof, and a rotary wiper having its stem mounted in said orifice and having an arm extending laterally therefrom to traverse the surface of the bottom of the receptacle adjacent to said orifice.

4. A tobacco-pipe having its bowl provided with a tobacco-receptacle and a smoke-orifice in the bottom thereof, a saliva-receptacle in communication with the smoke-orifice, and a stem-opening in the wall of the saliva-receptacle, and a wiper having its stem extending through said saliva-receptacle and smoke-orifice provided with a lateral wiper-arm arranged within the tobacco-receptacle for traversing the bottom of the latter adjacent to the smoke-orifice and provided with a handle located exteriorly of the bowl.

5. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles connected by a smoke-orifice and having a stem-opening communicating with the saliva-receptacle at its side, a filling-plug closing the lower end of the saliva-receptacle, and a wiper carried by said plug extending through said smoke-orifice and having an arm for traversing the inner surface of the bottom of the smoke-receptacle.

6. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles connected by a smoke-orifice and having a stem-opening communicating with the saliva-receptacle at its side, and a movable filling-plug fitted in the bottom of the saliva-receptacle, and a wiper having its stem attached to said plug and extending through the smoke-orifice into the tobacco-receptacle and having an arm for traversing the inner surface of the tobacco-receptacle.

7. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles connected by a smoke-orifice and having a stem-opening in the side of the saliva-receptacle, a cleaning-plug removably fitted in the lower end of the saliva-receptacle, a wiper carried by the plug and extending through the smoke-orifice into the tobacco-receptacle, and a strainer or filter arranged in the saliva-receptacle between the smoke-orifice and the stem-opening.

8. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles connected by a smoke-orifice and having a stem-opening in the side of the saliva-receptacle, a cleaning-plug removably and revolubly fitted in the bottom of the saliva-receptacle, a wiper carried by the plug and having its stem extended through the smoke-orifice into the tobacco-receptacle and provided with a wiper-arm arranged within the tobacco-receptacle to traverse the wall thereof, and a strainer or filter carried by the stem of the wiper.

9. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles connected by a smoke-orifice and having a stem-opening in the side of the saliva-receptacle, a plug fitted in the lower end of the saliva-receptacle, a wiper having its stem attached to the plug and extending through the smoke-orifice into the tobacco-receptacle and carrying a wiper-arm, and a straining or filtering medium carried by said stem and projecting into the smoke-orifice.

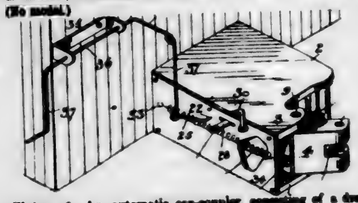
10. A tobacco-pipe having its bowl provided with a tobacco-receptacle, a saliva-receptacle arranged below the tobacco-receptacle and in communication therewith by a smoke-orifice, and a cavity below the saliva-receptacle and communicating therewith by an opening through which the contents of the saliva-receptacle may be removed, the saliva-receptacle having a stem-opening in its wall, a plug removably fitted in the opening in the bottom of the saliva-receptacle, and having a handle or grip projecting beyond the bottom of the saliva-receptacle and arranged wholly in said cavity below the saliva-receptacle, and a wiper carried by the plug and extending through the smoke-orifice into the tobacco-receptacle to clean the same.

11. A tobacco-pipe having its bowl provided with tobacco and saliva receptacles and a communicating smoke-orifice, and having a stem-opening in communication with the saliva-receptacle, and a wiper having its stem extending from the saliva-receptacle through the smoke-orifice and provided at its inner end with a flexible wiper-arm arranged within the tobacco-receptacle and insertible and removable through the smoke-orifice.

12. A tobacco-pipe having tobacco and saliva receptacles connected by a smoke-orifice and provided with a stem-opening in communication with the saliva-receptacle, and a wiper having a stem extending from the saliva-receptacle through the smoke-orifice, provided at its inner end with a lateral flexible wiper-arm arranged within the tobacco-receptacle, and having its stem provided with a straining or filtering medium arranged within the saliva-receptacle.

13. A tobacco-pipe having tobacco and saliva receptacles connected by a smoke-orifice and provided with a stem-opening in communication with the saliva-receptacle, and a wiper having a stem extending from the saliva-receptacle through the smoke-orifice, provided at its inner end with a lateral flexible wiper-arm arranged within the tobacco-receptacle, and having its stem provided with a straining or filtering medium arranged within the saliva-receptacle and projecting into the smoke-orifice.

707,269. AUTOMATIC CAR-COUPLING. JOHN H. STANLEY, Wakenda, Mo., assignor of one-half to George R. Stanley and Joseph G. Watson, Wakenda, Mo. Filed Dec. 31, 1901. Serial No. 87,966. (No model.)



Claim.—1. An automatic car-coupler, consisting of a draw-head, preferably in the shape of a covered box, with the front end open and having a V-shaped recess in its right-hand wall; a perforated lug extending forwardly from the inner face and rear wall of the draw-head; a lock-block hinged to said lug by means of rearwardly-perforated lugs; said lock-block provided in its right and under edge with depressions to receive the locking-arm, and near its left edge with a vertical slot; a bolt passing across said slot; a keeper longitudinally secured to the upper face of said lock-block; a lock-bar provided with a notch and hinged to the upper wall of the draw-head, and adapted to work in said slot and its notch to catch over the bolt crossing said slot; a spring-actuated knuckle hinged in bearings to the front end of the draw-head; a locking-arm secured to the rear face of said knuckle and adapted to pass under said lock-block and into the recesses of the same; a V-shaped extension, extending from the right face of said locking-arm into the V-shaped recess in the right-hand wall of the draw-head; a lever pivoted to the lower face of the top wall of the draw-head and adapted to operate the lock-bar; an elbow-lever pivoted near the center of the draw-head; a U-shaped loop integral with said lever, and extending downwardly and slightly forwardly, and under the said keeper, and adapted to lock said lock-block down, or to raise the same up, substantially as shown and described and for the purposes set forth.

2. An automatic car-coupler, consisting of a draw-head, preferably in the shape of a box with its front end open; a lock-block hinged to the rear wall of said draw-head, and provided in its front end with a vertical slot; a bolt passing across said slot; a keeper longitudinally secured to the upper face of said lock-block; a lock-bar provided with a notch and hinged to the upper wall of the draw-head, and adapted to work in said slot, and catch over said bolt; a spring-actuated knuckle hinged to one side and front end of the draw-head; a locking-arm secured to the rear face of said knuckle, and adapted to pass under said lock-block, and to one side thereof; a lever pivoted to the lower face of the top wall of the draw-head, and adapted to operate the lock-bar; an elbow-lever pivoted near the center of the draw-head; a U-shaped loop integral with said lever, and extending downwardly and slightly forwardly, and under the said keeper, and adapted to lock said lock-block down, or to raise the same up, substantially as shown and described and for the purposes set forth.

3. An automatic car-coupler, consisting of a draw-head, preferably in the shape of a box with its front end open, and having a V-shaped recess in its right-hand wall; a lock-block hinged to the rear wall of said draw-head; the front end of said lock-block adapted to be raised or lowered, and provided near its front end with a vertical slot; a bolt passing across said slot; a keeper longitudinally secured to the upper face of said lock-block; a depending lock-bar provided with a rear notch and hinged to the upper wall of the draw-head, and adapted to work in said slot, and its notch to catch over the bolt across the said slot; a knuckle hinged in bearings to one side and the front end of the draw-head; a locking-arm secured to the rear face of said knuckle, and to pass under said lock-block, and to one side thereof; a V-shaped extension extending from the right face of the locking-arm, and into the V-shaped recess in the right-hand wall of the draw-head; a lever pivoted to the lower face of the top wall of the draw-head, and adapted to operate said lock-bar; an elbow-lever pivoted near the center of the draw-head; a U-shaped loop integral with said lever, and extending downwardly and slightly forwardly under the keeper, and adapted to lock said lock-block down, or to raise the same up; a spring having one end secured to the draw-head, the other to the knuckle, and adapted to swing the knuckle open; walls housing said spring; a double-elbow lever secured to the front end of the couch, and adapted to operate the lever that operates the lock-block, substantially as shown and described and for the purposes set forth.

707,270. PROCESS OF MAKING CAMPHENE. KARL SPIEHAL, Berlin, Germany, assignor to Chemische Fabrik auf Actien, vorm. E. Schering, Berlin, Germany. Filed Jan. 18, 1902. Serial No. 90,264. (No specimens.)

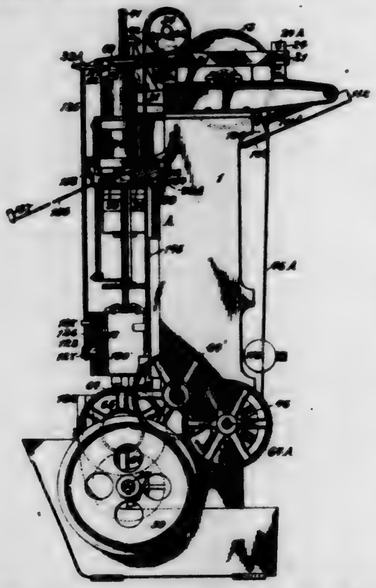
Claim.—1. Process of manufacturing camphene, which consists in heating hydrogen-haloid compounds of pinene with bases of the aliphatic group and isolating by known methods the camphene thus produced, substantially as set forth.

2. Process of manufacturing camphene, which consists in heating hydrogen-haloid compounds of pinene with bases of the aliphatic group, binding the excess of the base with an acid and isolating by known methods the camphene produced, substantially as set forth.

707,271. PROCESS OF MAKING CAMPHENE. KARL SCHAAL, Berlin, Germany, assignor to Gesellschaft Fabrik auf Actien, vorm. E. Schering, Berlin, Germany. Filed Jan. 13, 1902. Serial No. 89,209. (No specimens.)

Claim.—Process of manufacturing camphene, which consists in causing ammonia to react upon hydrogen-haloid compounds of pinene for a long time at a high temperature and isolating in the usual manner the camphene thus produced, substantially as set forth.

707,272. METAL-DRESSING MACHINE. FLAVEL P. SCRIPS, Buffalo, and GUELLE C. SCRIPS, North Tonawanda, N. Y. Filed July 30, 1901. Serial No. 70,316. (No model.)



Claim.—1. The combination with dies constantly rotating in one direction only, and intermittently opening, of a hollow head for the dies, an open tubular spindle vertically located and carrying said head, and a bolt-carrier intermittently rotating in one direction only, longitudinally reciprocating to and from the dies, and adapted to suspend the bolt vertically over said hollow head and spindle.

2. The combination with dies, of a bolt-carrier intermittently rotating in one direction only, for bringing the bolts successively to predetermined positions, a cam and lever for forcing said bolt-carrier to and from the dies, and a driver connected up with the above-named elements for automatically operating the same.

3. The combination of a die-carrying head constantly rotating in one direction only and having a vertical axis, a reciprocating bolt-carrier intermittently rotary around a vertical axis, in one direction only, for bringing successive bolts with their axes vertical centrally over the dies, a device movable with said bolt-carrier for forcing said bolts successively to the rotating dies, and means applied only to the heads of the bolts to prevent them from rotating on their axes.

4. The combination of a die-carrying head constantly rotating in one direction only, and provided with openable jaws which support the dies, a bolt-carrier intermittently rotary in one direction only, for bringing one bolt at a time centrally over the dies, means for forcing said bolt-carrier toward the dies, and an adjustable device governed by said means for opening said jaws at predetermined intervals, and devices connected up with said bolt-carrier for respectively and intermittently preventing the same from turning, said device consisting of a pin, and a slotted lever adapted to catch said pin.

5. The combination with constantly-rotating and intermittently-opening dies, of a slide, a bolt-carrier supported by said slide and intermittently rotary in one direction only, for bringing the bolts to predetermined positions, the axes of the above elements being vertical, means for reciprocating said slide relatively to the dies, a driver connected up with the above-named elements for automatically driving the same, and a cross-head supporting said dies, and movable to and from said carrier.

6. The combination with dies constantly rotating in one direction, of a reciprocating slide for supporting a bolt, an adjustable connecting operating element between said slide and said dies for opening the latter, and a driver connected up with the above-named elements for automatically operating the same, racks on the frame of the machine, a cross-head supporting said dies, and pinions on the cross-head gearing into said racks for varying the distance between said carrier and said dies, and a second driver connected up with all the above-named elements.

7. The combination with dies, of a bolt-carrier rotary around and reciprocating along its axis, a slide supporting said carrier, means for opening and closing said dies, a connecting-rod between said slide and said means, and a yielding cam 14 for starting said slide.

8. The combination with dies, of a head for the same adjustable to different heights, a bolt-carrier, a reciprocating slide supporting said carrier, and an adjustable connection between said dies and said slide.

9. The combination with rotating dies, of a notched carrier-wheel whose axis is vertical, for receiving bolts to hang vertical, and rotary around and reciprocating along its axis to and from said dies whose axis of rotation is vertical, a spindle to which said wheel is attached, a reciprocating slide forming a bearing for said spindle at one side of the center of said slide, means for moving said slide to and from said dies, and devices for bringing the centers of the bolts over the center of the dies.

10. The combination with rotating dies, of a bolt-carrier wheel rotary around and reciprocating along a vertical axis to and from said dies whose axis of rotation is vertical, said carrier consisting of a wheel having notches in its periphery equally spaced from one another, and large enough to receive bolts, and so arranged as to shape and position that the heads of the bolts rest by gravity alone upon the carrier around the edges of the notches, and means for pressing the heads of the bolts against the carrier, and a device independent of the carrier for guiding the heads of the bolts in a predetermined manner.

11. The combination with dies, rotating about a vertical axis, of a bolt-carrier, rotating about a vertical axis, means for discharging a bolt from said carrier, and a device simultaneously feeding a bolt with its axis vertical to said carrier, mechanism successively feeding said bolts while hanging with their axes vertical, to and from said dies, and a driver connected up with said elements and automatically driving the same.

12. The combination with dies rotating about a vertical axis, of a bolt-carrier for receiving, holding and discharging bolts consisting of a wheel having a vertical axis and having notches in its periphery equally spaced from one another, a hub on the wheel, a spindle passing through and connected to and detachable from said hub, a bearing for the spindle, and means for reciprocating said bearing to and from said dies, said means pressing upon the head of a bolt when held centrally over said dies.

13. The combination with dies, of a bolt-carrier with its axis vertical and having notches in its periphery equally spaced, a feeding-chute terminating normally at one notch, a discharge-chute beginning near a second notch which is centrally over said dies, and an openable gate between and in addition to the feeding-chute and the carrier.

14. The combination with dies, of a bolt-carrier adapted to receive, hold, transport, and discharge a bolt, a feeding-chute terminating normally at one portion of the carrier, a discharge-chute beginning near that portion of the carrier which is centrally over said dies, means for moving the said first portion of the carrier to the position of the second portion thereof named, and for bringing a new portion to the position of the said first portion and mechanism for reciprocating said carrier relatively to said dies, and a gate for said chute as an additional element to said chute and said carrier.

15. The combination with dies, of a bolt-carrier wheel with the plane of the wheel horizontal and having notches in its periphery equally spaced, and having the head of the bolt above said wheel, and the shank thereof below said wheel, a feeding-chute terminating normally at one notch with the bolts hanging by their head by gravity alone, a discharge-chute beginning near a second notch which is centrally located over said dies, devices for rotating said wheel, and guides jointly acting with the rotating force of said wheel only upon the head of a bolt for steering the same from its notch to said discharge-chute, which is adapted to support the heads only of the bolts with their shanks hanging vertical by gravity alone.

16. The combination with dies, of a bolt-carrier wheel with a vertical axis having notches in its periphery equally spaced, a feeding-chute terminating normally at one notch, a gate between the chute and carrier, means for opening and closing said gate, a declined discharge-chute with the upper portion horizontal beginning near a second notch which is centrally located over said dies, devices for rotating said wheel, and guides in addition to the other elements named for directing and moving the heads of the bolts tangentially away from said wheel and leading them to said discharge-chute, said guides being so arranged that bolts ahead are driven horizontally into the chute by bolts behind them ahead.

17. The combination with dies, of a bolt-carrier wheel with a vertical axis having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch which is centrally over said dies, said notches receiving the shanks of said bolts, the heads of the bolts resting by gravity alone upon the wheel around the notches, with the shanks hanging loosely vertical, stationary curved guides on opposite sides of the heads only, for guiding the heads of the bolts and extending between the two notches, the shanks of the bolts dangling entirely free, and another guide for the heads extending horizontally from the position of said second notch to said discharge-chute which is declined, the second guides being continuous with the first-named guides, and acting only on the heads of the bolts.

18. The combination with dies, of a bolt-carrier wheel for bringing the bolt centrally over the dies, and having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch, a horizontal chute leading from the carrier to said discharge-chute, the notches being only large enough to receive the vertically-hanging shanks of the bolts, the heads resting entirely by gravity on top of the wheel around the notches, means for rotating said wheel for carrying a bolt from the feeding-chute to said horizontal chute leading to the discharge-chute, and a guide-piece just above said wheel and having a groove for the bolt-heads extending between the two notches and shaped concentrically around the center of said wheel, the groove then becoming straight, instant of curved, from the position of said second notch to said discharge-chute, for the purpose of forming a part of said horizontal chute, and a vertically-reciprocating slide supporting said carrier-wheel, and said guide-piece, which is so arranged and shaped that the head of a bolt is maintained at a predetermined angle with respect to the discharge-chute.

19. The combination with dies, of a bolt-carrier wheel having means for holding a bolt, a feeding-chute and a discharge-chute terminating and beginning at different portions of said wheel, a guide for the head of the bolt between the two portions named and extending beyond that portion at which the discharge-chute is located, and having a hole, a slide supporting said wheel, and having a plunger-head passing through said hole and acting upon the head of the bolt, and means for depressing said slide together with the bolt-carrier endwise to said dies.

20. The combination with dies, of a bolt-carrier wheel having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch, which is centrally over said dies, said notches receiving the shanks of bolts, the heads of the bolts resting upon the wheel and around the notches, a stationary curved guide-piece for guiding the head of the bolt and located between the two notches and extending beyond the second notch to said discharge-chute, said guide-piece having a hole centrally over the dies, a slide for supporting said carrier, and a plunger-head attached to said slide and adapted to bear upon the head of a bolt which is located just below said hole.

21. The combination of a rotating wheel having peripheral notches, a feeding-chute declined toward said wheel and normally terminating at one of said notches and adapted to hold bolts with their axes substantially vertical, a gate independent of the carrier and chute for retaining bolts in said chute and located between the latter and said wheel, a device for intermittently stopping said wheel, means for opening said gate, and a constantly-rotating cam for governing the intermittent stopping of said wheel.

22. The combination of a bolt-carrier rotating about a vertical axis, adapted to receive bolts, a feeding-chute normally terminating at said carrier and declined in a straight line, a gate for retaining bolts in said chute and located near the latter and near said carrier, and devices for intermittently stopping said carrier and opening said gate, which alone is adapted to release only one bolt at a time to fall by gravity upon said carrier, and means for adjusting the time of opening of said gate.

23. The combination of a rotating bolt-carrier adapted to receive bolts, a feeding-chute normally terminating at said carrier, a gate for retaining bolts in said chute and located between the latter and said carrier, devices for intermittently stopping said wheel and opening said gate, a single shaft connected up with the above-named elements for automatically operating the same, a second driving-shaft connected up with the first-named shaft, and means for changing the relative speed of the two shafts.

24. The combination of a bolt-carrier wheel having peripheral notches and its axis vertical, a feeding-chute in which are located bolts which are free to slide with their axes vertical by gravity alone entirely from said chute into said notches, a gate acting to stop said bolts, and projecting under said chute to set upon the shanks of said bolts, means for intermittently opening said gate, and devices for intermittently moving said carrier-wheel, the carrier being on a lower level than the delivery end of said feeding-chute, and said gate being so timed to set, that only one bolt is released at each opening and the parts being so proportioned and arranged that the gate in closing enters the space between the shanks of two bolts which are respectively on the carrier and in the chute.

25. The combination of a bolt-carrier wheel having peripheral notches, a feeding-chute in which are located bolts which are free to slide by gravity alone, entirely from said chute into said notches, a gate acting to stop said bolts, means for intermittently opening said gate, devices for intermittently moving said carrier-wheel, and a stop 54ª above said wheel so located and shaped as to maintain the heads of the bolts at predetermined angles relatively to said wheel, and said chute holding the heads at predetermined angles relatively to said stop.

26. The combination of a bolt-carrier wheel having peripheral notches, a feeding-chute in which are located bolts which are free to slide by gravity alone entirely from said chute into said notches, a gate acting to stop said bolts, means for intermittently moving said carrier-wheel, a stop 54ª above said wheel so located and shaped as to maintain the heads of the bolts at predetermined angles relatively to said wheel, and said chute holding the heads at predetermined angles relatively to said stop, guides for said heads having a curved guiding-surface leading from the stop 54ª to near the position of a given discharge-chute, and then continuing as a rectilinear guide 54ª to said discharge-chute.

27. The combination with dies, of a bolt-carrier wheel having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch which is centrally over said dies, said notches receiving the shanks of said bolts, the heads of the bolts resting upon the wheel around the notches, a stationary curved guide for guiding the heads of the bolts and extending between the two notches, another guide for the heads extending from near the position of said second notch to said discharge-chute, the second guides being continuous with the first-named guides, said feeding-chute being adapted to contain bolts which are free to slide by gravity alone, entirely from said chute into said notches, a gate acting to stop said bolts, means for intermittently opening said gate, and devices for intermittently moving said carrier-wheel.

28. The combination with dies, of a bolt-carrier wheel having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch, which is centrally over said dies, said notches receiving the shanks of bolts, the heads of the bolts resting upon the wheel and around the notches, a curved guide stationary relatively to said wheel for guiding the head of the bolt and located between the two notches and extending beyond the second notch to said discharge-chute, said guide-piece having a hole centrally over the dies, a slide for supporting said carrier and said guide, a plunger-head attached to said slide and adapted to bear upon the head of a bolt which is located just below said hole, said feeding-chute being adapted to contain bolts which are free to slide by gravity alone, entirely from said chute successively into said notches, a gate acting to stop said bolts, means for intermittently opening said gate and devices for intermittently rotating said carrier-wheel.

29. The combination with dies, of a bolt-carrier having peripheral notches, said notches receiving the shanks of said bolts, the heads of the bolts resting upon the wheel around the notches, stops 54ª bearing loosely against the opposite sides of the head of a bolt to prevent the same from turning, a plunger pressing upon the top of the head of the bolt, and means for depressing said plunger and said carrier to the dies.

30. The combination with dies, of a bolt-carrier having peripheral notches for receiving the shanks of said bolts, the heads of the bolts resting upon the wheel around the notches, stops 54ª to prevent the bolts from turning and located at the sides of the heads thereof, a plunger pressing upon the top of the heads, a slide supporting said carrier, stops and plunger, and means for depressing said slide toward the dies.

31. The combination with dies, of an intermittently-rotating bolt-carrier having a series of notches adapted to receive the circular shank of a bolt, so that the head thereof rests by gravity alone, on said carrier, at the receiving position thereof, and stops acting on the squared or hexagonal head of the bolt only at the threading position, for resisting the rotating force of the dies, a plunger-head pressing on the bolt only at the threading position, and means for carrying and forcing said plunger with the bolt to the dies.

32. The combination with dies, of a bolt-carrier having a notch adapted to receive the shank of the bolt so that the head thereof rests by gravity

on said carrier, means for resisting the rotating force of the dies upon said bolt, said means consisting of parallel steps 54^b at the sides of the head of said bolt, said steps following the bolt in its descent to said dies.

33. The combination with dies, of a bolt-carrier having a notch adapted to receive the shank of the bolt so that the head thereof rests by gravity on said carrier, and means for resisting the rotating forces of the dies, upon said bolt, a slide supporting said carrier, a barrel in which said slide reciprocates, and a discharge-chute secured to said barrel and having parallel guides which are a continuation of said steps.

34. The combination with dies, of a bolt-carrier wheel having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch, which is centrally over said dies, said notches receiving the shanks of said bolt, the heads of the bolt resting upon the wheel and around the notches, a curved guide-piece for guiding the head of the bolt located between the two notches and extending beyond the second notch to said discharge-chute, said guide-piece having a hole centrally over the dies, a slide for supporting said carrier, a plunger-head attached to said slide and adapted to bear upon the head of a bolt which is located just below said plunger, said feeding-chute being adapted to contain bolts which are free to slide by gravity alone, entirely from said chute successively into said notches, devices for intermittently moving said carrier-wheel, a gate consisting of a hook in front of the front bolt in said chute, a lever of which said hook forms an extension, a pivot for said lever secured upon said chute, a spring attached to said lever so that its free end bears against said chute for holding the gate normally closed, a pin and roller carried by said lever, an inclined plane bearing against said roller, a rod to which said inclined plane is attached, bearings extending from said chute and supporting said rod and permitting longitudinal movements thereof, said inclined plane being adjustable along said rod, and mechanism for reciprocating said rod at predetermined intervals.

35. The combination of a bolt-carrier adapted to receive bolts, a feeding-chute terminating at said carrier, a gate consisting of a hook in front of the front bolt of said chute, a lever of which said hook forms an extension, a pivot for said lever secured upon said chute, a retractile spring attached to said lever, for holding the gate normally closed, a pin and roller carried by said lever, an inclined plane bearing against said roller, a rod to which said inclined plane is attached, bearings for said rod and permitting only longitudinal movements thereof, said inclined plane being adjustable along said rod, and mechanism for reciprocating said rod at predetermined intervals for opening said gate.

36. The combination of a bolt-carrier wheel having peripheral notches, a feeding-chute in which are located bolts which are free to slide by gravity alone, entirely from said chute into said notches, devices for intermittently moving said wheel, a stop 54^b above said wheel so located and shaped as to maintain the heads of the bolts at predetermined angles with respect to said wheel, and said chute holding the heads at predetermined angles relatively to said stop, a gate consisting of a hook in front of the front bolt in said chute, a lever of which said hook forms an extension, a pivot for said lever, a retractile spring attached to said lever for holding said gate normally closed, a pin and roller carried by said lever, an inclined plane bearing against said roller, a rod to which said inclined plane is attached, bearings for said rod, permitting longitudinal movements thereof, said inclined plane being adjustable along said rod, and mechanism for reciprocating said rod at predetermined intervals for opening said gate.

37. The combination of a chute having a longitudinal groove on the under side thereof, adapted to hold the heads of bolts and inclined sufficiently for the bolts to slide down by gravity alone, a gate in front of the front bolt, and bearing against the shank of said bolt, the heads being within said groove, means for opening and closing the gate, a carrier opposite said gate and immediately adjacent thereto and having a notch for receiving the shank of one bolt at a time, a stop 54^b above said carrier against which the head of a bolt strikes, is stopped, and bears, and eccentric guides above said carrier, one of said guides being a continuation of said stop.

38. In a bolt-machine, a bolt-chute, adapted to contain bolts which are free to slide by gravity from the chute, an angle-plate 98 serving as a lever, a gate in front of the bolts and fastened adjustably to said lever, whose pivot-pin is 101 located in the hole 98^c on top of the chute, a pin and roller carried by said lever, a retractile spring fastened to said lever for holding said gate closed, a rod movable longitudinally, an inclined plane carried by said rod and bearing against said roller, a slide on said rod and guides for said slide, a lug 108 on the slide and a constantly-rotating tripping-finger 20 in whose path said lug is located.

39. In a bolt-machine, a bolt-chute, adapted to contain bolts which are free to slide by gravity from the chute, an angle-plate 98 serving as a lever, a gate in front of the bolts and fastened adjustably to said lever, whose pivot-pin is 101 located in the hole 98^c on top of the chute, a pin and roller carried by said lever, a spring fastened to said lever so that its free end presses against said chute for holding said gate closed, a rod movable longitudinally, an inclined plane carried by said rod and bearing against said roller, a slide on said rod and guides for said slide on said chute, a lug 108 on the slide and a constantly-rotating tripping-finger 20 in whose path said lug is located, said slide being adjustably fixed to said rod, a retractile spring 111^a surrounding said rod and abutting against said slide, a constantly-rotating shaft for operating said tripping-finger 20 and a driver for turning said shaft.

40. In a bolt-machine, the combination of a bolt-feeding chute having a gate, means for opening said gate, a retractile spring for closing the same, a second retractile spring for returning said means to its normal position, and an intermittently-actuating element for operating said means to open said gate.

41. In a bolt-machine, the combination of a bolt-chute, a gate consisting of a pivoted hook provided with a pin and roller, and a reciprocating inclined plane acting on said roller for opening the gate at intervals.

42. In a bolt-machine, the combination of a bolt-chute, a gate consisting of a pivoted hook, a pin said roller provided therefor, a reciprocating rod, and an inclined plane carried by said rod and bearing on said roller.

43. The combination with dies, of a rotary bolt-carrier wheel having notches in its periphery, a feeding-chute terminating normally at one notch, a discharge-chute beginning normally near the next notch, which is centrally over the dies, said notches receiving the shanks of said bolt, the heads of the bolt resting upon the wheel and around the notches, a stationary curved guide-piece for guiding the head of the bolt and located between the two notches and extending beyond the second notch to said discharge-chute, said guide-piece having a hole centrally over the dies, a slide for supporting said carrier, a plunger attached to said slide, passing through said hole, and adapted to bear upon the head of the bolt which is located just below said hole, a pivoted gate for releasing bolts, and standing across the exit of said chute, means for opening said gate, a retractile spring for closing the same, and an intermittently-actuating element for operating said means to open said gate, and consisting of a constantly-rotating tripping-finger, and a lug in the path thereof connected up with said means.

44. In a bolt-machine, the combination of a declined chute in which the bolts have their axes substantially vertical, an openable gate for releasing bolts from said chute, a pivot on top of the chute for said gate to turn upon, a longitudinally-reciprocating rod connected up with said gate, a stop for limiting the motion of said rod, a slide attached to said rod and having bearings supported by said chute, means for returning said rod to its normal position, said chute being located on a higher level than that of said gate, which bears against the shank of the lowest bolt, while the heads of the bolts rest by gravity on the upper surface of said chute.

45. In a bolt-machine, the combination of a chute, an openable gate for releasing bolts from said chute, a longitudinally-reciprocating rod connected up with said gate, a stop for limiting the motion of said rod, a slide attached to said rod and having a bearing, a retractile spring for returning said rod to its normal position, a lug on said slide, and an intermittently-actuating finger in whose path said lug is located.

46. In a bolt-machine, a discharge-chute consisting of inclined tracks 155 and 156, a bracket 153 to which said tracks are bolted, a stationary support for said bracket, a rotating carrier-wheel having notches and having its upper periphery adjacent to and substantially in the same plane with the upper surfaces of said tracks, and parallel guides 54^a on a guide-piece 54 which is above said wheel and movable therewith and whose surfaces are in line with the vertical edges of said tracks, and tracks 54^a serving to guide the bolt-head, by the action of the rotation of said wheel, to a position between said tracks 54^a.

47. The combination of a bolt-feeding chute in which the bolts hang substantially vertical, the one behind the other, and which is inclined, a gate in front of the bolts at the exit of the chute, a notched bolt-carrier for receiving bolts from said chute, devices for turning said carrier to bring the bolt centrally over the dies of the bolt-machine, means for holding the bolt from turning on its axis when over said dies, a plunger bearing upon the head of said bolt, a reciprocating slide supporting said plunger and said carrier, mechanism controlled by said slide for opening said dies, a discharge-chute, guides for directing said bolt from the carrier to said discharge-chute, and a single driver connected up with all of the above-named elements for automatically operating the same.

48. The combination with constantly-rotating and intermittingly-opening dies, of a slide 38, a bolt-carrier, supported thereby, a ratchet-wheel for said carrier, a pawl adapted to engage with said wheel, a slide 21 supporting said pawl, a cam 13, a lever connected with the slide 38 and having a pin and roller engaging with said cam, and a second cam 19, engaging with the slide 21.

49. The combination with constantly-rotating and intermittingly-opening dies, of a slide 38, a bolt-carrier, a spindle therefor, a ratchet-wheel supported on said spindle, a pawl adapted to engage with said wheel, a slide 21 supporting said pawl, cams connected up respectively with said slides, and a constantly-rotating shaft for said cams.

50. The combination with constantly-rotating and intermittingly-opening dies, of a slide 38, a bolt-carrier, a spindle therefor, a ratchet-wheel supported on said spindle, a pawl adapted to engage with said wheel, a slide 21 supporting said pawl, cams connected up respectively with said slides, a constantly-rotating shaft for said cams, and a catch governed by the motions of the slide 21 and 38 for intermittently locking said ratchet-wheel.

51. The combination of a bolt-carrier wheel having notches, a reciprocating slide, a spindle supporting said wheel and extending through the whole length thereof and projecting above the top thereof, a ratchet-wheel fixed on the upper end of said spindle and having as many teeth, consisting of pins on the top thereof, as there are notches in said bolt-carrier, said teeth projecting downward to form projections on the under side of said wheel, and adapted to be locked by a pivoted catch, which consists of a lever having a hole for receiving one of said pins, a spring constantly pressing said catch upward for locking said pin, a horizontally-reciprocating pawl extending at certain phases into the path of said catch, said pawl being adapted in its forward position to engage with one of said pins on said ratchet-wheel, a constantly-rotating shaft, a cam thereon, a slide 21 supporting said pawl, and a pin and roller supported on said slide and bearing on said cam.

52. The combination with constantly-rotating and intermittently-opening dies, of a slide 38, a bolt-carrier, a ratchet-wheel for said carrier, a pawl adapted to engage with said wheel, a slide 21 supporting said pawl, cams connected up respectively with said slides, a constantly-rotating shaft for said cams, a catch for said wheel governed by the motions of said slide for intermittently locking said wheel, an inclined bolt-feeding chute for supplying said carrier with bolts, and located on a higher level than said carrier, and directly opposite a notch provided in said carrier at its normal position, a gate for releasing said bolt and consisting solely of a hook standing across the exit of said chute for feeding said bolts from said chute to said carrier, a lever supporting said gate and having a pivot-pin, a pin and roller carried by said lever, a spring fastened to said lever to act as a retractile spring therefor for holding said gate closed, a rod movable longitudinally, an inclined plane carried by said rod and bearing against the roller upon said lever, a slide 107 for said rod, guides for said slide 107, a constantly-rotating tripping-finger on one of the above-named cams, and a lug on the slide 107 in the path of said finger.

53. The combination with constantly-rotating and intermittently-opening dies, of a reciprocating slide 38, a bolt-carrier governed longitudinally thereby, a slide 21 governing the rotary motions of said carrier, cams connected up respectively with said slides, a chute for supplying said carrier with bolts, a gate in addition to said slide 38 at the exit of said chute, and means for opening and closing said gate.

54. The combination with constantly-rotating and intermittingly-opening dies, of a reciprocating slide 38, a rotary bolt-carrier governed longitudinally thereby, a slide 21 governing the rotary motions of said carrier, cams connected up respectively with said slide, a chute for supplying said carrier with bolts, a gate for the exit of said chute, means for opening and closing said gate, and connected up with one of said cams, and a common shaft for both of said cams.

55. The combination with constantly-rotating and intermittently-opening dies, of a reciprocating slide 38, a bolt-carrier governed longitudinally thereby, a slide 21 governing the rotary motions of said carrier, cams connected up with said slides respectively, a chute for supplying said carrier with bolts, a gate for the exit of said chute, means for opening and closing said gate, and connected up with one of said cams, a common shaft for both of said cams, a connecting-rod between said dies and the slide 38, a shaft for rotating said dies, and intermediate driving mechanism between the said two shafts.

56. In a bolt-machine, the combination of a bolt-carrier, a slide having a bearing, a spindle for the carrier extending through said bearing, a ratchet-wheel consisting of a disk made rigid with said spindle, pins passing through the disk at equal intervals circularly, and projecting out, both from the upper surface and from the lower surface, the upper portions forming teeth 81, and the lower portions forming stumps 81^a which are adapted to be held and released by a catch, a pawl 99 in whose path the teeth 81 are located successively as often as the bolt rises out of the dies to its highest point, a pivoted lever or catch having a hole in the path of the stumps 81^a, and pivoted to said slide, a spring continually pressing said catch upward toward said stump, an upwardly-formed hook 82^c in the path of said pawl, means for reciprocating said pawl, and a device for re-ciprocating said slide.

57. In a bolt-machine, a rotary bolt-carrier having a ratchet-wheel, a slide carrying a pawl for intermittently rotating said wheel, a pin and roller on said slide, guides consisting of slotted brackets, having notches 23^a, covered by holding-plates 24, a cam with which said roller engages and consisting of a disk having tracks spaced to the diameter of said roller and having the first portion of its curvature an arc equal to about ninety degrees for maintaining said pawl directly over that tooth which is to be caught by it, a second portion of the curvature of said tracks for moving the slide back so as to turn said ratchet-wheel, the next curvature in order being an arc and serving to maintain said pawl in a free position away from said ratchet-wheel, and the fourth portion of the curve being a spiral gradually approaching said center, for moving the pawl again directly over said ratchet-wheel, and means for constantly rotating said cam.

58. In a bolt-machine, the combination of a bolt-carrier, a reciprocating slide supporting said carrier, a lever pivoted to the frame of said machine and pivotally connected to said slide, a constantly-rotating wheel, cams supported thereby and engaging with said lever alternately, for reciprocating the same, and a third cam rotating with the first-named cams, and a pawl and ratchet-wheel connected up with said carrier and with said third cam.

59. In a bolt-machine, the combination of a bolt-carrier, a reciprocating slide supporting said carrier, a lever pivoted to the frame of said machine and pivotally to said slide, a constantly-rotating wheel, cams supported thereby and engaging with said lever alternately, for reciprocating the same.

60. In a bolt-machine, a bolt-carrier, a yielding cam connected up with said carrier, a stop positively limiting the motion of the cam in one direction, a spring for limiting the motion in the other direction in a cushion-like manner, and a pivot-support for said cam.

61. In a bolt-machine, a reciprocating bolt-carrier, a yielding cam connected up with said carrier, for depressing the same, a stop positively limiting the motion of the cam in one direction, a spring for limiting the motion in the other direction in a cushion-like manner, a shaft and wheel carrying said cam, a second cam on said shaft adapted to engage by intermediate devices with said carrier, and a pivot-support for said cam.

62. In a bolt-machine, a bolt-carrier, a reciprocating slide supporting the same, a counterweight for the slide which has a central opening, tracks 80, a sliding block 77 on said tracks and movable back and forth and movable up and down with said slide, a lever pivotally connected to said block, and fulcrumed at the other end to the frame of the machine, a pin and roller on said lever, a cam 14 upon which said roller is adapted to bear, a pivot 14^a, a spring holding said cam away from the center of its rotation, a stop limiting the action of said spring, a wheel carrying said spring and said cam, means for adjusting said spring and consisting of an adjustable lever which supports said spring, said cam being movable toward the center of said wheel, and a cam 15^c carried by said wheel in the path of said roller.

63. In a bolt-machine, a chute consisting of the combination of an inclined beam having a slot on the under side thereof, and having holes 112^a located at intervals, plates 113 serving as tracks for the heads of the bolts and attached to said beam extending toward each other partly beyond the edges of the slot to form a groove in said beam, a spring-guide at one end of the chute, in said slot, opposite said tracks and attached at one end to said beam, and means for adjusting said guide.

64. In a bolt-machine, the combination of a reciprocating element, and means for reciprocating said element, consisting of a wheel, a cam pivoted eccentrically thereon, a spring resisting inward motions of said cam, a stop positively resisting outward movements of said spring, a second cam fixed permanently to said wheel and curving spirally from its periphery part way to the other cam, and means for adjusting the pressure of said spring against the first-mentioned cam.

65. In a bolt-machine, the combination of a reciprocating slide for taking the bolt to and from the dies of the machine, a rotary carrier supported thereon and supporting a ratchet-wheel by which said carrier is rotated, a longitudinally-reciprocating pawl for turning said wheel, and a catch pivoted to said slide, connected up with said wheel for locking the same, and governed, in its movements of locking and unlocking said wheel, by the joint action of said slide and said pawl.

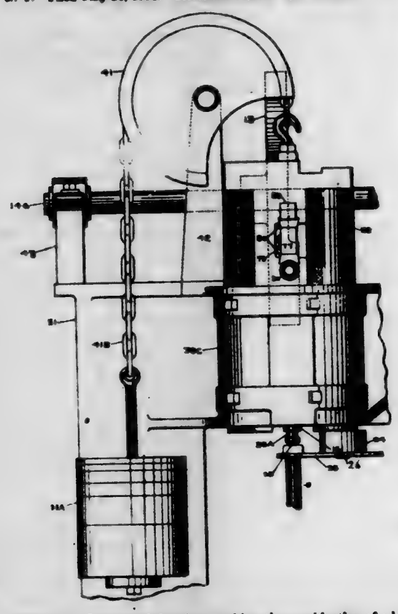
66. In a bolt-machine, the combination of a hollow head for holding the dies and having a hollow spindle, a shaft connected up therewith for rotating the head, a rotary and longitudinally-reciprocating bolt-carrier, a shaft connected up therewith through the medium of cams and levers, for operating the same, means for communicating motion from the first shaft to the second, change-gear and cone-pulleys forming the essential elements of said means.

67. The combination of a rotating head, a bolt-carrier a moving device for manipulating the bolt-carrier with respect to said head and intermediate mechanism between said head and said device for changing the speed of said device relatively to the speed of said head, said mechanism consisting essentially of change-gear wheels, in combination with bolted cone-wheels, and of cams which act jointly upon said carrier, respectively imparting thereto an intermittent rotary motion and a reciprocating longitudinal motion.

68. The combination with dies, of a bolt-carrier wheel for bringing the bolt centrally over the dies, and having notches in its periphery, a

feeding-chute terminating normally at one notch, a discharge-chute terminating normally at the next notch, the notches being only large enough to receive the shanks of the bolts, the heads resting on top of the wheel around the notches, means for rotating said wheel for carrying a bolt from the feeding-chute to the discharge-chute, and a guide-piece just above said wheel and having a groove for the bolt-heads extending between the two notches and shaped concentrically around the center of said wheel, the groove then becoming straight, instead of curved, from the position of said second notch to said discharge-chute.

707,273. **SLIDE FOR METAL-DRESSING MACHINES.** PLATUS P. STIKER, Buffalo, and ORVILLE C. BURTON, North Tonawanda, N. Y. Filed July 30, 1901. Serial No. 70,312. (No model.)



Claim.—1. In a metal-dressing machine, the combination of a barrel having internal circular and radial surfaces, a slide having corresponding circular and radial surfaces and free to reciprocate within said barrel, a plunger-head, projecting centrally from the lower end of said slide, and a carrier supported at one side of the plunger for supporting the object, to be worked upon, centrally under said plunger, the said carrier being supported by the said slide.

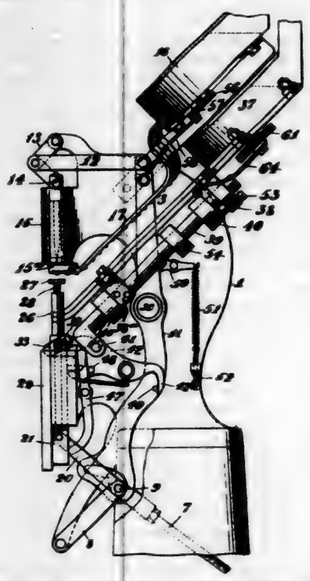
2. In a metal-dressing machine, the combination of a barrel having internal circular and radial bearing-surfaces, a slide having corresponding circular and radial surfaces and free to reciprocate within said barrel, a plunger-head projecting from the lower end of said slide, a counterweight arranged to counterbalance the weight of said slide, and a carrier for supporting said object, and movable with said slide, the said carrier being supported by the said slide.

3. In a metal-dressing machine, the combination of a barrel, gibs therein running longitudinally thereof, and having radial bearing-surfaces, said barrel having circular bearing-surfaces between said gibs, a reciprocating slide within said barrel, and provided with circular and radial bearing-surfaces which bear upon the circular and radial surfaces in said barrel, and a carrier rotary about a spindle located eccentrically to said plunger.

4. In a metal-dressing machine, the combination of a barrel, gibs therein running longitudinally thereof, and having radial bearing-surfaces, said barrel having circular bearing-surfaces between said gibs, a reciprocating slide within said barrel, and provided with circular and radial bearing-surfaces which bear upon the circular and radial surfaces in said barrel, a plunger carried by said slide, a spring for pressing upon said plunger, adjustable stops for limiting the action of said plunger and means for adjusting the pressure of said spring upon said plunger.

5. In a metal-dressing machine, the combination of a plunger supported thereby and consisting of the combination of a rod 55ᵃ threaded at its upper portion and movable up and down in said slide, a threaded rod 141 fixed to said slide, and having a hollow lower portion into which partially extends the rod 55ᵃ, adjustable stop jam-nuts 159 and 160 on said rod 55ᵃ, two other adjustable jam-nuts 150 and 158 on the same rod, a nut 143 on the rod 141, and a spring between said nut and the jam-nuts 150 and 158.

707,274. **MACHINE FOR SETTING BUTTONS.** EDWIN B. STIMPSON, Brooklyn, N. Y. Filed Sept. 30, 1901. Serial No. 76,609. (No model.)



Claim.—1. In a machine for the purpose specified, a work-bed, a perforating and clenching plunger, means for operating the same to perforate the fabric, means for locking the plunger in its advanced, perforating position in order that it may serve as a clenching device, means for feeding buttons to the setting-point at the plunger, means for feeding the eyeleting-eyelets to the other side of the fabric and in alinement with the plunger, a yielding eyelet-spindle alined with the plunger, a tubular anvil embracing said spindle, and means for operating said spindle and anvil for driving the eyelet through the fabric and button, the eyelet being driven and clenched after the locking of the depressed plunger, substantially as set forth.

2. In a machine for the purpose specified, a work-bed, a perforating and clenching plunger, means for operating the same to perforate the fabric, means for locking the plunger in its advanced perforating position in order that it may serve as a clenching device, means for feeding buttons to the setting-point at the plunger, means for feeding the eyeleting-eyelets to the other side of the fabric and in alinement with the plunger, a yielding eyelet-spindle alined with the plunger, a tubular anvil embracing said spindle, means for operating said spindle and anvil for driving the eyelet through the fabric and button, means, operating simultaneously with the plunger, and moving the work-bed to clamp the fabric during the setting operation, and means for positively locking the supports for the work-bed against depression during the setting operation, substantially as set forth.

3. In a machine for the purpose specified, the combination with a work-bed, a pointed piercing and clenching plunger, means for operating the latter to pierce the fabric, means for locking the said plunger in its advanced, perforating position, means for feeding the apertured buttons or the like into alinement with the plunger, and means operating substantially simultaneously with the plunger for moving the work-bed up to clamp the fabric, of means for positively locking the supports of the work-bed when elevated, said means for driving an eyelet up over the plunger and through the fabric and button and clenching the eyelet, substantially as set forth.

4. In a machine for the purpose specified, the combination with the perforating and clenching plunger and its guide, the toggle coupled thereto, the lever 11, the link coupling said lever to the knuckle of the toggle, means for operating said lever to straighten the toggle and form a positive lock for the plunger when it is depressed, means for feeding apertured buttons or the like into alinement with the plunger, a work-bed to support the fabric, and means operating substantially simultaneously with the plunger for moving the work-bed up to clamp the fabric, whereby the said plunger is operated to perforate the fabric and thereafter lock it in its advanced position in order that it may serve as a clenching device, of means for supplying the eyelets and driving them up over the plunger and through the fabric and button, substantially as set forth.

5. In a machine for the purpose specified, the combination with a pointed perforating and clenching plunger and its guide, means for operating the latter to pierce the fabric, means for locking the said plunger in its advanced, perforating position, means for supplying apertured buttons or the like to a position of alinement with the plunger, a work-bed to support the fabric, and means for moving said bed upward substantially simultaneously with the descent of the plunger, means for locking the supports of the elevated bed against depression, of a sliding block 21 and its guide, means for moving said block upward under the work-bed, the tubular anvil 23 in said block, the eyelet-spindle 24, in the hollow of said anvil, its spring 25, and means for feeding the eyelets into the path of said spindle, substantially as set forth.

6. In a machine for the purpose specified, the combination with the plunger 14 and its guide, the toggle 13, coupled to said plunger, the lever 11, having in it the slot 10 with a shoulder 10ᵃ, the link coupling the upper end of said lever with the knuckle of the toggle, the operating-rod 7, coupled to the free end of a rocker 9, the said rocker, and a stud 9 in said rod engaging the slot and shoulder in the lever, of a work-bed, means for supplying buttons into alinement with the plunger over the work-bed, and means for supplying and setting the eyeleting-eyelets, substantially as set forth.

7. In a machine for the purpose specified, the combination with means for supporting and holding the fabric, for piercing the latter, for advancing a clenching-plunger, for locking the said plunger in its advanced position during the clenching operation, and for supplying buttons or the like to be set, of the block 21 and its guide, the rod 7 and link 20 for operating said block, the tubular anvil 23, set in said block, the eyelet-spindle 24 and its spring, said spindle being carried by said block and occupying the bore in the anvil, the eyelet-trunk and bar slidably mounted, and means between the block 21 and said trunk whereby the former, in its upward movement, moves back the trunk, substantially as set forth.

8. A machine for the purpose specified having the following instrumentalities, namely, the fixed guide 22, the block 21 slidably mounted in said guide and having the slots 31, with cam-like branches 31ᵃ, the cam-like supports 26 mounted in said block, the toggle-plates 33, pivotally mounted on said supports through said slots 31 and bearing on the guide 22, said plates being each provided with a stud 34 which engages the slot, the work-bed mounted on said supports 26, and means for moving said block 21 in its guide, substantially as set forth.

9. A machine for the purpose specified having the following instrumentalities, namely, the eyelet-box, a trunk 36 carrying said box, the slide 30 and its guides, the eyelet-trunk being secured to said slide, the rocker 42, connected by a slotted coupling to said slide and having a jaw 43, the sliding block 21 having a stud or projecting part 45 to engage said jaw, and an automatic detent to prevent the return of the slide 30, said detent being actuated for disengagement by the block 21, substantially as set forth.

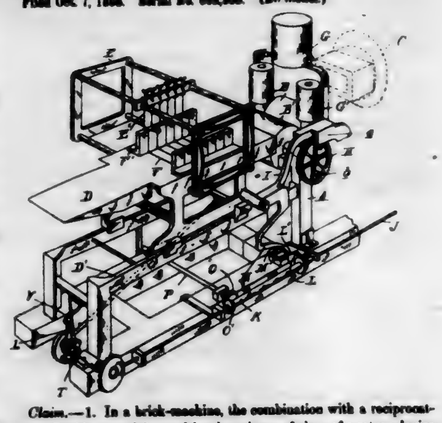
10. A machine for the purpose specified having the following instrumentalities, namely, a plunger and its guide, a toggle for operating said plunger, the lever 11, the link coupling said lever to the toggle, means for operating said lever to straighten the toggle, a rocker 42 having a hook 42ᵃ to engage a stud 49 in the lever and hold the lever against movement, and means for operating the said rocker, substantially as set forth.

11. A machine for the purpose specified having the following cooperating instrumentalities, namely, a plunger and its guide, a toggle for operating said plunger, a main toggle-operating lever, a link coupling one arm of said lever to the knuckle of the toggle, a rocker, means for operating said lever and rocker, and means cooperating with the said lever and rocker whereby the latter locks the former in position after the toggle is straightened for advancing the plunger.

12. A machine for the purpose specified having the following instrumentalities, namely, a fixed guide, a block slidably mounted in said guide, a tubular anvil fixed in said block, means for moving said block, a movable work-bed, and means, actuated by said block during the initial portion of its upward movement, for moving said work-bed a limited distance and for locking it when moved, substantially as set forth.

13. In a machine of the character specified, an inclined box or reservoir to contain buttons or the like to be supplied to the machine, said box having a hopper-like inlet at its upper end, an oscillating brush in a semi-circular compartment at its lower end, a lateral outlet for the buttons from the brush-compartment, and a substantially level apertured partition 59 between the inlet and the brush-compartment, in combination with the trunk which receives buttons from the box, substantially as set forth.

707,275. **BRICK-MACHINE.** WALTER F. STIMPSON, Milan, Mich. Filed Oct. 7, 1898. Serial No. 693,826. (No model.)



Claim.—1. In a brick-machine, the combination with a reciprocating cut-off table moved forward by the column of clay, of a return device therefor comprising a crank, and a lost-motion connection between said crank and table adapted to return the latter in one half-revolution of said crank, and to permit of the free rotation of said crank through the other half-revolution.

2. In a brick-machine, the combination with a reciprocating cut-off table, moved forward by the column of clay, of a return device therefor comprising a two-part telescoping connecting-rod, one part being connected to the table, a crank to which the other part of the rod is connected and means for intermittently actuating the crank for the purpose described.

3. In a brick-machine, the combination with a reciprocating cut-off table moved forward by the column of clay, of a return power mechanism therefor comprising a rod, connecting the table to the power mechanism, one part of the rod being connected to the table and the other part to the actuating device therefor, with a sliding connection between the two parts, and means for intermittently reciprocating the rod connected to the power mechanism, for the purpose described.

4. In a brick-machine, the combination with a reciprocating cut-off table, of a rotating support over which the clay is fed onto said table, a gear-wheel connected with said rotating support, a connecting-bar pivotally attached at one end to said table, and extending over said gear-wheel, the under side of said bar having a rack-face, means for holding said rack, out of engagement with said gear-wheel, during a partial revolution thereof and then allowing the former to drop into engagement with the latter, and means for locking said bar from forward movement while out of engagement with said gear-wheel and for automatically unlocking said bar upon the dropping thereof into engagement.

5. In a brick-machine, the combination with a reciprocating cut-off table, of a rotating support over which the clay is fed onto said table, a gear-wheel connected with said rotating support, a connecting-bar pivotally attached to said table and extending over said gear-wheel, the under side of said bar being provided with a rack-face, means for holding said rack above and out of engagement with the gear-wheel during a partial revolution thereof and then dropping the same into engagement, a flange extending laterally from said bar, and a stop arranged to be in the path of the forward end of said flange while said bar is held in its raised position, the dropping of said bar being adapted to clear said flange from said stop.

6. In a brick-machine, the combination of the roller B, upon which the clay is fed from the clay-mill, and a reciprocating table adapted to be moved forward by the clay through the motion of the roller, of connecting mechanism consisting of the gear-wheel H, having the lug *f* and pin *h*, the connecting-bar I, having the rack-bars *a*, and the flange or cam *e*, cooperating with the pin on the gear-wheel for the purpose described.

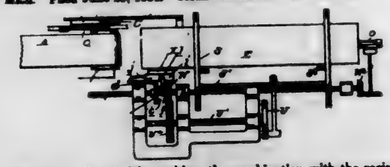
7. The combination with a reciprocating table and its transversely-reciprocating cut-off carriage, of an actuating device therefor, comprising the rack-bar B' and its connecting-gear to the carriage, of a vertically-reciprocating actuating device for the rack-bar and a sliding connection between such difference device and the rack-bar whereby the actuation of the rack-bar takes place during the forward travel of the carriage, substantially as described.

8. In a brick-machine, the combination with the reciprocating table of a transversely-reciprocating cut-off carriage thereon, of an actuating device for the cut-off frame comprising a drive-chain, means for tempera-

rily connecting the drive-shaft with a suitable source of power, the slotted plate Q' adapted to be reciprocated by connection with the drive-shaft, means for holding the slotted plate in a horizontal position and a vertical reciprocating actuating device for the cut-off carriage having sliding engagement with the slotted plate, substantially as described.

9. In a brick-machine, the combination with the transversely-reciprocating cut-off, a reciprocating table upon which the cut-off is carried, of a reciprocating device for the cut-off comprising the vertically-reciprocating rack-bar S' carried by the table, the gear connection from the rack-bar to the cut-off, the slotted head Q', the links R supporting the slotted head continually in a horizontal position, means for intermittently and positively actuating the slotted head and a sliding connection between that head and the rack-bar.

707,276. BRICK-MACHINE. WALTER F. STEPSON, Detroit, Mich. Filed June 25, 1901. Serial No. 65,911. (No model.)



Claim.—1. In a brick-machine, the combination with the reciprocating cutting-table, the cutter mechanism and a rotary driver therefor, of a clutch for automatically coupling said driver to said cutter mechanism, and having a projecting tripping-finger, and a member carried by said table projecting into the path of said tripping-finger to form a stop for disengaging said clutch, said member being cut away at one point to permit of the disengagement of said finger therefrom in the initial movement of said table.

2. In a brick-machine, the combination with the reciprocating cutting-table, the cutter mechanism and a rotary driver therefor, of a clutch for automatically coupling said driver to said cutting mechanism and having a projecting tripping-finger, a member carried by said table projecting into the path of said tripping-finger to form a stop for disengaging said clutch, said member being cut away to permit of the disengagement of said tripping-finger in the initial movement of said table and having a portion for arresting said tripping-finger after the completion of the cut and for maintaining it in its tripped position during the return movement of the table.

3. In a brick-machine, the combination with the reciprocating cutter-table, the cutter mechanism and a rotary driver therefor, of a clutch for automatically coupling said cutter mechanism to said driver, and having a projecting tripping-finger, a member secured to said table comprising two flanges arranged to extend parallel to the plane of movement but in separate planes, one of said flanges forming a stop for said finger in the initial position of said table, and adapted to release the same in the initial forward movement, and the other flange being adapted to rearrest said finger after the completion of the cut, and to guide the same into reengagement with said first flange in the return movement of said table.

4. In a brick-machine, the combination with a cutting-table, and a drive mechanism therefor deriving its movement from the traveling column of clay, of a segmental gear connected with said drive mechanism and a rack-bar connected with said table for engaging with said gear-wheel, said rack-bar having an enlarged forward tooth adapted to first drop into engagement with said gear-wheel.

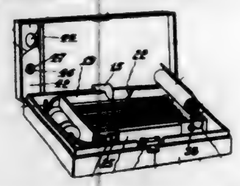
5. In a brick-machine, the combination with a cutting-table and a forward drive mechanism therefor deriving its movement from the traveling column of clay, of a segmental gear-wheel connected with said drive mechanism, a rack-bar connected to said table adapted to drop into mesh with said segmental gear-wheel when brought in registration therewith, a hinged stop-arm adjacent to said rack and a roll upon said arm forming a stop for said rack and adapted when the latter falls in mesh to ride over the upper face thereof until said table is returned.

707,277. COMBINATION MATCH-BOX. CAMILLE ST. JACQUES, Cranbrook, Canada. Filed Jan. 26, 1902. Serial No. 91,174. (No model.)

Claim.—1. A combination match-box comprising an outer box-casing, an inner box attached concentrically therein, and a ball hinged upon one side of the inner box carrying a roll of paper thereon.

2. A combination match-box comprising an outer box and inner box attached concentrically therein, a roll of paper pivotally mounted on one end of said box and fitting in the space between the outer and inner boxes, and a sheath carried by the side of the inner box adapted to receive a pair of tweezers.

3. In a combination match-box, a sheath attached to the under side of the box and having a slot in its upper side, and a knife-blade sliding in said sheath and having a lug projecting through said slot, in combination with a plate-spring pivotally attached to the upper side of the sheath so as to turn in a lateral plane, and adapted to overlie the slot so as to hold the plate in extended or retracted position.



4. A combination match-box comprising an outer box, an inner box concentrically secured therein and adapted to hold matches, and a roll of cleaning material mounted on a bail pivotally attached to one end of the inner box and folding into the intermediate space between the two boxes, and one or more pipe-cleaners folded into the annular space between the two boxes.

5. A combination match-box comprising an outer box, an inner box concentrically secured therein and adapted to hold matches, a roll of cleaning material mounted on a bail pivotally attached to one end of the inner box and folding into the intermediate space between the two boxes, adapted to hold a pair of tweezers, a sheath provided on the outer side of said inner box and a cigar-cutter carried by the cover.

6. A combination match-box comprising an outer box, an inner box concentrically secured therein and adapted to hold matches, a roll of cleaning material mounted on a bail pivotally attached to one end of the inner box and folding into the intermediate space between the two boxes, and a knife-blade sliding in a sheath mounted on the bottom of the box.

7. A combination match-box comprising an outer box, an inner box secured therein and adapted to hold matches, a bail pivotally mounted on said inner box and carrying a roll of paper rotatably mounted thereon, a spring-bar pressing against the lower side of said roll and springs formed on the ends of said bar adapted to press the bar against the roll.

8. A combination match-box comprising an outer box having a cover hinged at the rear side thereof, a spring-plate secured to the bottom of the box and bent outwardly at each side of the box so as to form a spring to hold the cover open at the rear side and a spring-catch at the front side engaging a flanger on the cover to hold it shut, said spring-plate having holes formed therein, in combination with an inner box having a part of its bottom cut away over said spring-plate and tabs 21 on said cut-away portion adapted to hook into the holes 18 and hold the cover to the bottom.

9. In a combination match-box, the combination of a sheath attached to the under side of the box, said sheath having a slot in its upper side and being open at one end, a knife-blade arranged to slide in said sheath and to be projected from said open end and having a lug projecting through said slot, and a plate-spring pivoted to said sheath at one end thereof and adapted to overlie said slot, said plate-spring having its free end formed with a downwardly-turned finger 57 adapted to spring into the said slot and hold the spring in engagement therewith and with a transverse notch at its opposite end adapted to receive and hold said lug when said blade is in projected position.

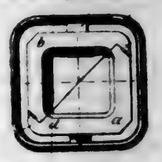
707,278. CAMPHORIC-ACID ESTER OF METHYLENE DIGUAIACOL AND PROCESS OF MAKING SAME. SAMUEL L. SCHEREK, Philadelphia, Pa. Filed May 31, 1902. Serial No. 109,727. (No specimens.)

Claim.—1. The new product described, which is the crystalline camphoric-acid ester of methylene diguaiacol, a stable compound of camphoric acid chemically united with the diguaiacol derivative of methene; crystallizing in white lustrous scales, tasteless, having the empirical formula $C_{29}H_{32}O_6$, melting at about 130° centigrade, insoluble in dilute alkaline solution, and soluble in ether, benzene and hot ethyl alcohol.

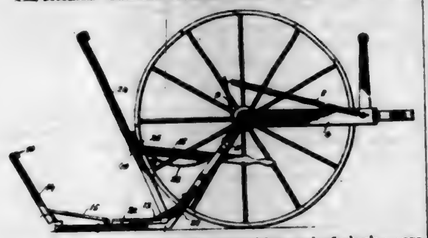
2. The process described, of producing the camphoric-acid ester of methylene diguaiacol, which consists in passing formaldehyde gas through an admixed heated solution of camphoric acid, guaiacol, and phosphorus oxychlorid preliminarily dissolved in a suitable solvent; and then isolating it from the mother-liquor and crystallizing it; substantially as described.

707,279. INGOT-MOLD. JOHN B. DUNN, Syracuse, N. Y. Filed Mar. 20, 1902. Serial No. 100,204. (No model.)

Claim.—An ingot-mold for metal castings, consisting of identical halves finished at the same time in a machine by the same operation, free from all attached means for securing the halves together, each half provided with engaging means fitting the other half for preventing transverse displacement, and interlocking means for preventing longitudinal displacement, each upon the other, substantially as specified.



707,280. CORN-SHOCK LOADER FOR VEHICLES. WILLIAM A. TEA, Bellevue, Ohio; Mary J. Tea administratrix of said William A. Tea, deceased. Filed Nov. 15, 1901. Serial No. 82,262. (No model.)



Claim.—1. A corn-shock loader, comprising a pair of wheels, means for temporarily securing the same to a wagon, a rocking frame pivotally mounted upon said wheels, means for rigidly connecting said frame directly to said wheels so as to be rocked by the rotation thereof, and means for automatically disconnecting said frame from said wheels.

2. A corn-shock loader, comprising carrier-wheels connected by cross-bars, a main frame pivotally connected with said wheels, means for temporarily connecting said frame and said cross-rods rigidly together for the purpose of raising said frame by the rotation of said wheels, a series of folding frames pivotally connected with said main frame and movable relatively thereto, and a hand-lever engaging said main frame and one of said folding frames, for controlling the relative positions of said folding frame.

3. A corn-shock loader, comprising carrier-wheels, a yoke-frame for connecting said carrier-wheels to an exterior movable object, a main frame pivotally connected with said wheels, means for temporarily connecting said main frame and said carrier-wheels rigidly together for the purpose of raising said main frame by the rotation of said wheels, and springs connecting said yoke-frame and said main frame together for compensating the weight of said frame.

4. A corn-shock loader, comprising carrier-wheels, a yoke-shaped frame connected therewith and provided with a roller, a main frame pivotally connected with said wheels and normally movable relatively thereto, means for temporarily connecting said wheels and said main frame rigidly together for the purpose of raising said main frame by the rotation of said wheels, a folding frame flexibly connected with said main frame and free to engage said roller, and flexible connections between said main frame and said folding frame for limiting the play of the said folding frame.

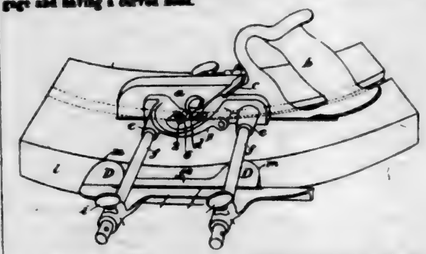
5. A corn-shock loader, comprising carrier-wheels, a yoke-shaped frame provided with a roller, a main frame connected with said wheels and normally movable relatively thereto, means for rigidly connecting said main frame with said wheels for the purpose of raising said main frame, a folding frame pivotally mounted upon said main frame and free to engage said roller, and means for limiting the movement of the said folding frame relatively to said roller.

6. A corn-shock loader, comprising carrier-wheels, a yoke-shaped frame, a main frame pivotally mounted upon said wheels, a locking device for rigidly connecting said main frame and said wheels for the purpose of raising said main frame, and a hand-lever for releasing said locking device, thus enabling the said main frame to be lowered to its original position.

707,281. GROOVING-PLANE. JOSEPH A. TRAFF, New Britain, Conn. Filed Apr. 26, 1902. Serial No. 104,973. (No model.)

Claim.—1. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, and means supported substantially in line with the cutting edge of said bit for engaging a curved surface of the work operated upon, said means consisting of a screw having a curved head.

2. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, and means on the gage substantially in line with the cutting edge of said bit for engaging a curved surface of the work operated upon, said means including a screw working in an opening in the gage and having a curved head.



3. A grooving-plane structure comprising a stock having a bit, means lateral to the stock both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported substantially in line with said cutting edge and having a curved head also engaging the curved surface of the work.

4. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported by the gage substantially in line with the said cutting edge and having a curved head also engaging the curved surface of the work.

5. A grooving-plane structure comprising a stock having a bit, means lateral to the stock both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported in line with said cutting edge and having a curved head also engaging the curved surface of the work, said means each being adjustable toward the other.

6. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported by the gage substantially in line with the cutting edge and having a curved head also engaging the curved surface of the work, said means each being adjustable toward the other.

7. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported by the gage substantially in line with said cutting edge and having a curved head also engaging the curved surface of the work, said gage being adjustable toward and from the stock.

8. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, and a screw supported by the gage substantially in line with said cutting edge and having a curved head also engaging the curved surface of the work, said gage being adjustable toward and from the stock, and said means each being adjustable toward the other.

9. A grooving-plane structure comprising a stock having a bit, means lateral to the stock both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, a screw supported substantially in line with the cutting edge and having a curved head also engaging the curved surface of the work, and scoring devices located beyond the ends and in advance of the said cutting edge.

10. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon, a screw supported by the gage substantially in line with the cutting edge and having a curved head also engaging the curved surface of the work, and scoring devices located beyond the ends and in advance of the said cutting edge.

11. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, a block on the gage both in advance of and to the rear of the cutting edge of said bit and having a curved surface for engaging a curved surface of the work operated upon, and a screw supported by the gage intermediate of said blocks and having a curved head also engaging the curved surface of the work.

12. A grooving-plane structure comprising a stock having a bit, a gage lateral to the stock, a block on the gage both in advance of and to the rear of the cutting edge of said bit and having a curved surface for engaging a curved surface of the work operated upon, and a screw supported by the gage intermediate of said blocks and having a curved head

also engaging the curved surface of the work, said blocks being adjustable toward each other longitudinally of the gage, and said screw being adjustable toward and from the stock.

13. A grooving-plane structure comprising a stock having a bit, a gage parallel with and lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon and adapted to deflect the structure laterally in the planing movements thereof to cause said cutting edge to follow a path parallel with such curved surface, and similar means substantially in line with said cutting edge, said gage being adjustable toward and from the stock, and each of the means specified being adjustable on the gage and consisting of a lateral bearing or block having a curved surface.

14. A grooving-plane structure comprising a stock having a bit, a gage parallel with and lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon and adapted to deflect the structure laterally in the planing movements thereof to cause said cutting edge to follow a path parallel with such curved surface, and a screw supported by the gage substantially in line with said cutting edge and having a curved head also for engaging the curved surface of the work, said gage being adjustable toward and away from the stock, and said means each being adjustable on the gage and consisting of a lateral bearing or block having a curved surface.

15. A grooving-plane structure comprising a stock having a bit, a gage parallel with and lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon and adapted to deflect the structure laterally in the planing movements thereof to cause said cutting edge to follow a path parallel with such curved surface, similar means substantially in line with said cutting edge, and steering devices located beyond the ends and in advance of the cutting edge, said gage being adjustable toward and from the stock, and each of the means specified being adjustable on the gage and consisting of a lateral bearing having a curved surface.

16. A grooving-plane structure comprising a stock having a bit, a gage parallel with and lateral to the stock, means on the gage both in advance of and to the rear of the cutting edge of said bit for engaging a curved surface of the work operated upon and adapted to deflect the structure laterally in the planing movements thereof to cause said cutting edge to follow a path parallel with such curved surface, a screw supported by the gage substantially in line with said cutting edge and having a curved head also for engaging the curved surface of the work, and steering devices located beyond the ends and in advance of the cutting edge, said gage being adjustable toward and from the stock, and said means each being adjustable on the gage and consisting of a lateral bearing or block having a curved surface.

707,282. NEBULIZER. CHARLES TISAX, Chicago, Ill. Filed Mar 28, 1900. Serial No. 10,542. (No model.)

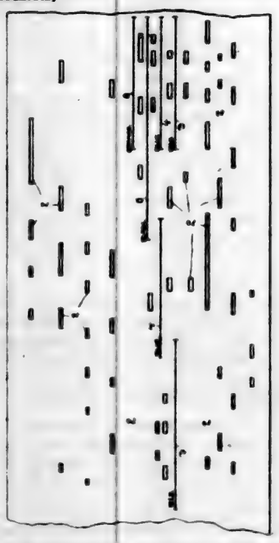
Claim.—1. In a nebulizer, the combination with a standard and air-tube communicating therewith, of a nebula-tube, a plurality of flasks connected with the nebula-tube, a stop-cock between each flask and the nebula-tube, a plurality of connecting-pipes between the air-tube and the flasks, independent stop-cocks in said pipes, and a discharge-nozzle connected with the nebula-tube provided with a cut-off, substantially as described.

2. A nebulizer, comprising a standard and air-tube connected therewith for receiving air under pressure, a nozzle having a cut-off connected to said air-tube, a nebula-tube, a plurality of flasks connected to said nebula-tube, a stop-cock between each flask and the nebula-tube, connecting-pipes between the air-tube and the flasks, a stop-cock for each pipe, and a nozzle connected to the nebula-pipe provided with a cut-off, substantially as described.

3. In a nebulizer, a nebulizing-tube comprising two portions one of which is closed at its end and is provided with a circumferentially-reduced portion above the end and a lateral opening communicating with the interior of the tube, and an enlarged head thereon having a slot, the other portion fitting over the first portion, forming an annular chamber at the reduced portion and also having a lateral opening, substantially as described.

4. In a nebulizer, a nebulizing-tube comprising two portions one of which is closed at its end and is provided with a circumferentially-reduced portion above the end and a lateral opening communicating with the interior of the tube, and an enlarged head with a longitudinal groove, the other portion fitting over the first portion, forming an annular chamber at the reduced portion and also having a lateral opening, one portion being provided with a stud and the other with a notch for holding the parts in adjustment, substantially as described.

707,288. OPERATING-SHEET FOR AUTOMATIC MUSICAL INSTRUMENTS. EDWIN S. VOREE, Summit, N. J., assignor to the Aeolian Company, a Corporation of Connecticut. Filed Oct. 30, 1900. Serial No. 34,917. (No model.)



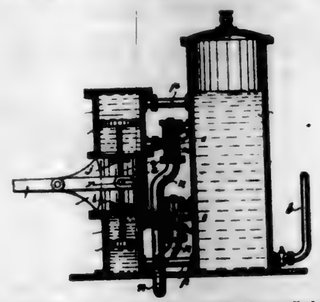
Claim.—1. As a new article of manufacture, an operating-sheet for automatic musical instruments provided with a plurality of sounding-device denoting lines, each of a distinct color, and each of a variably-predetermined length, indicating by its length the period of action of the sounding device it represents.

2. In an automatic musical instrument, the combination with the steps of same, controlling each a register of sounding devices, of an operating-sheet having a plurality of indication-lines, each of a distinct color and each of a variably-predetermined length, each of said lines denoting, by its color, a particular step to be opened for a certain register of sounding devices, and, by its length, the period of action of such step.

3. In an automatic musical instrument, the combination with an operating-sheet, having a plurality of indication-lines, each of a distinct color, and of variably-predetermined lengths, of a plurality of steps on the instrument, colored to correspond with the colored lines on the sheet, the period of action of each step being denoted by the length of its correspondingly-colored line.

707,284. HYDRAULIC PUMP. WILHELM WAGNER, Hamefeld, Germany. Filed Feb. 6, 1901. Serial No. 46,189. (No model.)

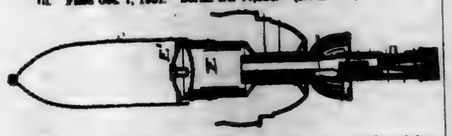
Claim.—1. A hydraulic pump comprising a fluid-column cylinder having a discharge-pipe, the lower pressure-cylinder, the upper pressure-cylinder, the housing whereby the upper pressure-cylinder is supported on the lower pressure-cylinder, the lower and upper pipes whereby the lower and upper pressure-cylinders are connected with the fluid-column cylinder, the valve-casing, connecting the lower pressure-cylinder with the fluid-column cylinder, having suction and pressure valves, a suction-pipe connected with the valve-casing, the pistons working in the lower and upper pressure-cylinders, the rod, connecting the pistons, having a coupling-pin and an operating hand-lever pivoted to the housing and engaging the coupling-pin for reciprocating the pistons, substantially as set forth.



2. A hydraulic pump comprising a fluid-column cylinder having a discharge-pipe, the lower pressure-cylinder, the upper pressure-cylinder of larger diameter than the lower pressure-cylinder, the housing whereby the upper pressure-cylinder is supported on the lower pressure-cylinder, the lower and upper pipes whereby the lower and upper pressure-cylinders are connected with the fluid-column cylinder, the valve-casing connecting the lower pressure-cylinder with the fluid-column cylinder, having suction and pressure valves, a suction-pipe connected with the valve-casing, the differential pistons working in the lower and upper pressure-cylinders, the rod, connecting the pistons, having a coupling-pin and an operating hand-lever pivoted to the housing and engaging the coupling-pin for reciprocating the pistons, substantially as set forth.

3. A hydraulic pump comprising a fluid-column cylinder having a discharge-pipe, the lower pressure-cylinder, the upper pressure-cylinder, the housing whereby the upper pressure-cylinder is supported on the lower pressure-cylinder, the lower and upper pipes whereby the lower and upper pressure-cylinders are connected with the fluid-column cylinder, the valve-casings connecting the lower and upper pressure-cylinders with the fluid-column cylinder, each having suction and pressure valves, suction-pipes connected with the valve-casings, the pistons working in the lower and upper pressure-cylinders, the rod, connecting the pistons, having a coupling-pin and an operating hand-lever pivoted to the housing and engaging the coupling-pin for reciprocating the pistons, substantially as set forth.

707,285. BURNER. MILO S. WALKER, Chicago, Ill., assignor of two-thirds to Max Herskovitz and Abraham I. Herskovitz, Chicago, Ill. Filed Oct. 7, 1901. Serial No. 77,228. (No model.)



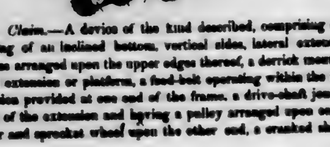
Claim.—1. In a gas-burner of the general class described a mixing-chamber having a small orifice for the admission of a jet of gas under pressure, a tubular passage open at both ends, supported within said chamber in line with said orifice, having a series of perforations in its wall, and means for admitting a supply of air to the mixing-chamber, whereby the jet of gas flows through said tubular passage and carries with it the air so admitted to the mixing-chamber; substantially as described.

2. In a gas-burner of the general class described, a mixing-chamber having a nozzle of small diameter adapted to admit a jet of gas under pressure, a perforated tube open at both ends within said chamber and in line with said nozzle and means for admitting a supply of air to the mixing-chamber, whereby the jet of gas flows through said tube and carries with it the air so admitted to the mixing-chamber; substantially as described.

3. In a gas-burner of the general class described, the combination with the tubular chamber of a Bunsen burner, having an opening in its wall for the admission of air, of a diaphragm below said opening, a perforated tube extending through said diaphragm, a nozzle in line with said tube and in communication with a source of supply of gas under pressure, whereby a jet of gas may be discharged from said nozzle, through said tube and into said chamber, and means for admitting a supply of air to be carried by and with said jet into said chamber; substantially as described.

4. In a gas-burner of the general class described, the combination with the tubular chamber of a Bunsen burner, having an opening in its wall for the admission of air, and provided with a perforated inlet-tube below said openings said tube being of less diameter than the tube of the burner, of a nozzle of small diameter, in line with said tube and opening into a source of supply of gas under pressure, whereby a jet of gas may be discharged from said nozzle through said tube and into said chamber, and means for admitting a supply of air to be carried by and with said jet into said chamber; substantially as described.

707,286. BURNER. MILO S. WALKER, Chicago, Ill., assignor of two-thirds to Max Herskovitz and Abraham I. Herskovitz, Chicago, Ill. Filed Oct. 7, 1901. Serial No. 77,229. (No model.)



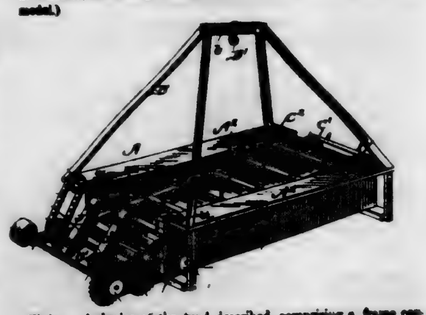
Claim.—1. In a gas-burner, the combination with suitable walls inclosing a mixing chamber, of a gas-nozzle entering said chamber, the lateral walls of said chamber being independently perforated above and below the end of said nozzle and the top wall thereof being perforated in line with said nozzle, and a suitable extension inclosing a chamber beyond the perforation in said top wall; substantially as described.

2. In a gas-burner, the combination with an inlet-nozzle, of an inclosed mixing-chamber which said nozzle enters, provided with a lower series of openings below the end of the nozzle and having means for adjustment and an upper series of openings above the end of the nozzle, a hood arranged about the upper series of openings, a chamber above the mixing-chamber and a diaphragm between the two having a connecting-opening in line with the nozzle; substantially as described.

3. In a gas-burner, the combination with a tubular chamber having two sets of perforations, the upper set of which is inclosed by a suitable hood, of a nozzle opening between said two sets of perforations, a diaphragm in said chamber above the perforations and a reduced tube secured in said diaphragm and in alinement with the nozzle; substantially as described.

4. In a gas-burner, the combination with the tubular casing, A, having perforations, a', a^3, at different points in its length, of a nozzle, b, opening between said perforations, a hood, a^2, inclosing the uppermost of said perforations, a diaphragm, D, extending across the tubular casing, A, and a tubular passage, E, connected to said diaphragm; substantially as described.

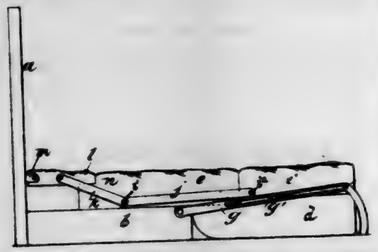
707,287. ATTACHMENT FOR THRESHING-MACHINES. JAMES S. WALKER, Mero, Oreg. Filed Sept. 21, 1901. Serial No. 76,068. (No model.)



Claim.—A device of the kind described, comprising a frame consisting of an inclined bottom, vertical sides, lateral extensions or platforms arranged upon the upper edges thereof, a derrick mounted upon the said extensions or platform, a feed-belt operating within the frame, an extension provided at one end of the frame, a drive-shaft journaled in the end of the extension and having a pulley arranged upon one end, and a gear and sprocket wheel upon the other end, a crushed shaft journaled

in the extension and having a sprocket-wheel at one end and a gear mounted upon the opposite end that meshes the gear of the drive-shaft and a cranked shaft mounted in the frame and having a sprocket-wheel thereon, that connects through a chain belt to the sprocket of the cranked shaft in the said extension, bars connected to the cranked portions of the shafts and having toothed cross-bars connected thereto one of the shafts of the feed-belt having a sprocket that connects to the sprocket of the drive-shaft, substantially as shown and for the purpose specified.

707,288. FOLDING FURNITURE. WILLIAM WEBBER, Weehawken, N. J. Filed Aug. 19, 1899. Renewed May 20, 1902. Serial No. 108,620. (No model.)



Claim.—1. In folding furniture, a base, a slidable seat mounted thereon, a back independent of said seat, and arms or levers pivoted near the top of said back and to the sides of said seat near the rear thereof, whereby, when in extended position, the upper edge of the back impinges against the front edge of said seat, substantially as described.

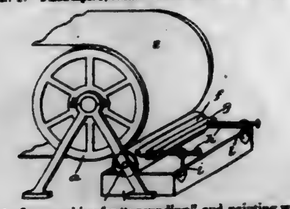
2. In folding furniture, the combination with a base and a folding headpiece, of a slidable seat mounted on said base, a movable back and arms or levers pivoted near the top of said back and to said seat, whereby said back may be moved into the same horizontal plane as, and in front of said seat, substantially as described.

3. In folding furniture, a rigid back, a folding headpiece journaled thereon, and a base; in combination with folding arms, a movable seat mounted on said base and a movable back connected to said seat by arms or levers; arms or levers connecting said seat to said headpiece, and means, actuated by said back for moving said seat, substantially as described.

4. In folding furniture, a rigid back, a movable headpiece journaled thereon and a base; in combination with a movable seat mounted on said base and a movable back; levers connecting said back and seat, and the seat and the headpiece; and means actuated by said movable back for moving the seat and levers, substantially as described.

5. The combination with a rigid back having a movable headpiece journaled thereto, a base and a shaft carrying pinions journaled in said base; of a seat-frame provided with racks engaging said pinions; a movable back, the top thereof being connected with the rear of said seat by levers, and pins projecting from the bottom thereof through slotted levers rigidly connected to the said shaft; and levers pivoted to the seat and to the headpiece, substantially as described.

707,289. WALL-PAPER MACHINE. CHARLES R. WHITON, Brooklyn, N. Y. Filed Apr. 5, 1902. Serial No. 101,606. (No model.)



Claim.—1. In a machine for "grounding" and painting wall-paper, a cylinder around which the paper is passed, a printing-roller supported adjacent thereto and adapted to bear thereon, a paint-roller supported adjacent to the printing-roller and adapted to bear thereon, said paint-roller being supported in a trough or other receptacle, substantially as shown and described.

2. In a machine for "grounding" and painting wall-paper, a cylinder around which the paper is passed, a printing-roller supported adjacent thereto and adapted to bear thereon, a paint-roller supported adjacent to the printing-roller and adapted to bear thereon, said paint-roller being supported in a trough or other receptacle, and being also provided with an adjustable scraper or equalizer which is adapted to bear thereon, substantially as shown and described.

3. In a machine for "grounding" and painting wall-paper, a cylinder around which the paper is passed, a paint-applying roller composed of two longitudinal parts secured together and provided with a covering of textile material, and a scraper and equalizer composed of textile material, and supported adjacent to said roller and adapted to bear thereon and adjustable with reference thereto, substantially as shown and described.

707,290. PACKING-AUGER. ELMER E. LINDSTROM, Halstead, Kans. Filed Jan. 23, 1902. Serial No. 90,989. (No model.)

Claim.—1. In a packing-auger, a gate for closing the space between the flights hinged to the flight above said space and adapted to swing under said flight when the auger is in operation, substantially as set forth.

2. In a packing-auger, an automatically-closing gate for the space between proximal ends of the flights, said gate being hinged to the upper end and adapted to close against the lower end of the said flights, substantially as set forth.

3. In a packing-auger, a gate for closing the space between the proximal ends of the flights, a pintle-rod having connection with the gate, a barrel applied to the stem of the auger, and a spiral spring located in said barrel and having one end connected thereto and its opposite end connected with the pintle-rod, substantially as specified.

4. In a packing-auger, a gate for closing the space between proximal ends of the flights, a barrel applied to the stem of the auger, a spiral spring located within the barrel having its outer end connected thereto, a pintle-rod having the gate connected therewith and having its inner end fitted into the barrel and connected to the inner end of the spiral spring, a packing-washer secured to the inner end portion of the pintle-rod, and a cap coöperating with the said barrel to inclose the said washer, substantially as set forth.

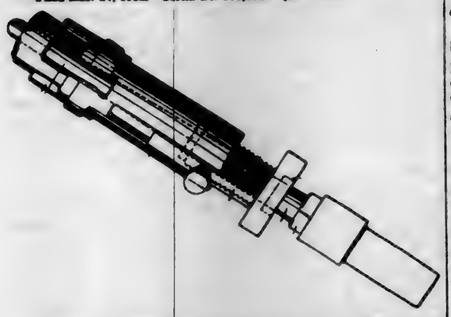
707,291. GAME APPARATUS. STEPHEN A. AKINS, Marvin, Mo. Filed Dec. 13, 1900. Renewed July 7, 1902. Serial No. 114,641. (No model.)

Claim.—1. A game apparatus comprising a runway, a gun at one end of the runway, a plurality of alleys leading laterally from the runway, and a reversible tumbler pivoted above each alley and having a portion depending into the alley for engagement by a body passing through the alley to reverse the tumbler and a common support disposed to receive the tumblers in their reversed positions.

2. A game apparatus comprising a runway, a plurality of alleys leading laterally from the runway, a gun at one end of the runway and adapted to discharge a ball along the runway, the outermost alley being unobstructed, a ball, a striker for the ball pivotally mounted with one end in an alley for engagement by a body discharged from the gun and passing through the alley to operate the striker, and a reversible tumbler for each of the remaining alleys, each of said tumblers having a depending portion lying normally in its respective alley for engagement by a body discharged from the gun, to operate the tumbler.

3. A game apparatus comprising a runway, a plurality of alleys leading laterally from the runway, a gun at one end of the runway to discharge a body through the runway, a ball mounted above a runway, a pivoted clapper or striker having a portion depending into an alley for operation by a body passing through the alley, a pivot-rod disposed transversely of the alleys, a reversible tumbler for each of the remaining alleys mounted upon the pivot-rod and adapted for reversal, a depending portion on each tumbler lying normally in its respective alley for engagement by a body passing through the alley to operate it, and a common rest-bar disposed to receive the tumblers in their reversed positions.

707,292. TUBE-EXPANDER. HENRY M. RAIR, Wadsworth, Nev. Filed Mar. 27, 1902. Serial No. 100,181. (No model.)



Claim.—1. The combination in a flue-expander, of a casing, a tubular series of rods, a mandrel, and means in connection with said casing by which the mandrel may be automatically retracted.

2. The combination in a flue-expander, of a casing, a tubular series of rods, a mandrel, means by which the inward movement of said mandrel may be limited and means by which said mandrel may be retracted automatically.

3. The combination in a flue-expander, of a casing, revolvable rods carried thereby, a spreader, stop means upon the casing by which the inward movement of the spreader is limited and means by which the spreader is retracted automatically on engaging said stop.

4. The combination in a flue-expander, of a casing, rollers carried thereby, a left-threaded sleeve concentric with said casing and a mandrel adapted to be inserted through said sleeve and casing.

5. The combination in a flue-expander, of a casing, rollers thereon, a sleeve provided with left threads and turnable in said casing and eccentric therewith, and a mandrel adapted to be inserted in said sleeve and casing to spread the rollers.

6. The combination in a flue-expander, of a casing, rollers thereon, a sleeve threaded and turnable in said casing, a mandrel, and engaging stop, means upon the mandrel and sleeve whereby the mandrel is retracted as it is turned in opposition to the threads on the sleeve.

7. The combination in a tube-expander, of a casing, rollers thereon, a mandrel, a left-threaded sleeve in said casing and turnable in opposition to the mandrel, and an adjustable gage-plate in relation to said sleeve.

8. The combination in a tube-expander, of a casing, rollers thereon, a mandrel, a sleeve having a left-hand thread and in which said mandrel is slidable, a recess in the head of said sleeve, a projection on the mandrel adapted to engage said recess to turn the sleeve and retract the mandrel, and a gage-plate slidable upon the casing and engaging the sleeve.

707,293. HYDRAULIC DREDGE. LEMUEL W. BATES, Chicago, Ill. Filed July 19, 1900. Serial No. 24,203. (No model.)

Claim.—1. In combination with a pontoon, a discharge-pipe carried thereby; a shore discharge-pipe; a flexible connection intermediate said pipes; a pivotal support for the shore discharge-pipe; and means for raising and lowering said support.

2. In combination with a pontoon, a discharge-pipe carried thereby; a shore discharge-pipe; a flexible connecting-section intermediate said pipes; a pivotal support for said shore discharge-pipe supported from the pontoon; and means for changing the height of said support.

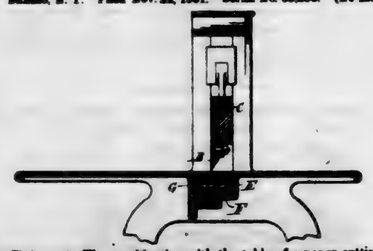
3. In combination with a pontoon; a discharge-pipe carried thereby; a shore discharge-pipe; a flexible connecting-section intermediate said pipes; a pivotal support for said shore discharge-pipe supported from the pontoon; and means for relieving said intermediate section from the thrust of the shore discharge-pipe.

4. In combination with a pontoon, a discharge-pipe carried thereby; a shore discharge-pipe; a flexible connecting-section intermediate said pipes; a pivotal support for said shore-pipe supported from the pontoon; means for adjusting the height of said support; and means for relieving the intermediate flexible section from the thrust of the shore discharge-pipe.

5. In combination with a pontoon, a discharge-pipe carried thereby; arms or levers extending outwardly from said pontoon; a bridge-piece extending across between said arms; a shore discharge-pipe; pivotal connections between said pipe and the bridge-piece; thrust-bars extending from said pivotal connection back to the pontoon; and a flexible section interposed between the discharge-pipe of the pontoon and the shore discharge-pipe.

6. In combination with a pontoon, a discharge-pipe carried thereby; arms or levers C extending outwardly from said pontoon; a bridge-piece extending across between said arms; eyebolts extending down from and adjustably secured to the said bridge-piece; a shore discharge-pipe F; trunnions connected to said pipe and bearing in the eyes of the eyebolts; radius-bars connected to said trunnions and pivotally connected at their opposite ends to the pontoon; and a flexible section H interposed between the discharge-pipe on the pontoon and the shore discharge-pipe.

707,294. PAPER-CUTTING MACHINE. CHARLES D. BLACKHALL, Buffalo, N. Y. Filed Nov. 22, 1901. Serial No. 83,253. (No model.)



Claim.—1. The combination with the table of a paper-cutting machine provided with a groove, of a knife arranged over said groove, a cutting-stick seated in the groove and made narrower than the same, but wider than the distance between the edge of the knife and either wall of the groove, whereby when seated at either side of said groove it will oppose the knife, and a retaining device for holding the cutting-stick against lateral displacement, substantially as set forth.

2. The combination with the table of a paper-cutting machine provided with a groove, of a laterally-adjustable cutting-stick seated in said groove and made narrower than the same, a knife arranged over said groove and located at a shorter distance from both walls of the groove than the width of the cutting-stick, whereby when seated at either side of the groove the cutting-stick will oppose the knife, and a filling strip or strips arranged in the portion of said groove not occupied by the stick, substantially as set forth.

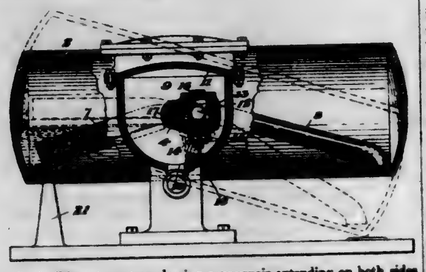
707,295. STEAM-TRAP. JAMES BOHAN, Pittsburg, Pa. Filed Aug. 5, 1901. Serial No. 70,662. (No model.)

Claim.—1. A steam-trap, comprising a steam-tight receptacle, arranged on a fulcrum, an open chamber in said receptacle extending on both sides of the fulcrum, a steam-inlet to said receptacle, and a water-outlet from said receptacle having a valve controlled by the tilting of the receptacle on its fulcrum; substantially as described.

2. A tilting steam-trap, having a steam-tight reservoir extending on both sides of the fulcrum, a steam-inlet leading into one side of said receptacle, a water-outlet from the other side of said receptacle, and a valve in said outlet controlled by movement of the reservoir; substantially as described.

3. A tilting steam-trap having a reservoir on both sides of the fulcrum, and an inner water-pocket on one side of the fulcrum arranged to discharge water to the other side when it reaches a certain level; substantially as described.

4. A tilting steam-trap having a reservoir on both sides of the fulcrum, an inlet-pipe leading to a pocket on one side, an outlet-pipe leading from the other side, and an automatic valve controlling the outlet-pipe: substantially as described.

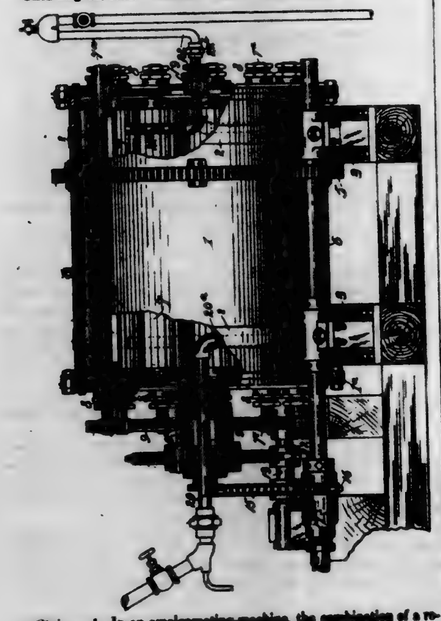


5. A tilting steam-trap, having a reservoir extending on both sides of the fulcrum, the portion of the reservoir above the fulcrum being extended up to a greater distance from the fulcrum than the lower part of the reservoir beneath the fulcrum, to serve as an overbalance-weight, a steam-inlet to said receptacle and a valved water-outlet from said receptacle; substantially as described.

6. A tilting steam-trap, having a steam-tight water-receptacle extending on both sides of its fulcrum, a steam-inlet to said receptacle, a hollow trunnion on one side of said receptacle, a valve-chamber surrounding the trunnion, and an outlet-valve within the chamber, said valve distinct from but operatively connected to said trunnion; substantially as described.

7. A tilting steam-trap, having a steam-tight water-receptacle extending on both sides of its fulcrum, a steam-inlet to said receptacle, a hollow trunnion on one side of said receptacle, a valve-chamber surrounding the trunnion and containing a valve-seat, a valve normally resting by gravity on the seat, and mechanism for lifting the valve, controlled by movement of the receptacle.

707,296. AMALGAMATOR. GEORGE H. BEETHAM, Toledo, Ohio. Filed Aug. 12, 1901. Serial No. 71,714. (No model.)



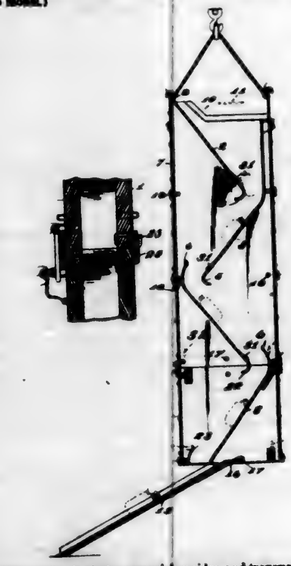
Claim.—1. In an amalgamating-machine, the combination of a rotary cylinder and suitable trunnions therefor, inlet and outlet pipes leading through said trunnions and having bent ends within the cylinder adapted to be turned either upward or downward, a series of agitators within the cylinder, means for hermetically sealing said cylinder, operating means for the cylinder and agitators, separate driving connections between the cylinder and agitators and the operating means, and means for throwing either driving connections out of operation.

2. In an amalgamating-machine, the combination of a rotatable cylinder having an axial inlet and axial outlet, means for hermetically sealing said cylinder, means for placing the contents of the cylinder under hydraulic pressure, agitators disposed within the cylinder, operating means for the cylinder and agitators, separate driving connections between the cylinder and agitators and the operating means, and means for throwing either driving connections into or out of engagement with the operating means whereby both the cylinder and agitators may be axially rotated in unison or the one held stationary while the other is rotated.

3. In an amalgamating-machine, the combination of a cylinder having suitable trunnions, an inlet-pipe leading into the cylinder through one of said trunnions, an outlet-pipe leading from the cylinder through the other of said trunnions, each of said pipes having the ends within the cylinder bent and adapted to be turned upward or downward within the cylinder, the outlet-pipe having an upturned U-shaped bend outside of said cylinder, a series of agitators within said cylinder, operating means for the cylinder and agitators, separate driving connections between the cylinder and agitators and the operating means, and means for throwing either driving connections into or out of engagement with the operating means.

4. In an amalgamating-machine, the combination of a cylinder having an axial inlet and an axial outlet, means for hermetically sealing said cylinder, a series of agitators mounted for rotation within said cylinder, means for rotating said cylinder, a clutch for connecting and disconnecting the cylinder with its operating means, independent mechanism for imparting axial rotation to said agitators, and a clutch for connecting and disconnecting the agitators to their operative mechanism whereby the cylinder and agitators may be given axial rotation or held at rest the one independent of the other.

707,297. CHUTE FOR LOADING WHEAT OR FLOUR ON SHIPS. FRANK W. BELEW, Tacoma, Wash. Filed Mar. 4, 1902. Serial No. 96,708. (No model.)



Claim.—1. A chute, comprising sides and transversely-arranged inclined floors extending between the said sides, one floor leading to another consecutively in opposite directions for directing packages, the upper ends of the floors lapping and curving about the ends of the next floors above, cleats or the like from one floor to another, substantially as described.

2. A chute comprising sides, inclined floors extending between the sides and arranged alternately in different inclined planes, curved end portions on some of the floors lapping the ends of the next floors above for turning packages over and directing them from one floor to the other until they reach the bottom of the chute, substantially as described.

3. A chute comprising a casing formed with a series of inclined floors arranged therein, the said chute being made up of a series of removable sections so that the chute may be made of different lengths, in accordance with the position in which it is to be used, a removable tongue-chute arranged to be pivotally hooked to the lower end of any of the chute-sections so that it may be employed at the bottom of the chute, no matter what its length, for directing packages or sacks from the lower end of the chute to a suitable floor or other support, substantially as described.

4. A chute comprising sides and inclined floors, the said inclined floors having their meeting ends lapped and curved so as to direct packages and parcels from one to the other, means for reinforcing and bracing the sides with respect to each other, and means for raising and lowering or supporting in position the said chute, substantially as described.

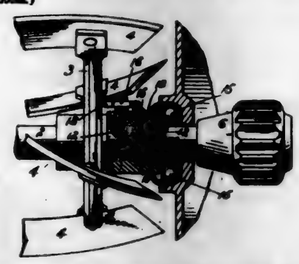
5. A chute made up of a series of sections adapted to fit one upon the other, each of said sections comprising side pieces and inclined floors adjoining the same, one floor leading to another, the floors of the different sections fitting against the ends of the floors of adjoining sections, so as to continuously direct the packages through the chute, and a tongue-chute at the bottom adjustably supported at the bottom of the lowest chute-section, substantially as described.

6. A sectional chute, comprising a main body portion, and one or more sections adapted to be added thereto, each added section having loops at its upper end adapted to engage hooks upon the next section above, and locking means for further supporting the said section, substantially as described.

7. A chute, comprising sections adapted to be joined together, the meeting edges of said sections carrying hooks and loops along one edge while upon the other side of the chute hasps and staples are employed for removably fastening the parts together, substantially as described.

8. A chute, comprising a series of sections fitting one upon the other, inclined package-directing floors within the chutes, means for detachably securing the ends of the sections together so that the floors will register with each other, and eyes arranged at the lower ends of each chute for receiving anchor rods or cables to hold the lower end of the said chute in position, substantially as described.

707,298. BALL-BEARING FOR LAWN-MOWERS. ADELBERT B. CASE, Springfield, Mass. Filed June 20, 1901. Serial No. 65,330. (No model.)



Claim.—1. In lawn-mowers the combination with the ball-bearing adjustable cone thereof, of two cone-adjusting screws therein and means connected with one of said screws whereby both are locked in non-rotatable positions, substantially as described.

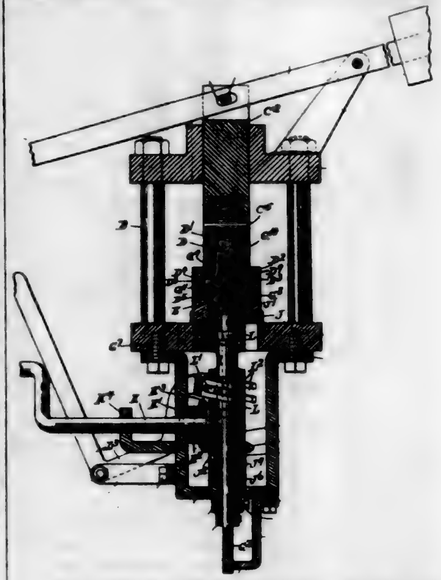
2. In lawn-mowers the combination with the ball-bearing adjustable cone thereof, of two cone-adjusting screws therein, side by side, and a lock-nut on one of said screws whose edge extends over the end of the second one, for screw engagement therewith, whereby said nut becomes locked with both screws, substantially as described.

707,299. MACHINE FOR MOLDING INCANDESCENT-LAMP SOCKETS. CHARLES A. CRASE, Chicago, Ill. Filed Mar. 20, 1902. Serial No. 99,125. (No model.)

Claim.—1. In a machine for molding incandescent-lamp sockets, the combination of a mold-shell with two dies which approach each other within the shell, one of said dies duplex and containing parts one of which reciprocates and rotates while the other reciprocates but does not rotate.

2. In a machine for molding incandescent-lamp sockets, the combination of a mold-shell with two dies which approach each other within the shell, one of said dies duplex and containing parts one of which reciprocates and rotates, while the other reciprocates but does not rotate; the other of said dies adapted to reciprocate but not rotate.

3. In a machine for molding incandescent-lamp sockets, the combination of a mold-shell with two dies which approach each other within the shell, one of said dies duplex and containing parts one of which reciprocates and retains while the other reciprocates but does not rotate, and an additional die-piece which forces the finished product out of the mold.



4. In a machine for molding incandescent-lamp sockets, the combination of a mold-shell with two dies which approach each other within the shell, one of said dies duplex and containing parts one of which reciprocates and rotates while the other reciprocates but does not rotate, and one of which forces the finished product out of the mold, and an opposed die which reciprocates but does not rotate.

5. In a machine for molding incandescent-lamp sockets a die having three parts, concentric with each other, the intermediate part adapted to rotate while it reciprocates, the other parts adapted to reciprocate only.

6. In a machine for molding incandescent-lamp sockets a die having three parts, concentric with each other, the intermediate part adapted to rotate while it reciprocates, the other parts adapted to reciprocate only, and an opposed die-surface which reciprocates only.

7. In a machine for molding incandescent-lamp sockets a mold-shell with dies to form the socket within the mold-shell, and means for withdrawing both of said dies and a die portion adapted to be reciprocated to remove the finished socket from the mold.

8. In a machine for molding incandescent-lamp sockets the combination with the mold and opposed die of a duplex die portion having a cylinder the upper end of which forms the inner screw-threaded surface of the socket, with an interior die portion adapted to be rotated on by the cylinder but to travel with the cylinder and having an upper surface which forms the irregular parts of the socket, the inner portion held from rotation but free to reciprocate, the cylinder provided with means for making it rotate when it is reciprocated.

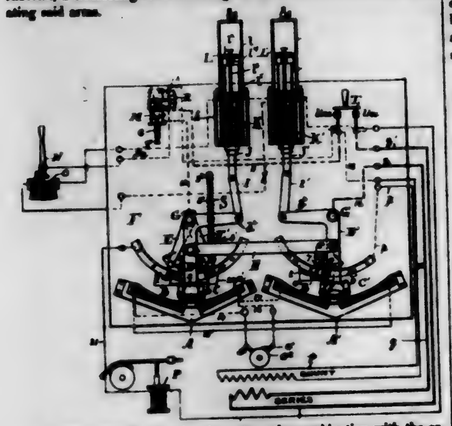
9. In a machine for molding incandescent-lamp sockets the combination with the mold and opposed die of a duplex die portion having a cylinder the upper end of which forms the inner screw-threaded surface of the socket, with an interior die portion adapted to be rotated on by the cylinder but to travel with the cylinder and having an upper surface which forms the irregular parts of the socket, the inner portion held from rotation but free to reciprocate, the cylinder provided with means for making it rotate when it is reciprocated, and an exterior reciprocating cylinder for lifting the finished product from the mold.

707,300. CONTROLLER FOR ELECTRIC MOTORS. WILLIAM H. CRAPHAM, Portland, Me. Filed Mar. 12, 1902. Serial No. 97,988. (No model.)

Claim.—1. In a controller for electric motors, the combination with the armature of a pair of differential rheostats each terminal of each rheostat being connected with one armature-terminal, a rheostat-arm for each rheostat and means for operating said arms in unison with each other.

2. In a controller for electric motors, the combination with the armature of a pair of differential rheostats each terminal of each rheostat

being connected with one armature-terminal, a rheostat-arm for each rheostat, a connecting-rod connecting the two arms and means for operating said arms.



3. In a controller for electric motors, the combination with the armature, of a pair of differential rheostats each terminal of each rheostat being connected with one armature-terminal, a rheostat-arm for each rheostat, a connecting-rod connecting said arms, a pair of solenoids, each adapted to throw said arms in opposite directions.

4. In a controller for electric motors, the combination with the armature, of a pair of differential rheostats each terminal of each rheostat being connected with one armature-terminal, an inverted-L-shaped rheostat-arm for each rheostat, a connecting-rod connecting said arms, a pair of solenoids connecting with the horizontal portion of said arms.

5. In a controller for electric motors, the combination with the armature of a pair of differential rheostats connected with the armature, a pair of connected rheostat-arms for said rheostats, a set of segments adjacent to one of said arms, a contact-finger on said arm adapted to slide on said segments, said segments being connected with the shunt-winding of the motor and said rheostat-arm connecting with the line-terminal.

6. In a controller for electric elevator-motors, the combination with the armature, of a pair of differential rheostats connected with the armature, a pair of connected rheostat-arms for said rheostats, a set of segments adjacent to one of said arms, a contact-finger on said arm adapted to slide on said segments, said segments being connected with the brake-solenoid and thence to one pole of the line and said rheostat-arm being connected with the other pole of the line.

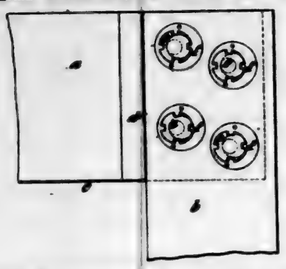
7. In a controller for electric elevator-motors, the combination with the armature, of a pair of differential rheostats connected with the armature, a pair of connected rheostat-arms for said rheostats, a set of segments adjacent to one of said arms, a pair of auxiliary arms adjustably connected with said rheostat-arm, contact-fingers on each of said auxiliary arms adapted to slide on said segments, said segments being connected with the brake-solenoid and thence to one pole of the line and the rheostat-arm being connected with the other pole of the line.

8. In a controller for electric motors, the combination with the armature, of a pair of differential rheostats each terminal of each rheostat being connected with one armature-terminal, a pair of connected rheostat-arms for said rheostats, a pair of solenoids for operating said arms and a spring for holding said arms in their central or normal position.

9. In a controller for electric motors the combination of a pair of differential rheostats connecting with the armature, a pair of connected rheostat-arms for said rheostats, one of said arms being connected with one line-terminal, a pair of solenoids for operating said arms, solenoid-circuits connecting the line-terminals with said solenoids, an emergency-rheostat in said circuit, a solenoid for operating said rheostat in the circuit between said rheostat-arms and the line-terminal, the emergency-rheostat being adapted to throw resistance into the solenoid-circuit when there is an excess of current passing through the main rheostat-arm and means for controlling the solenoid-circuit.

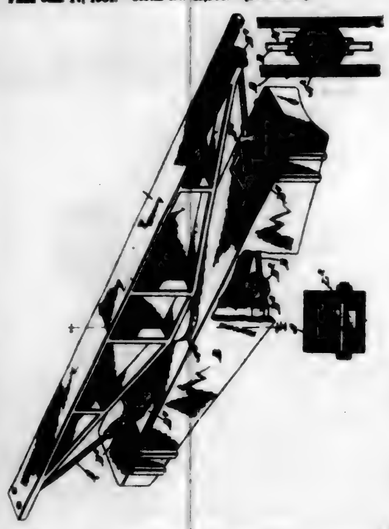
10. In a controller for electric elevator-motors, the combination of a pair of differential rheostats connected with the armature, a pair of connected rheostat-arms for said rheostats, a set of segments adjacent to each of said arms, one set connected to the brake-solenoid and the other connected with the shunt-winding, contact-fingers operated by said arms adapted to slide on said segments, a pair of solenoids for operating said rheostat-arms, circuits for said solenoids connecting with the line-terminals, a spring for bringing said arms to their central or normal position, an emergency-rheostat and an emergency-solenoid operating the same, the resistance in said emergency-rheostat being included in said solenoid-circuits, means for varying the solenoid-circuits, one of said rheostat-arms being connected with one line-terminal through said emergency-solenoid and the rheostat-arm being connected with the other terminal through the series winding of the motor.

707,801. ENGINEER'S SQUARE. WILLIAM CHESTERMAN, Sheffield, England. Filed Nov. 16, 1901. Serial No. 82,549. (No model.)



Claim.—An engineer's square having a stock with a transverse shoulder, a blade having recesses and centered to the stock by screws, and eccentric washers in said recesses beneath the screw-heads arranged to press the blade against the shoulder, substantially as described.

707,802. RAILWAY-CAR. GARDNER W. CHIPLEY, Chicago, Ill. Filed Jan. 17, 1901. Serial No. 43,363. (No model.)



Claim.—1. In a railway-car, the combination of upper and lower bolsters, a center-bearing between the two bolsters adapted to normally sustain the entire weight of a car-body resting upon the upper bolster, and downwardly-converging brace-rods connecting the lower bolster with the upper bolster, said rods being adapted to prevent lateral tilt or rolling motion of the car-body and upper bolster upon said center-bearing.

2. In a railway-car, the combination of a lower bolster having a center-bearing, an upper bolster having its middle portion resting firmly on said center-bearing, and downwardly-converging brace-rods for preventing lateral tilt or rolling motion of the said upper bolster upon the said center-bearing, said brace-rods having their upper ends engaging the outer end portions of the upper bolster, and the lower ends of said rods being arranged to engage the middle portion of the lower bolster.

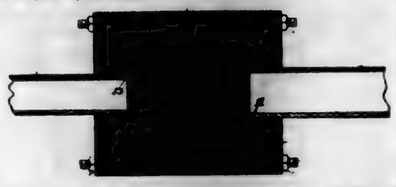
3. In a railway-car, the combination of a lower bolster, provided with a center-bearing, an upper bolster having its middle portion resting firmly upon said center-bearing, a king-pin made integral with said upper bolster and extending downwardly through said center-bearing, and downwardly-converging brace-rods for preventing lateral tilt or rolling motion of the upper bolster upon said center-bearing.

4. In a railway-car, the combination of an upper bolster adapted to support a car-body, a lower truck-bolster, a center-bearing intermediate the two bolsters and located at the longitudinal center of the same, a king-pin extending through said bearing, said bearing sustaining the weight of a car-body resting on said upper bolster, and a pair of downwardly-converging brace-rods arranged to connect the outer end portions of the upper bolster with the center portion of the lower or truck bolster structure, said rods being connected and adapted to sustain either a tensile or endwise compressive strain, according to the direction in which the said car-body tilts or rocks.

5. In a railway-car, the combination of an upper bolster adapted to support a car-body, a lower truck-bolster, a center-bearing intermediate of the two bolsters and located at the longitudinal center of the same, said bearing being adapted to sustain the weight or downward pressure of a car-body resting upon said upper bolster, a king-pin associated with said bearing and serving as a pivotal connection between the two bolsters, and a pair of downwardly-converging brace-rods arranged to connect the outer end portions of the said upper bolster with the central portion of the lower truck-bolster structure, and adjusting devices whereby said rods may be made normally subject to tensile strain.

6. In a railway-car, a car or body bolster, a truck-bolster, brace-rods extended from the center-bearing of said truck-bolster to the outer ends of the car or body bolster, and means of connection between the said ends of the car or body bolster consisting in receiving members on said ends and yielding pressure devices between the ends of the brace-rods and the car or body bolster.

707,803. INSULATING-JOINT FOR PIPES. FINDLEY E. CLELAND and EDWARD B. MURRAY, Des Moines, Iowa, assignors of one-third to Joseph Gass, Des Moines, Iowa. Filed Mar. 10, 1902. Serial No. 97,621. (No model.)



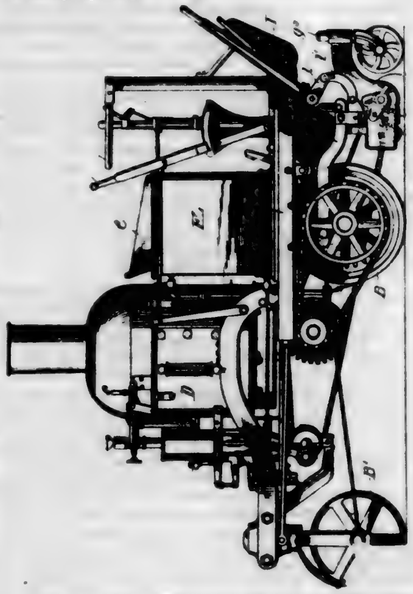
Claim.—1. An improved insulating-joint for pipes, comprising in combination two pipes having flanged adjacent ends, two insulating-blocks having openings in their outer faces to admit the pipes and recesses on the inner faces to receive the flanges, insulating-fillers in said recesses having central openings therein in alinement with the pipes, an insulating packing-sheet having a central opening placed between the blocks, and means for clamping said blocks together.

2. In a device of the class described, the combination of two pipes having flanges at their ends, two insulator-blocks having openings extending through them and recesses surrounding said openings in their inner faces with the flanges resting in said recesses, insulating-fillers in said recesses, said fillers having openings therein, a number of permanent horseshoe-magnets embedded in the inner face of one of said blocks and having the insulating-filler surrounding the end portions and having their ends extending to the opening in the insulating-filler, an insulating-sheet having a central opening placed between the insulating-blocks, bolts passed through the insulating-blocks and the nuts on said bolts, substantially as and for the purposes stated.

707,804. MOTOR LAWN-MOWER. THOMAS COLDWELL and WILLIAM H. COLDWELL, Newburgh, N. Y. Filed Mar. 7, 1902. Serial No. 97,095. (No model.)

Claim.—1. The combination with a motor-carrying frame, provided with traction and lawn-rolling rollers, supporting said frame, of a cutter-frame, located in front of, the said traction and lawn-rolling rollers and provided with cutting mechanism and with ground-engaging devices in constant engagement with the ground when the cutter is in operation for regulating the height of the cut, devices for raising the said cutter-frame for transportation from place to place, and connections between the motor-frame and cutter-frame for transferring substantially the whole weight of the cutter-frame when in operative position to the motor-frame, to add to the effectiveness of the traction-rollers, substantially as described.

2. The combination with a motor-carrying frame provided with traction and lawn-rolling rollers, supporting said frame, of a cutter-frame arranged in front of the said traction and lawn-rolling rollers and provided with cutting mechanism and ground-engaging devices in constant engagement with the ground when the cutter is in operation for regulating the height of cut, devices for enabling the operator to raise said cutter-frame out of operative position at will, and means connected to the motor-frame for supporting substantially the whole weight of the cutter-frame from said motor-frame when the said cutter-frame is in operative position, whereby the ground-engaging devices are prevented from cutting the sod or materially depressing the long grass, substantially as described.



3. The combination with a motor-carrying frame provided with traction and lawn-rolling rollers, supporting said frame, of a cutter-frame arranged in front of the said traction and lawn-rolling rollers, and provided with cutting mechanism and with ground-engaging devices for regulating the height of cut, connections between said frame permitting them to rock transversely with respect to each other, devices enabling the operator to raise the cutter-frame at will, and means connected to the motor-frame for supporting substantially the whole weight of the cutter-frame when the said cutter-frame is in operative position whereby the efficiency of the traction-rollers is increased and the ground-engaging devices of the cutter-frame are prevented from cutting the sod, substantially as described.

4. The combination with a motor-carrying frame provided with traction and lawn-rolling rollers supporting said frame of a cutter-frame arranged in front of said traction and lawn-rolling rollers and provided with cutting mechanism and with ground-engaging devices for regulating the height of cut, connections between said frames permitting them to rock transversely in respect to each other, devices enabling the operator to raise the cutter-frame at will, and means connected to said motor-frame and to said cutter mechanism forward of the line of cut, for transferring substantially the whole weight from the ground-engaging devices to the motor-frame, substantially as and for the purposes set forth.

5. The combination with a motor-carrying frame provided with traction and lawn-rolling rollers entirely supporting said frame, of a cutter-frame located in front of the said traction and lawn-rolling rollers and provided with cutting mechanism and with ground-engaging devices for regulating the height of cut, push-bars connected to the said motor-frame and to said cutter-frame for propelling the cutter-frame, means for enabling the operator to raise said cutter-frame, and springs connected to the motor-frame and supporting substantially the entire weight of the said cutter-frame from the said motor-frame, substantially as described.

6. The combination with a motor-carrying frame provided with traction and lawn-rolling rollers entirely supporting said frame, of a cutter-frame arranged in front of the traction and lawn-rolling rollers, provided with cutting mechanism and with ground-engaging devices forward of the transverse line of cut for regulating the height of cut, push-bars pivoted to said motor-frame and to said cutter-frame, said connections permitting the said frames to rock transversely and longitudinally in respect to each other, means enabling the operator to raise the cutter-frame at will, and springs connecting said push-bars and motor-frame for transfer-

ring substantially the entire weight of the cutter-frame from the ground-engaging devices to the motor-frame, substantially as described.

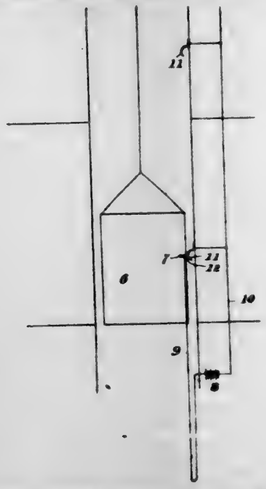
7. In a lawn-mower, the combination with the motor-frame provided with traction and lawn-rolling rollers entirely supporting said frame, of a cutter-frame arranged in front of the said traction and lawn-rolling rollers and provided with ground-engaging devices forward of the transverse line of cut to regulate the height of cut, push-bars connecting the motor-frame and cutter-frame, means for enabling the operator to raise the cutter-frame at will, and springs connecting the motor-frame with the cutter-frame and acting to lift the forward part of the cutter-frame and supporting substantially the entire weight of the cutter-frame, substantially as described.

8. In a motor lawn-mower, the combination with the motor-frame provided with traction and lawn-rolling rollers, entirely supporting said frame, of a cutter-frame arranged in front of said rollers and provided with ground-engaging devices forward of the transverse line of cut to regulate the height of cut, push-bars connecting the said motor-frame and cutter-frame, the connections between said push-bars and the motor and cutter frames permitting said frames to rock transversely and longitudinally with respect to each other, means for enabling the operator to raise the cutter-frame at will and springs connecting the motor-frame with the cutter-frame for supporting substantially the entire weight of the said cutter-frame, substantially as described.

9. In a motor lawn-mower, the combination with the motor-frame provided with traction and lawn-rolling rollers entirely supporting said frame, of a cutter-frame arranged in front of said rollers and provided with cutting mechanism and with ground-engaging devices for regulating the height of cut, connections between said frames for propelling the cutter-frame from the motor-frame, means for enabling the operator to raise the cutter-frame at will, springs connecting the motor-frame with the cutter-frame and arranged to transfer substantially all of the weight from the cutter-frame ground-engaging devices, means for adjusting the tension of said springs, and means for adjusting said ground-engaging devices with respect to the cutter-frame, substantially as described.

10. In a motor lawn-mower, the combination with the motor-frame provided with traction and lawn-rolling rollers entirely supporting said frame, of a cutter-frame arranged in front of said rollers and provided with ground-engaging devices forward of the transverse line of cut to regulate the height of cut and a guard-roller in rear of the line of cut, push-bars pivoted to the motor-frame and provided at their forward ends with pins disposed longitudinally of said bars, said cutter-frame being provided with parts having vertically-elongated apertures to receive said pins, and springs for supporting substantially the entire weight of said cutter-frame, substantially as described.

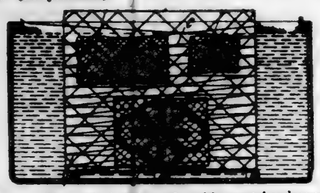
707,805. ELECTRIC SIGNAL FOR ELEVATORS. LEWIS K. CORLETT, Chicago, Ill., assignor of one-half to William D. Allen, Chicago, Ill. Filed Nov. 7, 1901. Serial No. 81,404. (No model.)



Claim.—1. A signal for elevators, comprising an electrically-operated signal carried by the car, and car-actuated contact devices to operate the signal when the floor of the car is flush with a floor of the building.

2. A signal for elevators comprising an electric circuit, an electric signal carried by the car in said circuit, a contact-piece at a floor of the building, and a contact-piece carried by the car in such position as to close the circuit and actuate the signal when the floor of the car is flush with the floor of the building.

707,806. METHOD OF ELECTRODEPOSITING METAL ON LACE. JOHN A. DALY, Washington, D. C. Filed Oct. 15, 1901. Serial No. 78,725. (No specimens.)



Claim.—1. The method of electrodepositing metal on lace and other flexible articles, which consists in preparing the surface of the flexible article to be coated with an electrical conductor, then binding the article to an open-work metallic base by coils of wire having metallic connection to said base, then immersing in a plating-tank for a primary deposit, then removing the wire and base and completing the deposit in usual manner.

2. The method of electroplating metal on lace, which consists in preparing the surface of the lace with an electrical conductor, holding the lace in extended position between wires and making a slight electrodeposit thereon, then removing the wires and completing the deposit in usual manner.

707,807. CARPENTER'S TOOL. MICHAEL F. DOYLE, Scranton, Pa. Filed Mar. 28, 1902. Serial No. 100,128. (No model.)

Claim.—A carpenter's tool, comprising a horizontal ruling-bar having a slot adjacent to one end thereof, said slot extending longitudinally of the bar to a point approximate the center thereof, a guiding-block having an adjustable connection with said bar, the length of adjustment being limited by said slot, and a vertical auxiliary bar extending laterally from said bar at a point adjacent to the non-slotted end thereof, the portion of the horizontal bar beyond the point of connection with the auxiliary bar forming an extension of the horizontal bar and in alinement therewith, whereby a straight edge will be formed along the outer side of said horizontal bar and extension, said extension having a plurality of openings, said block being of a length less than the length of the horizontal bar and movable to a point on either side thereof and free from contact with said auxiliary bar, substantially as and for the purposes set forth.

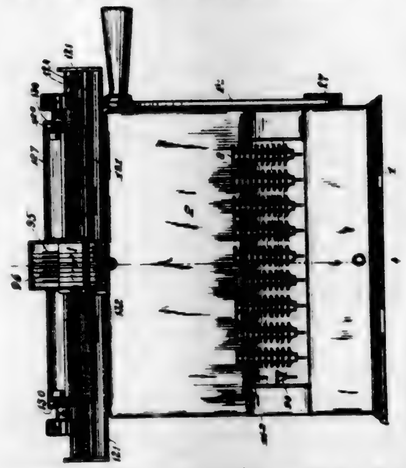
707,808. ENVELOP. CHARLES A. DUNN, West Homestead, Pa. Filed Mar. 21, 1902. Serial No. 99,365. (No model.)

Claim.—1. An envelop-blank consisting of a front and back, the front being of greater length than the back to form wings adapted to fold on said back, and securing-strips formed integral with the front and back and adapted to be doubled so as to engage both the front and back, substantially as described.

2. An envelop comprising a blank having a front forming one side of the envelop and a back forming the other side of said envelop, the front being of greater length than the back and adapted to have its extensions folded over to engage the back, a tongue carried by the front adapted to engage with the back, and end-securing strips carried by the blank, one of said strips adapted to engage the one end of the envelop, and the other strip adapted to engage the opposite end and the edge of the envelop, substantially as described.

3. In an envelop, the combination of an upper and a lower securing-flap, one of said flaps carrying a securing-tongue and the other of said flaps having a cut-away portion adapted to receive said securing-tongue, securing ends carried by said flaps intermediate their ends, said securing ends adapted to be creased and bent upwardly to inclose the sides of the upper and lower securing-flap, one of said securing ends adapted to be bent over the upper sides of the said upper and lower securing-flaps and adapted to inclose said securing-tongue, substantially as described.

707,809. ADDING-MACHINE. HALCOLM ELLIS and NATHAN W PERKINS, Jr., St. Louis, Mo., assignors to Charles H. Filley, St. Louis Mo. Filed Nov. 9, 1901. Serial No. 81,735. (No model.)



Claim.—1. The combination in an adding-machine of a column of keys, a separate pivoted stop-bar connected to be operated by each key, a printing device and an adding device, and a moving part to which the printing and adding devices are connected, the travel of said moving part being limited by the stop-bars when in operation, substantially as described.

2. The combination in an adding-machine of a printing device, an adding device, and a moving part to which the printing and adding devices are each connected, pivoted stop-bars of graded length which in operation limit the travel of the said moving part, substantially as described.

3. The combination in an adding-machine of series of columns of keys, a separate pivoted stop-bar connected to each key, latches for holding said stop-bars in their operative position, means for releasing said latches independently, and means for releasing said latches simultaneously, substantially as described.

4. The combination in an adding-machine of a series of columns of keys, a separate pivoted stop-bar connected to each key, a rack for turning the adding mechanism, and a rack-engaging mechanism operated by the stop-bars, substantially as described.

5. The combination in an adding-machine of two racks connected to the same moving part, an adding device, means for alternately engaging the said racks so that they will rotate the adding device in opposite directions, and pivoted stop-bars of graded length which in operation limit the travel of said moving part, substantially as described.

6. The combination in an adding-machine of type-bearing sectors, pivoted to moving arms, means for raising the type-surface of all sectors that print above the type-surface of the sectors that do not print, and a platen which presses the paper against the raised type, substantially as described.

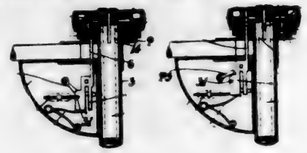
7. The combination in an adding-machine of a total-key, a paper roll about which the paper to be printed passes, and means for automatically rotating the said roll an extra space when the total-key is operated, substantially as described.

8. The combination in an adding-machine of a total-key and a paper-feeding device and means for automatically operating the paper-feed device an extra space whenever the total-key is operated, substantially as described.

9. The combination in an adding-machine of a handle, a rack, and a two-pointed pawl, means for holding said pawl out of engagement with said rack when the handle makes its full stroke in each direction, and means for bringing said pawl into engagement with said rack whenever said handle is reversed before completing its stroke in either direction.

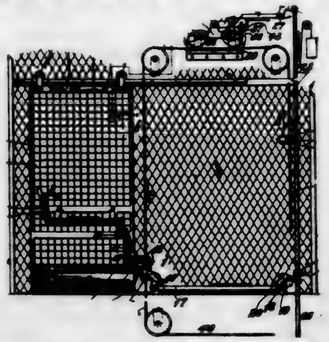
10. The combination in an adding-machine of type-bearing sectors having fixed type thereon numbered "0," "1," "2," "3," and to "9," all the type being normally below the printing-line, an automatic device for raising the type-sector to the printing-line whenever a sector is moved to bring figure "1," or a higher number into printing position, on the sector so moved and all type-sectors to the right, and an inking device which operates to ink the type before the same are brought to the printing-line.

707,810. BICYCLE-LOCK. JOYCE C. FISHER, Mussoorie, India. Filed Apr. 5, 1902. Serial No. 101,577. (No model.)



Claim.—In a bicycle, the combination with the head or socket and the steering-post therein, of a transversely-arranged disk at the upper end of said socket, a second disk carried by the post adjacent to said first-named disk, and a locking-bolt slidingly supported, said bolt passing through an opening in the first disk and engaging a recess in the second disk, substantially as described.

707,811. SAFETY DEVICE FOR ELEVATORS. JOSEPH W. FLEMING, Philadelphia, Pa., assignor of one-half to Hiram Horter, Jr., Philadelphia, Pa. Filed Apr. 30, 1902. Serial No. 105,956. (No model.)



Claim.—1. In an elevator, a door of the elevator-shaft provided with a foot projecting laterally therefrom, a secondary lever adapted to engage said foot, a cable for operating the power mechanism of the elevator, means connected with said lever for clamping and releasing said cable, and a primary lever adapted to operate said secondary lever to remove the latter from the path of said foot.

2. In an elevator, a door of the elevator-shaft, a primary lever mounted thereon, a secondary lever mounted on the elevator-shaft, a foot on the door adapted to be engaged by said secondary lever, means on the door for operating said primary lever and thereby removing the secondary lever from the path of said foot, and means connected with the secondary lever for operating mechanism that engages and releases the starting and stopping cable of the elevator.

3. In an elevator, a bar, mechanism controlling the same operated from the door of the elevator-shaft, a starting and stopping cable, mechanism connected with said bar adapted to engage said cable, a lock on the elevator-shaft adapted to engage said bar, and means on said cable adapted to engage said lock and throw back the same.

4. In an elevator, a starting and stopping cable, means for controlling the same, a lock adapted to engage a member of said means, and a

device on said cable adapted in its motion to engage said lock and throw back the same from said member.

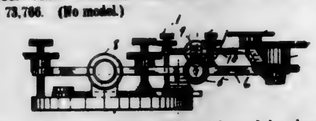
5. In an elevator, a starting and stopping cable, a bed over which the same passes, an eccentric-roller opposite to said bed, a support for said roller, means for lowering and raising said roller, and connections for said means with devices extending from the door of the elevator and the elevator-shaft, whereby the support of said roller is moved in opposite direction.

6. In an elevator, a starting and stopping cable, a locking device therefor, and means for releasing a member of said device from the lock itself consisting of a shoulder on said cable, and a projection on the bolt of said lock, said projection being adapted to be engaged by said shoulder.

7. In an elevator, a bar, a starting and stopping cable, a door provided with means for operating said bar, and a clamping device for said cable adapted to be operated by said bar, in combination with a lock on the elevator-shaft adapted to engage said bar and means on said cable adapted to engage the bolt of said lock.

8. In an elevator, a door of the elevator-shaft, a primary lever mounted thereon, a secondary lever mounted on the elevator-shaft, a foot on said door adapted to be engaged by said secondary lever, said secondary lever being adapted to be moved from the path of said foot by said primary lever, a movable bar connected with said secondary lever and a device adapted to be operated by said movable bar and grip the starting and stopping cable of the elevator and to be released therefrom.

707,812. AUTOMATIC CIRCUIT-CLOSER FOR TELEGRAPH-KEYS. JOHN R. FOLSOM, Mitchell, Ill. Filed Aug. 23, 1901. Serial No. 73,766. (No model.)



Claim.—1. The combination with a telegraph-key having a key-lever, of the binding-posts 9 attached to and extending upwardly from the key-lever, a circuit-closing lever 10 pivotally mounted between said binding-posts, the central portion of the circuit-closing lever being above and parallel with the key-lever and the forward end of the said circuit-closing lever being turned to the right, the set-screw 11 fixed in the forward end of the said circuit-closing lever and extending downwardly in position to contact with the manual circuit-closer, and a button upon the rear end of the said lever in position to be engaged by the operator when he grasps the key-lever button to operate the key, substantially as specified.

2. The combination with a telegraph-key, of binding-posts mounted upon and extending from the key-lever, a circuit-closing lever pivotally connected to the binding-posts, a spring in position to operate the circuit-closing lever, a set-screw in the forward end of the circuit-closing lever in position to make a contact and close the circuit and a button carried on the rear end of the circuit-closing lever, in position to be engaged by the operator when he operates the key substantially as specified.

3. The combination with a telegraph-key of a circuit-closing lever pivotally connected to the key-lever, a set-screw carried by the circuit-closing lever in position to make a contact and close the circuit, a button carried by the circuit-closing lever in position to be engaged by the operator when he operates the key, and a spring in position to hold the circuit-closing lever normally in its closed position, substantially as specified.

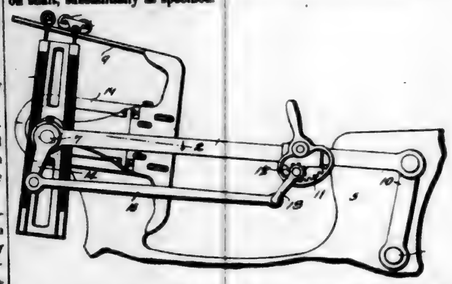
4. The combination with a telegraph-key of a circuit-closing lever pivotally connected to the key-lever, a set-screw carried by the circuit-closing lever in position to make a contact and close the circuit, a button carried by the circuit-closing lever in position to be engaged by the operator when he operates the key, and a spring in position to hold the circuit-closing lever normally in its closed position, and a manually-operated slide for holding the circuit-closing lever in its open position, substantially as specified.

707,813. ADJUSTABLE AND THROW-OFF ROLLER-TRACK FOR PRINTING-PRESSES. ADOLPH W. PEITZ, Burlington, Iowa. Filed Dec. 13, 1901. Serial No. 85,695. (No model.)

Claim.—1. The combination with a printing-press, of an impression-throw-off shaft having cam-grooves, and a frame arranged at each side of the press and adapted to be operated by said cam-grooves, each of such frames comprising a roller-track member and a carrying-plate connected thereto and means for adjustably securing the roller-track member and the carrying-plate to regulate the pressure of the inking-roller on the type.

2. In an attachment of the class set forth, comprising a rear plate having a forwardly-projecting tongue formed by reducing the outer portion of the plate, a track member provided with track extensions and having a socket to adjustably receive said tongue, and screw adjusting devices engaging portions of the said plate and track member.

3. An attachment of the class set forth, comprising a roller-track member guided at each side of the bed of the press, a plate, means for adjustably securing said plate to said roller-track member to regulate the respective planes of the roller-track member and the surface of the type, and means for operatively connecting said plate to the impression-throw-off shaft, substantially as specified.



4. The combination with inking-rollers and a form-bed, of guard devices at opposite sides of the form-bed, adjustable track attachments at opposite sides of the form-bed having slots to receive said guard devices, and means for causing the attachments to move forwardly and rearwardly.

5. The combination with a printing-press having an impression-throw-off shaft provided with cam-grooves, of a roller-track member situated at each side of the press and provided with horizontally-disposed slots, guiding bolts or screws adapted to said slots and carried by the frame of the press, a plate having its rear end adapted to the cam-groove, adjustable screws connecting the plate and track member, and means for connecting the plate and track member to prevent independent lateral movement, substantially as specified.

707,814. CABLE-SUPPORT. JONAH K. GAHALIELSON, Kaumana, Hawaii. Filed Aug. 24, 1901. Serial No. 73,141. (No model.)

Claim.—1. A support for cables comprising a head with a grooved edge lengthwise and a central opening for a support, and provided with an extension at one end, a cable resting on the upper edge of the head and extension and a clip over the cable locked on the extension and confining the cable on said support, substantially as described.

2. A supporting-head for cables having a head with a central hole and an arm in said hole on which the head is loosely mounted, said head having grooves lengthwise in its opposite edges and adapted to be reversed, and provided with an extension at one end constructed to receive a clip for confining a cable on said head, substantially as described.

3. The combination of the supporting-arm, the head rotatably mounted thereon at its center and having an extension at one end, a cable resting on the upper edge of the head and its extension and a clip engaged over the cable and the said extension and holding the cable in place, substantially as described.

707,815. BARB-WIRE MACHINE. HENRY GAUERMAN and DAVID PRYDE, Braddock, Pa. Filed Nov. 13, 1901. Serial No. 82,629. (No model.)

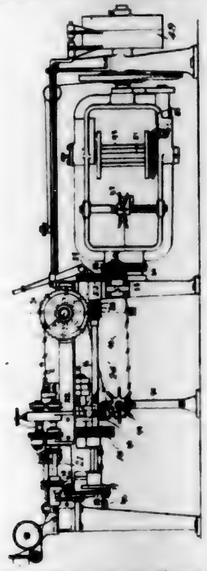
Claim.—1. In a barb-wire machine, a strand-feed mechanism, a rotary coiler, a main shaft carrying one or more offset or staggered threads, a worm-wheel meshing with the threads and driving the strand-feed mechanism, and rotary gearing on the main shaft for driving the coiler.

2. In a barb-wire machine, a strand-feed mechanism, a barb-wire-feed mechanism, a coiler, a main shaft carrying one or more offset or staggered threads and rotary gearing on said main shaft for driving the coiler, and connections from said main shaft for driving the barb-wire-feed mechanism.

3. In a barb-wire machine, a strand-feed mechanism, a rotary coiler, a main shaft carrying one or more offset or staggered threads, a worm-wheel meshing with the threads and driving the strand-feed mechanism, and gearing on the main shaft driving the coiler continuously in the same direction.

4. In a barb-wire machine, a coiler, stationary supports therefor, an independent slide, means for positively reciprocating the slide in both directions, and connections between the coiler and the slide.

5. In a barb-wire machine, a coiler, stationary supports therefor, an independent slide, means for positively reciprocating the slide in both directions, connections between the coiler and the slide, a strand-wire-feed mechanism, and a staggered thread for intermittently driving said mechanism.



6. In a barb-wire machine, a coiler, stationary supports therefor, a strand-wire-feed mechanism, a staggered thread for driving said mechanism, a barb-wire-feed mechanism, means for severing the barb-wire, an independent slide, means for positively reciprocating the slide in both directions, and connections between the coiler and the slide.

7. In a barb-wire machine, a sprocket-wheel for feeding the strand-wire, one or more threads for driving said wheel intermittently, and interchangeable gearing between the threads and the wheel for varying the speed of the latter

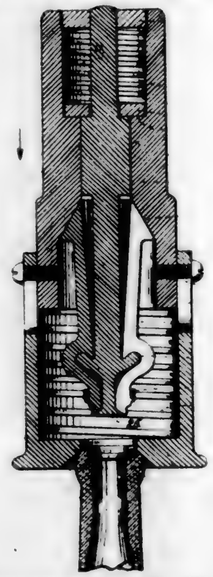
8. In a barb wire machine, a sprocket-wheel for feeding the strand-wire, a staggered worm for driving the sprocket-wheel intermittently, and means between the worm and the wheel for varying the speed of the latter consisting of a worm-wheel meshing with the worm, a spur-wheel rigid with the worm-wheel, a pinion rigid with the sprocket-wheel, and two removable wheels meshing with said spur-wheel and pinion.

9. In a barb-wire machine, a strand-wire-feed mechanism, a barb-wire-feed mechanism, a reciprocating and rotary coiler, a main shaft having an offset thread for intermittently driving the strand-wire-feed mechanism, and a gear-wheel connected to the coiler for reciprocating and rotating the same, and a pawl-and-ratchet connection between said shaft and said barb-wire-feed mechanism.

707,816. BOTTLE-SEALING MACHINE. HERMAN T. GAY, Baltimore, Md., assignor, by mesne assignments, to the Aluminum-Cork Seal Company, Camden, N. J., a Corporation of New Jersey. Filed May 13, 1901. Serial No. 59,916. (No model.)

Claim.—1. In a machine for expanding a sealing-plug of substantially the character described, in the mouth of a bottle, and compressing a joint-forming gasket between the said plug and a seat formed in the bottle-throat, a vertically-moving head comprising a central plunger having near its lower end a projecting annulus, a system of distensible jaws arranged around the said plunger, and fulcrumed on the said projecting annulus, adapted to enter the said sealing-plug, a shell situated exteriorly of the said plunger and the distensible jaws, the same having an inclined inner surface which, in the downward movement of the shell, independently of the jaws, serves to effect the distention of the portion of the jaws which are within the said plug, substantially as specified.

2. In a machine for expanding a sealing-plug of substantially the character described, in the mouth of a bottle, and compressing a joint-forming gasket between the said plug and a seat formed in the bottle-throat, a head comprising a central plunger having near its lower end a projecting annulus, a system of distensible jaws fulcrumed on the said annulus, the lower ends of the said jaws being adapted to enter the said sealing-plug, a spring device to yieldingly hold the lower ends of the said jaws in contact with the said central plunger, and means to effect the closing in of the upper ends of the said jaws, whereby the lower ends below the annular fulcrum are distended, substantially as specified.



3. In a machine for expanding a sealing-plug of substantially the character described, in the mouth of a bottle, and compressing a joint-forming gasket between the said plug and a seat formed in the bottle-throat, a centering device for the bottle, a centrally-supported annulus situated above the bottle-centering device the said annulus carrying a series of jaws with their lower ends adapted to enter the sealing device to be expanded, the said centering device and the plug-expanding jaws having a movement one toward the other, and means whereby the said jaws are diametrically contracted at a point above the annular fulcrum, and their lower ends thereby expanded, substantially as specified.

4. In a machine for expanding a sealing-plug of substantially the character described, in the mouth of a bottle, and compressing a joint-forming gasket between the said plug and a seat formed in the bottle-throat, a head comprising a shell having an inclined inner surface, a bottle-centering sleeve connected to the lower end of the said shell and adapted to have a vertical movement independently of the same, a spring to retain the said shell and the bottle-centering sleeve in a distended position one with the other, a plunger susceptible of a sliding movement within the said shell and which extends into the said sleeve, having near its lower end a projecting annulus, a system of jaws fulcrumed to the said annulus with their lower ends provided with a spring-band to keep them normally in a contracted condition and cause their upper ends to stand away from the inclosed plunger, the said upper ends being exteriorly beveled to correspond with the beveled surface in the said shell, a follower and a spring to yieldingly hold the said plunger in its lowest position with reference to the said shell, substantially as specified.

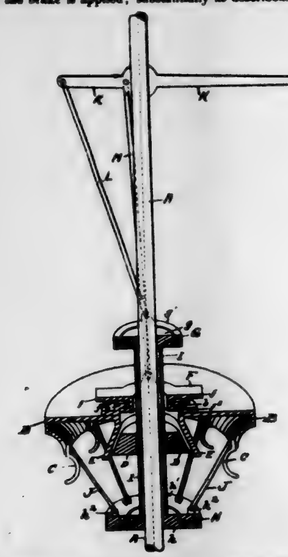
707,817. ROD-REEL. BURTON H. GUNDE, Anderson, Ind. Filed Apr. 26, 1900. Serial No. 14,253. (No model.)

Claim.—1. A rod-reel having a friction-wheel secured to the driven shaft, a vertically-movable friction-ring having the same axis as and arranged to connect with and be driven by the said wheel, hook-shaped fingers arranged to receive the rod, and connections between the fingers and the friction-ring arranged to move them in and out upon its vertical movement; substantially as described.

2. A rod-reel having a friction-wheel secured to a driven shaft, a vertically-movable friction-drum arranged to contact with the friction-wheel and be driven thereby, a friction brake-wheel arranged to contact with the friction-drum and raise and lower it, and means for moving the brake-wheel vertically; substantially as described.

3. A rod-reel having a series of outwardly-movable hook-fingers, a brake arranged to stop the rotation of the reel, and actuating connections

between the brake and the hook-fingers arranged to retract the fingers whenever the brake is applied; substantially as described.



4. The combination in a rod-reel, of a vertical driven shaft; a friction-wheel rigidly attached thereto, a friction-ring adapted to engage the friction-wheel and so mounted as to be capable of vertical movement; a coiling-drum connected with the friction-ring; coiling-hooks mounted on the drum; connections between the hooks and a slidable collar on the shaft; means for raising the friction-ring and drum; and means for simultaneously raising the collar on the shaft to withdraw the hooks; substantially as described.

5. The combination in a rod-reel, of a vertical driven shaft; a friction-wheel rigidly attached thereto; a friction-ring adapted to engage the friction-wheel and so mounted as to be capable of vertical movement; a coiling-drum connected with the friction-ring; braking and lifting members connected with the friction-ring; a brake-wheel adapted to engage the braking and lifting members; coiling-hooks mounted on the drum; connections between the hooks and a slidable collar on the shaft; means for raising the brake-wheel; and means for simultaneously raising the collar on the shaft to withdraw the hooks, substantially as described.

6. The combination in a rod-reel, of shaft A; friction-wheel D; friction-ring E; coiling-drum B; hooks C; brake-wheel F; collars G and H; rods I; links J; lever K and links L and M, substantially as described.

707,318. **PRESSURE-REDUCER FOR GAS OR OTHER PIPES.** JOHN L. GETZE and ROBERT A. PRIME, Cincinnati, Ohio. Filed Apr. 14, 1902. Serial No. 102,799. (No model.)

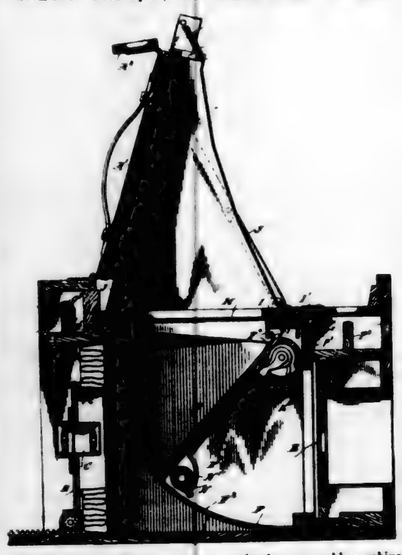
Claim.—1 A pressure-reducing device for gas-pipes and the like comprising a shell or casing having end portions adapted for connection with gas-pipe sections and having a tapered bore, a hollow body portion exteriorly tapered to fit the bore of the shell or casing and having an end portion extended beyond one end of the shell or casing, said body portion having a hollow adapted to receive a packing of fibrous material and having openings at its ends for the passage of gas through said hollow, a sheet of foraminous material extended across one end of said body portion to hold the packing in the hollow thereof and a cup-shaped valve movably held on the extended end of the body portion and arranged to control the opening at the other end of said body portion, substantially as set forth.

2. A pressure-reducing device for gas-pipes and the like comprising a shell or casing having end portions adapted for connection with gas-pipe sections and having a tapered bore, a hollow body portion exteriorly tapered to fit in the bore of the shell or casing and having one end open and having at its other end an end wall formed with a cut-out portion for the passage of gas and a valve held to turn on said last-named end of the body portion and having a wall formed with a cut-out portion adapted for registry with the cut-out portion of the end wall of said body portion, substantially as set forth.

3. In a pressure-reducing device for gas-pipes and the like, the combination of a shell or casing having ends adapted for connection with pipe-sections and having a tapered bore, a body portion tapered to fit the bore in said shell or casing and having a gas-passage formed in it and provided with pressure-reducing means, and means for holding said body portion in position in said bore, substantially as set forth.

4. In a pressure-reducing device for gas-pipes and the like, the combination of a shell or casing having ends adapted for connection with pipe-sections and having a passage formed through it, one portion of said passage being reduced and made tapered and having a shoulder extended around its larger end, a body portion having a gas-passage formed in it and provided with pressure-reducing means, said body portion being exteriorly tapered to fit in the conical bore of the shell or casing and a sheet of foraminous material extended across the larger portion of the passage of the shell or casing at the end of said body portion with edge portions rested on the shoulder of said passage, said sheet being arranged to hold the body portion in place in the shell or casing, substantially as set forth.

707,319. **PHOTOGRAPHIC CAMERA.** HENRY W. HALSE, Ridgewood, N. J. Filed Sept. 5, 1901. Serial No. 74,387. (No model.)



Claim.—1. A photographic camera, having a movable combination mirror and shutter, and an air-chamber located at one side of the shutter-pivot and having a passage that communicates with the mirror and shutter chamber, for relieving air-pressure when imparting a swinging motion to the mirror and shutter, as set forth.

2. A photographic camera having a pivoted swinging shutter, and an air-outlet chamber O located as shown and provided with a passage o' that communicates with the shutter-chamber at a point below the limit of movement of the shutter as shown, whereby the air issues rapidly in the initial movement of the shutter but a portion is confined between the shutter and the side of the chamber just before the movement of the shutter is completed, as shown and described.

3. A photographic camera, having a movable shutter, and air-chambers opening to the outside for relieving the shutter of air-pressure when moving the shutter into an open or a closed position, as set forth.

4. A photographic camera, having a movable shutter, and air-chambers opening to the outside for relieving the shutter of air-pressure when moving the shutter into an open or a closed position, the said air-chambers having means for preventing rays of light from passing to the interior of the camera-casing, as set forth.

5. A photographic camera, having a movable shutter, and a safety-curtain for the shutter, which is extensible and attached to the outer end of the shutter and has an initial movement relative to that of the shutter, as set forth.

6. A photographic camera, having a movable shutter, and a safety-curtain for the shutter, which is attached to the outer end of the shutter and extensible as specified and arranged to regulate the size of the shutter-opening, as set forth.

7. A photographic camera, having a swing-shutter, a mirror carried thereby, a safety-curtain carried by the said swing-shutter and supported and arranged transversely on the outer end of the shutter and adapted for extension as specified, and means for moving the safety-curtain into a closed position previous to starting the said shutter, as set forth.

8. A photographic camera, having a swing-shutter, a mirror carried thereby, a safety-curtain carried by and arranged transversely upon the outer free end of the swing-shutter, means for moving the safety-curtain into a closed position previous to starting the said shutter, and to release the safety-curtain at the option of the operator after the shutter is moved into a set position, as set forth.

9. A photographic camera, comprising a casing having a segmental apertured partition, a segmental swing-shutter in the said casing and having its aperture adapted to register with the aperture in the partition, and an adjustable safety-curtain carried by the said shutter and arranged transversely upon the outer free end of the shutter and adapted for independent adjustment thereon to allow of regulating the size of the shutter-aperture, as set forth.

10. A photographic camera, comprising a casing having a segmental apertured partition, a segmental swing-shutter in the said casing and having its aperture adapted to register with the aperture in the partition, an adjustable safety-curtain carried by the said shutter and independently adjustable thereof to allow of regulating the size of the shutter-aperture, and means for imparting an initial movement to the curtain previous to swinging the shutter into a set position to close the shutter-opening while moving the shutter into a set position, as set forth.

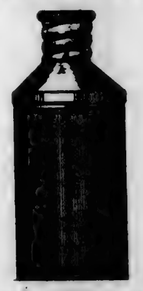
11. A photographic camera, having a spring-pressed swing-shutter, a sleeve on which the shutter is mounted to swing loosely, the sleeve having an arm for imparting a swinging motion to the shutter, a safety spring-roller curtain journaled on the shutter, and an arm carried by the said sleeve and connected with the said curtain, as set forth.

12. A photographic camera, having a spring-pressed swing-shutter, a sleeve on which the shutter is mounted to swing loosely, the sleeve having an arm for imparting a swinging motion to the shutter, a safety spring-roller curtain journaled on the shutter, an arm carried by the said sleeve and connected with the said curtain, and a cam device under the control of the operator for setting the said arm and sleeve, as set forth.

13. In a photographic camera, the combination, with the casing and the cover hinged thereto, of a hood formed of flexible material and an eyepiece which is secured to its outer edge and free from and movable independently of the cover, and springs connecting the eyeplate with the cover and serving as the sole support for the eyepiece and means for stretching the hood, as shown and described.

14. In a photographic camera, the combination, with the movable cover and flexible focusing-hood provided at its outer end with an eyepiece which is adapted to slide parallel to the cover, of yielding supports for said eyepiece which are connected with the free end of the cover whereby the said parts are adapted to operate as shown and described.

707,320. **SCREW-CAP CLOSURE.** HENRY J. S. HALL, New York N. Y. Filed Feb. 12, 1902. Serial No. 93,740. (No model.)



Claim.—1. A closure formed by a screw-threaded nozzle constructed with an outlet in its front near its lower end and provided with a stop above the plane of said outlet, and an imperforate screw-cap having an inwardly-projecting stop to engage with said stop on the nozzle when the outlet is fully opened.

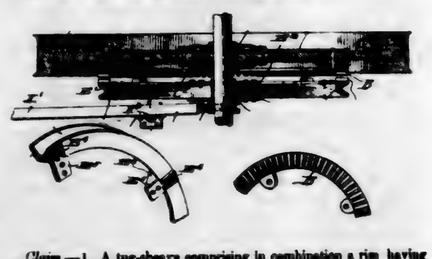
2. A closure formed by a screw-threaded nozzle constructed with an outlet in its front near its lower end and provided with a stop above the plane of said outlet, and an imperforate screw-cap having an inwardly-projecting stop at its lower edge to engage with said stop on the nozzle when the outlet is fully opened.

3. A closure formed by a screw-threaded nozzle constructed with an outlet in its front near its lower end and provided with a stop above the plane of said outlet, and an imperforate screw-cap having an inwardly-projecting stop integral with the body of the cap to engage with said stop on the nozzle when the outlet is fully opened.

4. The combination, in a powder-box, of a suitable body, a cover for the same having a conical top and a screw-threaded nozzle having an outlet in its front near its lower end and provided with a stop on its outer surface above the plane of said outlet, and an imperforate screw-cap having its lower edge provided with a stop to engage with said stop on the nozzle when the outlet is fully opened, and adapted to close powder-tight against said conical top.

5. The combination, in a powder-box having a screw-cap closure of a suitable body having its front designated, a cover, inseparably attached to said body, having a screw-threaded nozzle provided with a closed upper end and an outlet in its front near its lower end, and a screw-cap inclosing said closed upper end; said nozzle and said cap being provided respectively with stops arranged to engage each other when the outlet is fully opened and to prevent the removal of the cap, substantially as hereinbefore specified.

707,321. **TUG SHEAVE-CLUTCH.** HIRAM B. HARDING, Los Angeles, Cal. Filed Oct. 19, 1901. Serial No. 79,230. (No model.)



Claim.—1. A tug-sheave comprising in combination a rim having a circumferential groove and provided with clutch-teeth at regular intervals, said rim having sockets, the spokes having their outer ends secured in said sockets the hub to which the inner ends of said spokes are attached, said hub having a circumferential groove, a shifting-lever adapted to fit said groove and the hand-wheel provided with clutch-teeth, substantially as described.

2. A tug-sheave comprising in combination a rim having a circumferential groove and provided with clutch-teeth upon the inner face of said rim at regular intervals, the inwardly-projecting ears or lugs integral with the rim and in alinement with the clutch-teeth, the parallel flanges connecting the rim and ears or lugs thereby providing sockets, the spokes shouldered at their outer ends and fitting into the said sockets and embracing the edge of the rim, the hub formed with a collar to which the inner ends of the spokes are secured, and the hand-wheel provided with clutch-teeth, substantially as shown and described.

707,322. **GALVANIZING-MACHINE.** RICHARD HEATHFIELD, London, England. Filed Feb. 24, 1902. Serial No. 96,446. (No model.)

Claim.—1. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls wholly submerged in the molten metal, and a pair of exit-rolls partially submerged in the molten metal, the clearing-rolls being arranged below and in close proximity to the exit-rolls in order that after the submerged rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, substantially as described.

2. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls wholly submerged in the molten metal, and a pair of exit-rolls submerged up to the nip in the molten metal, the clearing-rolls being arranged below and in close proximity to the exit-rolls in order that after the submerged rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, substantially as described.

3. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls, wholly submerged in the molten metal, and a pair of exit-rolls partially submerged in the molten metal, the clearing-rolls being arranged below and in close proximity to the exit-

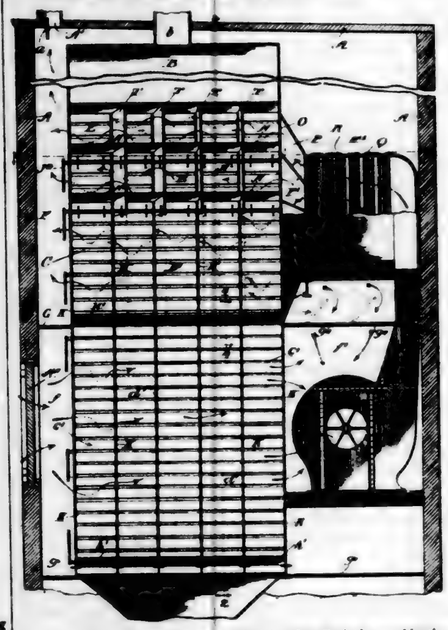
rolls in order that after the submerged rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, and guides arranged between the pair of clearing-rolls substantially as described.

4. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls wholly submerged in the molten metal, and a pair of exit-rolls partially submerged in the molten metal, and frames arranged on the bath and supporting said pairs of rolls, the said clearing-rolls being arranged below and in close proximity to the exit-rolls in order that after the clearing-rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, and guides arranged between the pair of clearing-rolls and the pair of exit-rolls, and upper and lower sets of guides leading to the clearing-rolls, the upper set of which guides is fixed to the frames supporting the rolls and the lower set of which is at one end supported on the edge of the bath and at the other end is hooked over a tie-bar passing between the frames supporting the pairs of rolls, substantially as described.

5. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls wholly submerged in the molten metal, and a pair of exit-rolls partially submerged in the molten metal, and frames arranged on the bath and supporting said pairs of rolls, the said clearing-rolls being arranged below and in close proximity to the exit-rolls in order that after the clearing-rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, and a set of guides arranged between the two pairs of rolls on each side of the path of the sheet undergoing galvanization, each set being provided with and supported by hooks hooked over tie-bars passing between the frames supporting the pairs of rolls, substantially as described.

6. In a galvanizing-machine, the combination of a bath containing molten metal, a pair of clearing-rolls wholly submerged in the molten metal, and a pair of exit-rolls partially submerged in the molten metal, and frames arranged on the bath and supporting said pairs of rolls, the said clearing-rolls being arranged below and in close proximity to the exit-rolls in order that after the clearing-rolls have cleared away superfluous metal from the sheet undergoing galvanization, the sheet may pass through as little molten metal as possible, and a set of guides arranged between the two pairs of rolls on each side of the path of the sheet undergoing galvanization, each set being provided with and supported by hooks hooked over tie-bars passing between the frames supporting the pairs of rolls, and upper and lower sets of guides leading to the clearing-rolls, the upper set of which guides is fixed to the frame supporting the rolls and the lower set of which is at one end supported on the edge of the bath and at the other end is hooked over a tie-bar passing between the frames supporting the pairs of rolls, substantially as described.

707,823. APPARATUS FOR DRYING, COOLING, OR OTHERWISE TREATING GRAIN, &c. GEORGE H. HESS, Jr., Chicago, Ill. Filed Jan. 24, 1901. Serial No. 44,092. (No model.)



Claim.—1. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side and having in their sides openings for the passage of air, a supply-chamber between said racks, said chamber being open at one end for the admission of air, means for causing a blast of air to enter said chamber horizontally, and a vertical baffle within the chamber for deflecting the air outward toward the racks, substantially as described.

2. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side and having in their sides openings for the passage of air, a supply-chamber between said racks, said chamber being open at its end for the admission of air, a fan for causing a blast of air to enter said chamber horizontally, and an upright baffle located within the chamber equidistant from the racks for deflecting the air outward toward the racks, substantially as described.

3. In an apparatus of the class described, the combination of a pair of upright grain-racks having in their sides openings for the passage of air and having uprights dividing them into separate vertical sections, a supply-chamber between said racks, said chamber being open for the admission of air, means for causing a blast of air to enter said chamber, and a series of baffles arranged in said chamber opposite the uprights for deflecting the air outward toward the racks, substantially as described.

4. In an apparatus of the class described, the combination of a pair of upright grain-racks having in their sides openings for the passage of air, a supply-chamber between said racks, said chamber being open for the admission of air, means for causing a blast of air to enter said chamber, and a reticulated diaphragm in the path of the entering air, substantially as described.

5. In an apparatus of the class described, the combination of an upright grain-rack having in its sides openings for the passage of air, a supply-chamber located at one side of said rack, a horizontal valve dividing the rack into a plurality of separate horizontal sections, a horizontal bulkhead dividing the supply-chamber into a plurality of horizontal sections corresponding with those of the rack, means common to all of said sections for heating air, means for causing a blast of the heated air to pass from said chamber into and through all of the several sections of the rack in the same direction, and separate means for controlling the passage of air into the separate sections of the chamber, substantially as described.

6. In an apparatus of the class described, the combination of an upright grain-rack having in its sides openings for the passage of air, a supply-chamber located at one side of the rack, a horizontal valve dividing the rack into a plurality of separate horizontal sections, a bulkhead dividing the supply-chamber into a plurality of horizontal sections corresponding with the sections of the rack, means common to all of said sections for heating air, separate flues leading therefrom and communicating with the separate sections of the supply-chamber, respectively, separate valves in said flues, and means for causing a blast of air to pass from the heater into the supply-chamber and thence into and through all of the several sections of the racks in the same direction, substantially as described.

7. In an apparatus of the class described, the combination of an upright grain-rack having in its sides openings for the passage of air, a horizontal valve dividing the rack into a heating-section and a cooling-section, a valve located at the bottom of the cooling-section, a valve located between the top and bottom of the cooling-section, and dividing it into a plurality of separate horizontal sections, a valve between the top and bottom of the heating-section and dividing it into a plurality of separate horizontal sections, means for causing a blast of cold air to pass through all parts of the cooling-section of the rack in the same direction, and means for causing a blast of heated air to pass through all parts of the heating-section of the rack in the same direction, substantially as described.

8. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side, having in their sides openings for the passage of air, a supply-chamber located between said racks, horizontal valves dividing the racks into a plurality of separate horizontal sections, means common to all of said sections for heating air and means for causing a blast of the heated air to pass through all of the several sections of each of the racks in the same direction, substantially as described.

9. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side having in their sides openings for the passage of air, horizontal valves dividing said racks into a plurality of separate horizontal sections, a supply-chamber located between the racks, a bulkhead located in the supply-chamber and dividing it into a plurality of horizontal sections corresponding with the sections of the racks, means common to all of said sections for heating air and means for separately supplying said sections of the supply-chamber with the heated air and causing it to pass through all of the several horizontal sections of each of the racks in the same direction, substantially as described.

10. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side having in their sides openings for the passage of air, horizontal valves dividing said racks into a plurality of separate horizontal sections, a supply-chamber located between the racks, a plurality of bulkheads dividing the supply-chamber into a plurality of separate horizontal sections corresponding with the sections of the racks, a separate air-flue communicating with each of said sections of the supply-chamber, means for separately controlling each of said flues, means common to all of said sections for heating air, and means for causing a blast of the heated air to pass through said flues and into the separate sections of the supply-chamber and thence through all of the several sections of each of the drying-racks in the same direction, substantially as described.

11. In an apparatus of the class described, the combination of a pair of upright grain-racks arranged side by side having in their sides openings for the passage of air, horizontal valves dividing the racks into heating-sections and cooling-sections, a housing inclosing the racks, means located at about the level of said valves and dividing the interior of the housing into compartments corresponding respectively with the heating-sections and the cooling-sections of the racks, horizontal valves dividing the heating-sections of the racks into a plurality of separate horizontal sections, horizontal valves dividing the cooling-sections of the racks into a plurality of separate horizontal sections, a supply-chamber located between the heating-sections of the racks, a supply-chamber located between the cooling-sections of the racks, exhaust-chambers located upon opposite sides of the heating-sections of the racks, exhaust-chambers located upon opposite sides of the cooling-sections of the racks, means for causing a blast of air to enter the supply-chamber of the cooling-sections and pass thence through all of said cooling-sections of each rack in the same direction and thence into the exhaust-chambers at the sides thereof, thence to the supply-chamber of the heating-sections of the racks, thence through all of said sections of each of the racks in the same direction and thence into the exhaust-chambers at the sides thereof, and means for heating the air in transit between the cooling and heating sections, substantially as described.

12. In an apparatus of the class described, a grain-rack comprising a plurality of uprights, each having two vertical rows of flanges, the flanges of the two rows being staggered, a plurality of slats permanently secured to the flanges of one row, and a plurality of slats resting upon the flanges of the other row and having hooks engaging said flanges, substantially as described.

13. In an apparatus of the class described, the combination of a pair of grain-racks, each having a plurality of slats, a chamber between said racks, and a horizontal bulkhead closing said chamber and supported by the slats of the rack, substantially as described.

14. In an apparatus of the class described, the combination of a pair of grain-racks, each having a plurality of slats, and a chamber between said racks, a horizontal bulkhead of inverted-V shape in cross-section closing said chamber and supported by the slats of the rack, substantially as described.

15. In an apparatus of the class described, the combination with a grain-rack having two vertical rows of staggered slats, of a valve mounted to move adjacent to the lower edge of a slat of one row and opposite an intermediate part of an adjacent slat of the other row, substantially as described.

16. In an apparatus of the class described, the combination with a grain-rack having two vertical rows of staggered slats, of a valve mounted to move adjacent to the lower edge of a slat of one row and opposite an intermediate part of an adjacent slat of the other row, and a shield located inside of the latter slat and terminating at its lower edge in close proximity to the valve, substantially as described.

17. In an apparatus of the class described, the combination with a grain-rack having a pair of uprights, of a valve mounted to slide between said uprights, flanges projecting from the uprights and extending over the ends of the valve, and flanges carried by the uprights and supporting the valve, substantially as described.

18. In an apparatus of the class described, the combination with a grain-rack having a pair of uprights, of a valve mounted to slide between said uprights, flanges projecting from the uprights and extending over the ends of the valve, and flanges carried by the uprights and supporting the valve, said flanges being provided with openings for the escape of grain, substantially as described.

19. In an apparatus of the class described, the combination with a plurality of grain-racks, of a plurality of heating-drums, a radiator in each of said heating-drums, and a header common to said radiators, substantially as described.

20. In an apparatus of the class described, the combination with a plurality of grain-racks, of a plurality of heating-drums, separate radiating-pipes in said drums, a header common to the radiating-pipes of said drums, and means for supplying said header with steam, substantially as described.

21. In an apparatus of the class described, the combination with a plurality of grain-racks, of a plurality of drums, a radiator in each of said drums, a header common to said radiators, a central inlet for steam, and a diaphragm dividing the header, substantially as described.

707,824. LAWN-MOWER. WILLIAM H. H. HEYDRICK, Philadelphia, Pa. Filed Apr. 20, 1901. Serial No. 56,126. (No model.)

Claim.—1. In a lawn-mower a cutting mechanism a sweeper located in advance of said cutting mechanism and elevated to be out of contact with the ground, a receptacle in advance of said sweeper and means for revolving said sweeper which latter is adapted to deflect the weeds, &c., to the cutting mechanism and receive the cut weeds, &c., and discharge the same into said receptacle.

2. In a lawn-mower, a frame, a shaft mounted therein, a cutting mechanism carried by said shaft, a brush disposed above the point of action of the cutting mechanism to deflect the grass, &c., thereto a receptacle in advance of the cutting mechanism a brush-actuating mechanism connected with said shaft means connected with said actuating mechanism for rotating said brush and rollers located under the brush and supported from said frame.

3. In a lawn-mower, a cutting mechanism, a receptacle located in advance of the said cutting mechanism, a sweeper located intermediate of said cutting mechanism and receptacle, and means for rotating said sweeper which latter is adapted to deflect the weeds and the like to said cutting mechanism and to receive the cut weeds and the like from said cutting mechanism and discharge the same into said receptacle.

4. The combination in a lawn-mower, of a framework, cutting mechanism mounted therein, a brush rotatably mounted in advance of said cutting mechanism, rollers located under said brush for supporting the same, a hood located over said cutting mechanism and brush, arms projecting

forwardly from said framework and a receptacle for the cut grass mounted on said arms.

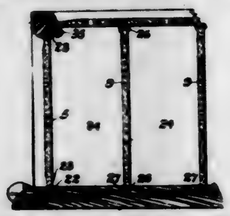
5. In a lawn-mower, a cutting mechanism, a receptacle in advance of said cutting mechanism a sweeper intermediate of said cutting mechanism and said receptacle, means for rotating said sweeper, and a guard located over said cutting mechanism and said sweeper to deflect the cut grass into said receptacle.

6. In a lawn-mower, cutting mechanism, a sweeper located in advance thereof, a receptacle in advance of the cutting mechanism and extending above the same and a guard located over said cutting mechanism and said sweeper.

7. In a lawn-mower, a cutting mechanism, a receptacle in advance of said cutting mechanism and a brush located between said cutting mechanism and said receptacle which is adapted to be rotated and which depresses the grass and the like to the cutting mechanism and is adapted to convey the cut grass and the like from the cutting mechanism to the receptacle.

8. In a lawn-mower, a cutting mechanism, a receptacle in advance of said cutting mechanism, a brush located between said cutting mechanism and said receptacle, and constructed and arranged to depress the grass and guide it to the cutting mechanism and to assist in throwing the cut grass into said receptacle, and a hood extending over said cutting mechanism and said brush.

707,825. COMPARTMENT-BOX FOR CHECKS OR THE LIKE. JOHN T. KING, Boston, Mass. Filed Mar. 6, 1902. Serial No. 96,927. (No model.)

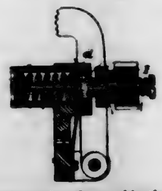


Claim.—1. In a compartment-box, the combination with the base and skeleton frame thereon, of the front plate, the lower edge of which enters a grooved strip of rubber lying in a groove in the base while the upper edge engages a rabbet in the frame, and is provided with a grooved strip of rubber having a series of slots said rabbet in the frame having an inclined face for making a tight joint, and a series of transparent partitions engaging the aforesaid slots in the rubber strip.

2. The combination with the grooved base, and the frame mounted thereon, of the front plate having strips of grooved rubber on the edges, the strip on its top edge having a series of slots, the top plate having strips of grooved rubber on the edges, the end plates likewise provided with strips of grooved rubber, and the glass partitions having strips of grooved rubber at top and bottom, said partitions engaging the slots in the rubber strip on the front plate.

3. The combination with the grooved base, and the skeleton frame thereon, of the top and plates, the front plate having on its upper edge a grooved strip of rubber provided with a series of slots, the series of transparent partitions which subdivide the box into compartments, said partitions engaging the aforesaid slots in the rubber, and the removable slide.

707,826. GRIP-CARRIER FOR BUTTON-MAKING MACHINES. JOHN HORNBY, Woonsocket, R. I. Filed Apr. 4, 1902. Serial No. 101,436. (No model.)



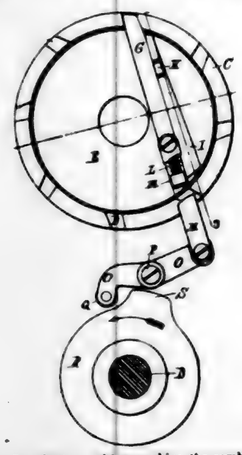
Claim.—1. In a grip-carrier, the combination with a fixed jaw of a movable jaw composed of a plurality of separately-movable members, of means for moving said members simultaneously but independently toward said fixed jaw, with a yielding pressure.

2. In a grip-carrier, the combination with a fixed jaw of a movable jaw composed of a plurality of separately-movable members, of means for moving said members simultaneously but independently toward said fixed jaw, with a yielding pressure, said means consisting of a pinion mounted upon a screw, a universally-jointed bearing intermediate the pinion and the members of the movable jaw and a spring acting against the pressure of the pinion.

3. In a grip-carrier the combination with a fixed jaw, of a movable jaw consisting of separate members, means for opening and closing the jaws consisting of a pinion mounted upon a screw, a spring acting against the thrust of the pinion, and bearing-pieces interposed between the pinion and the movable jaw adapted to freely oscillate with relation to the jaw, the pinion and each other.

4. In a grip-carrier, the combination with a fixed jaw and a movable jaw consisting of separate members, of means for opening and closing the jaws consisting of a screw, means for moving it yieldingly in the direction of the closing of the jaws, means for moving it positively in the opposite direction and a universally-jointed bearing between the positive means and the movable jaw.

707,827. LOCKING DEVICE FOR WORK-CARRIERS. JOHN HORNBY, Woonsocket, R. I. Filed Apr. 4, 1902. Serial No. 101,437. (No model.)



Claim.—1. In a button-making machine, the combination with the intermittently-rotating turret and a notched ring carried thereby, of a stationary disk in the notched ring provided with a transverse groove which registers *coincides* with the notches, a locking-bolt supported throughout its length in said groove, and means for causing the bolt to automatically engage in the notches of the ring.

2. In a button-making machine, the combination with the intermittently-rotating turret, and a notched ring carried thereby, of a stationary disk in the notched ring provided with a transverse groove which registers *coincides* with the notches, a locking-bolt supported throughout its length in said groove, means for causing the bolt to automatically engage the notches when they register with the groove, and means for withholding the bolt from the notches while the turret is in motion.

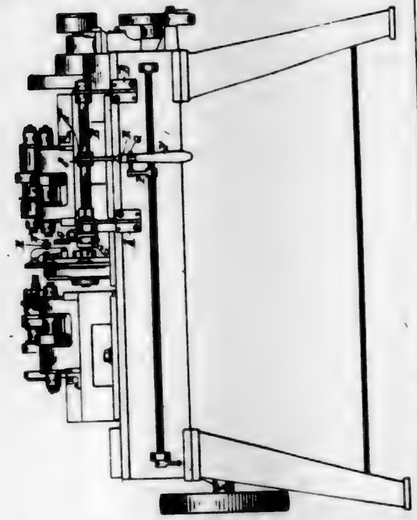
3. In a button-making machine, the combination with the intermittently-rotated turret, and a notched ring carried thereby, of a stationary plate within said ring and transversely grooved, a locking-bolt in said groove normally spring-pressed into said notches *coincides*, a cam-shaft parallel to the axis of rotation of the turret, a cam-disk on said shaft, and connections between the cam-disk and bolt whereby the latter is withdrawn from the notches after each period of rest of the turret.

707,828. SEGMENTAL GEAR FOR BUTTON-MAKING MACHINES. JOHN HORNBY, Woonsocket, R. I. Filed Apr. 4, 1902. Serial No. 101,438. (No model.)

Claim.—1. In a button-making machine the combination with a grip-tightening screw and a pinion thereon, of a driving-gear, intermeshing with the pinion, and means for moving said driving-gear toward the grip-pinion in substantially the direction of a radius of the latter.

2. In a button-making machine the combination with a grip-tightening screw and a pinion thereon, of a driving-gear intermeshing with the pinion and means for moving said driving-gear away from the grip-pinion in substantially the direction of a radius of the latter.

3. In a button-making machine the combination with a grip-tightening screw, and a pinion thereon, of a driving-gear intermeshing with the pinion, and means for moving the driving-gear toward and away from the grip-pinion in substantially the direction of a radius of the latter.



4. In a button-making machine the combination with a grip tightening and releasing screw and a pinion thereon, of a driving-gear intermeshing with the pinion and means for moving the driving-gear toward the axis of rotation of the grip-pinion at the beginning of the releasing movement.

5. In a button-making machine, the combination with a grip tightening and releasing screw and a pinion thereon, of a driving-gear intermeshing with the pinion, and means for moving the driving-gear away from the axis of rotation of the pinion at the end of the tightening movement.

6. In a button-making machine, the combination with a grip tightening and releasing screw and a pinion thereon, of a driving-gear intermeshing with the pinion, means for moving the driving-gear away from the axis of rotation of the pinion at the end of the tightening movement and in the opposite direction at the beginning of the releasing movement.

7. In a button-making machine, the combination with a grip tightening and releasing screw, of a shaft parallel with the screw, eccentric bushings serving as bearings for the shaft, a driving-gear carried by the shaft, and means whereby the bushings are slightly rotated at the beginning of the releasing movement in a direction to move the shaft and driving-gear nearer to the axis of rotation of the pinion.

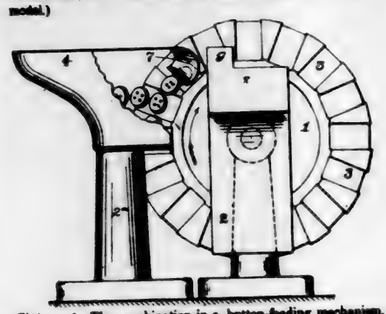
8. In a button-making machine, the combination with a grip-tightening screw and a pinion thereon, of a shaft parallel with the screw, eccentric bushings serving as bearings for the shaft, a driving-gear carried by the shaft, and means whereby the bushings are slightly rotated at the ending of the tightening movement in a direction to carry the shaft and driving-gear away from the axis of rotation of the pinion.

9. In a button-making machine, the combination with a grip tightening and releasing screw, and a pinion thereon, of a shaft parallel with the screw, eccentric bushings serving as bearings for the shaft, a driving-gear on the shaft, and means whereby the bushings are slightly turned to move the shaft and driving-gear toward the axis of rotation of the pinion at the beginning of the releasing movement and in the opposite direction at the end of the tightening movement.

10. In a button-making machine, a grip releasing and tightening mechanism comprising a shaft, a segmental gear thereon, a friction-collar on the shaft provided with a pair of lugs, an eccentric bushing serving as a bearing for the shaft, said bushing having a lateral lug projecting between the lugs of the collar and with a recessed flange, and a pin projecting from the shaft into the recess of the flange of the bushing.

11. In a button-making machine, the combination with a horizontal rock-shaft, a segmental gear and a hand-lever projecting therefrom on opposite sides, a parallel rock-shaft, an arm thereon, a lateral bar on said arm in the path of movement of the hand-lever, and a spring-pin projecting from the arm arranged to contact with the frame of the machine to keep the hand-lever off the bar.

707,829. BUTTON-FEEDING MECHANISM. JOHN HORNBY, Woonsocket, R. I. Filed Apr. 12, 1902. Serial No. 102,843. (No model.)



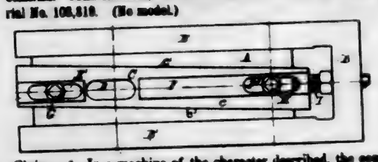
Claim.—1. The combination in a button-feeding mechanism, of a runway, a frustum of a cone mounted to rotate on a horizontal axis and provided with grooves in its external periphery each of which is parallel with the runway when at the point of delivery, a hopper one side of which is formed by the face of the frustum, and a guard projecting from, and in the plane of the top of, the hopper with its end tangential to the grooved external surface of the frustum.

2. A button-feeding mechanism comprising a runway, and a conic frustum mounted to rotate upon a horizontal axis and provided with grooves in its external surface each of which is parallel with the runway when at the point of delivery, in combination with a hopper one side of which is formed by the face of the frustum, a guard projecting from the top of the hopper and whose outer surface is parallel with the external surface of the frustum, and a runway-plate placed in front of the smaller side of the frustum and provided with a projecting guard whereby the buttons are retained upon the conic frustum until the point of delivery is reached.

3. A button-feeding mechanism comprising a conic frustum provided with button-receiving grooves in its face and mounted to rotate on a horizontal axis, a hopper by the side of the frustum having the side adjacent to the face of the frustum open whereby the contents of the hopper lie on said surface of the frustum, and an elastic guard upon the top of the hopper projecting over the face of the frustum having its end turned under and backward with the edge thereof parallel to the grooves of the frustum when passing under it, said edge being normally at the proper distance from the frustum to permit of the passage of only one button at a time and in its proper position.

4. A button-feeding mechanism comprising a grooved conic frustum mounted to rotate upon a horizontal axis, a hopper of a width equal to the thickness of the frustum located adjacent to one side of said frustum, and having the side next to the frustum open, a guard projecting from the hopper over the frustum into a position to permit of the passage of but one button at a time thereunder, a runway at the smaller end of the frustum in position to receive the buttons in the grooves of the frustum as they reach their uppermost position, and a guard projecting from the runway adjacent to the smaller end of the frustum into position to prevent the discharge of buttons from the grooves of the frustum while between the hopper and their uppermost positions.

707,830. SPINDLE ADJUSTMENT FOR BUTTON-MAKING MACHINES. JOHN HORNBY, Woonsocket, R. I. Filed Apr. 19, 1902. Serial No. 103,810. (No model.)



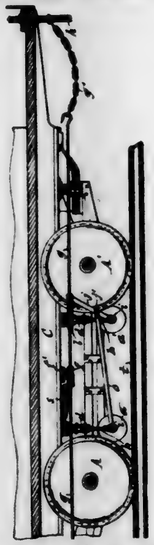
Claim.—1. In a machine of the character described, the combination with the spindle-bearing, of means for laterally adjusting it, said means consisting of a bar guided in the longitudinal plane of the head, and means for sliding said bar in a laterally-inclined groove in the bottom of the bearing.

2. In a machine of the character described, the combination with the spindle-bearing provided with a laterally-inclined groove in its bottom, of a bar fitted to slide in said groove, slots in the bar in the longitudinal plane of the bearing and bolts in said slots threaded into the bearing.

3. In a machine of the character described, the combination with the spindle-bearing provided with grooves at the edges of its bottom face having inclined top walls, of a block having wedge-shaped arms extending into said grooves, means for moving the block and arms longitudinally with relation to the bearing, and means for preventing lateral displacement of or strain upon the arms.

4. In a machine of the character described, the combination with the spindle-bearing provided with side grooves in its bottom having inclined top walls and an intermediate groove having laterally-inclined side walls, of wedge-shaped arms in the side grooves, a bar with parallel inclined sides in the intermediate groove, and means for adjusting the arms and bar longitudinally in lines parallel with each other and with the sides of the bearing.

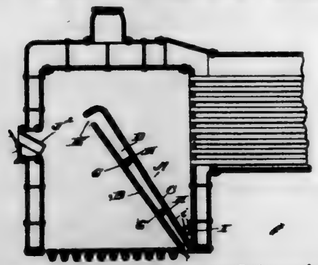
707,331. CAR-BRAKE. WILLIAM HOUSE, Syracuse, N. Y. Filed Jan. 16, 1902. Serial No. 89,935. (No model.)



Claim.—1. The combination, with a car-truck, of extensible hangers pivotally connected to the truck, springs contracting said hangers, rollers pivoted to the free ends of said hangers, and mechanism for imparting motion to the hangers to carry the rollers to and from simultaneous contact with the car-wheels and track as set forth.

2. The combination, with a car-truck, of hangers pivotally connected to said truck and movable vertically toward and from the track-rails, springs lifting said hangers, brake-rollers pivotally supported on the lower ends of said hangers, means for swinging the hangers toward and from the car-wheels, and a coupling transmitting simultaneous movement to the hangers as set forth.

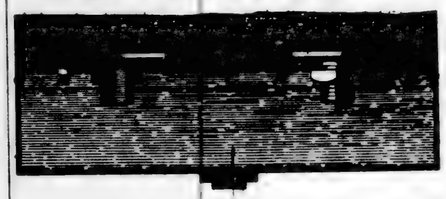
707,332. SMOKE AND SPARK PREVENTING DEVICE. WILLIAM S. HUSHER, Philadelphia, Pa., assignor to Edward A. Willard, New York, N. Y. Filed Jan. 7, 1902. Serial No. 88,712. (No model.)



Claim.—1. In a device of the character described, an arched structure arranged within the fire-box and extending entirely across the same, said structure composed of a front and rear wall commencing at the lower rear corner of the fire-box and extending upward and forward and terminating at a point above the line of the furnace-door, said walls so arranged as to form a gradually-widening passage in between the same, the narrowest portion being at the inlet and the widest portion being at the upper end, the forward wall being provided at the upper end with an opening, a series of nozzles secured to the forward wall and extending through the passage in between the walls, said nozzles being provided with openings therethrough, the rear wall having openings opposite the nozzles but of larger diameter than the same, a damper or valve arranged at the inlet end of the passage for regulating the supply of air, an opening formed through the furnace-door, a hood secured to the inner face of the door and projecting inward in a downwardly-inclined direction, substantially as and for the purpose specified.

2. In a device of the character described, an arched structure arising from the lower rear corner of the fire-box and inclined forward and terminating at a point above the furnace-door, a tapering air-passage formed in the structure, said passage opening through the bed of the fire-box, the structure provided with an opening at its upper end so arranged as to discharge the air slightly downward, a series of nozzles having openings formed longitudinally through the same secured to the forward portion of the structure and extending through the passage, the rearward portion of the structure being provided with openings registering with the nozzles but of larger diameter than the same, an opening formed through the furnace-door, a baffle-plate or hood arranged upon the interior for directing the air passing through the opening downward toward the fire-bed, a damper or supplementary door for regulating the inflow of air through such opening, a steam-pipe arranged in the angle between the rear of the structure and the rear fire-bed wall, said steam-pipe having openings formed in the upper portion thereof so as to eject the steam upward, as and for the purpose specified.

707,333. FILTER. CHURCHILL HUGGERFORD, Philadelphia, Pa. Filed May 9, 1902. Serial No. 106,545. (No model.)



Claim.—1. In a sand-valve for filters, a body having a top plate, a side wall, and a port between said wall and plate, said plate being movable in part as a flap, whereby said port is adapted to be automatically reduced in area during the filtering process and which is automatically increased in area during the cleansing process.

2. In a sand-valve for filters, a body formed of a plate, a side wall and a port between said wall and plate, said plate being movable in part as a flap which is adapted to be automatically reduced in area during the filtering process, whereby the water is compelled to flow at a rapid rate through the port by reason of said decreased area, reducing the tendency of any foreign matter remaining therein, and said port being adapted to be automatically opened during the cleansing process by reason of the mobility of said plate of the valve thereby increasing the area to such an extent that the water passing therethrough is not materially retarded by friction, nor is it possible for any foreign substances to be held in said port.

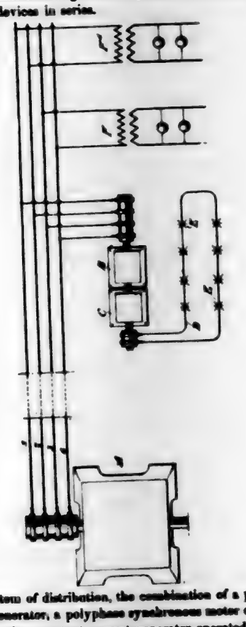
3. A sand-valve for a filter consisting of a plate and a side wall with a port between said wall and plate, said plate having a portion of the same severed forming a movable flap which is integral with said plate and adapted to regulate the area of said port.

707,334. SYSTEM OF DISTRIBUTION. JOHN F. KELLY, Pittsfield, Mass. Filed May 20, 1902. Serial No. 108,160. (No model.)

Claim.—1. In a system of distribution, the combination of a constant-potential alternating-current generator, an alternating-current motor connected in parallel thereto and a constant-current generator operated by said motor supplying translating devices in series.

2. In a system of distribution, the combination of a constant-potential generator, a synchronous motor supplied thereby, a constant-current generator operated by said motor and supplying translating devices in series.

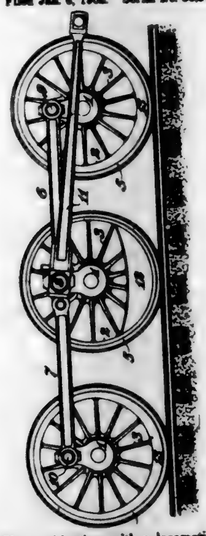
3. In a system of distribution, the combination of a constant-potential generator, a synchronous alternating-current motor supplied thereby, an alternating-constant-current generator operated by said motor and supplying translating devices in series.



4. In a system of distribution, the combination of a polyphase constant-potential generator, a polyphase synchronous motor operated thereby and an alternating-constant-current generator operated by said motor and supplying current to translating devices in series.

5. In a system of distribution by alternating currents, the combination of a constant-potential alternating-current generator, a synchronous alternating-current motor supplied thereby, an alternating-constant-current generator operated by said motor, and a series of arc-lamps supplied by said constant-current generator.

707,335. LOCOMOTIVE DRIVING-WHEEL. LOWELL H. KENYON, Allegheny, Pa. Filed Jan. 6, 1902. Serial No. 88,513. (No model.)



Claim.—1. The combination, with a locomotive driving-wheel, of an annular counterbalance having its center of gravity eccentric to that of the driving-wheel.

2. The combination, with a locomotive driving-wheel, of an annular counterbalance having its center of gravity eccentric to that of the driving-wheel and located on the side of the center thereof opposite to the crank-pin hub.

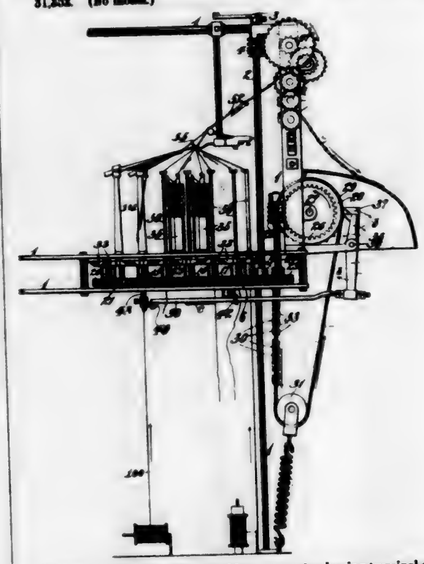
3. The combination, with a locomotive driving-wheel, of an annular counterbalance fixed upon the rim of the wheel and having a circumferential contour surface which is partly concentric and partly eccentric to that of the driving-wheel.

4. The combination, with a locomotive driving-wheel, of an annular counterbalance fixed upon the rim of the wheel and having a portion of its inner circumferential contour on the side of the center of the driving-wheel opposite to the crank-pin hub, eccentric to the driving-wheel.

5. The combination, with a locomotive driving-wheel, of an annular counterbalance fixed upon the rim of the wheel and having a greater portion of its weight located on the side of the center of the driving-wheel opposite to the crank-pin hub than on the other side thereof.

6. The combination, with a coupled locomotive driving-wheel, of an annular counterbalance having its center of gravity eccentric to that of the driving-wheel and which is made of such weight that the aggregate of its weight and those of the coupled wheel and connected revolving parts shall be substantially equal to that of the main driving-wheel, its counterbalance, and the connected revolving parts.

707,336. MACHINE FOR MAKING BRAIDS AND TRIMMINGS. JAKOB K. KIENZLE, Philadelphia, Pa., assignor to Hensel, Colladay Company, a Corporation of Pennsylvania. Filed Sept. 23, 1900. Serial No. 31,252. (No model.)



Claim.—1. In a braiding-machine, a race-ring having terminal elongated looped extensions leading therefrom, means for feeding a warp looping-thread through one of said extensions, means for changing the course of the racers or bobbin-holders to cause them to pass around the said extension-raceways to form an elongated loop in the warp-thread at the edge of the braid.

2. In a braiding-machine, a race-ring having terminal elongated looped extensions leading therefrom, means for feeding a warp looping-thread through one of said extensions, and means for changing the course of the racers or bobbin-holders to cause them to pass around the said extension-raceways to form an elongated loop in the warp-thread at the edge of the braid and means for automatically controlling the same.

3. In a braiding-machine, a race-ring having an elongated loop extension, a bobbin-holder in said race-ring, means for feeding a warp looping-thread through said extension, and means for preventing the bobbin-holder from traveling in the extended portion of said race-ring.

4. In a braiding-machine, a race-ring having an elongated looped extension, a bobbin-holder, means for feeding a warp looping-thread through one of said extensions, means for causing said holder to travel a certain course in said ring or through said extensions and means for automatically controlling the same.

5. In a braiding-machine, a race-ring having an elongated looped extension, switches therein, means for feeding a warp looping-thread through the extension and a jacquard for operating said switches.

6. In a braiding-machine, a race-ring having an elongated looped extension, a bobbin-holder, means for feeding a warp looping-thread through the extension and a switch in said race-ring for controlling the movement of the racers through said extension.

7. In a braiding-machine, a race-ring having an elongated looped extension, a bobbin-holder, means for feeding a warp looping-thread through the extension, a switch in said race-ring for controlling the movement of the racers through said extensions and means for controlling said switch.

8. In a braiding-machine, a race-ring having an elongated looped extension, bobbin-holders, means for operating said holders, means for feeding a warp looping-thread through the extension, a switch in said race-ring for controlling the movement of the racers through said extensions, and pattern-blocks for operating said switch.

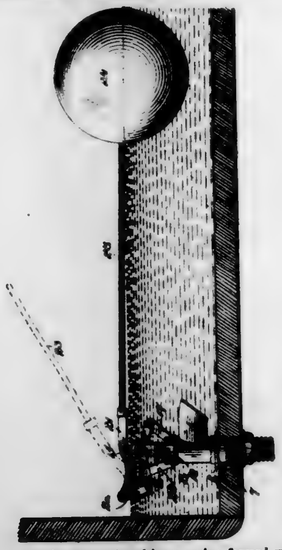
9. In a braiding-machine, a race-ring having an elongated looped extension, bobbin-holders, means for operating said holders, means for feeding a warp looping-thread through the extension, a switch for changing the course of said holders and controlling their movement through said extensions, rods suitably connected with said switches, and means for moving said rods, whereby said switches are opened and closed.

10. In a braiding-machine, a race-ring having an elongated looped extension, a bobbin-holder, means for operating the same, means for feeding a warp looping-thread through the extension, a switch in said race-ring for controlling the movement of the holder through said extensions, rods connected with said switches, arms secured to said rods, and means for operating said arms to open and close the switches.

11. In a braiding-machine, race-rings having an elongated looped extension, bobbin-holders, means for operating said holders, means for feeding a warp looping-thread through the extension, a switch in said rings for controlling the movement of the bobbin-holders through said extensions rods secured to said switches, arms secured to said rods, and a jacquard or bobbin-blocks adapted to operate said arms.

12. In a braiding-machine, a race-ring having an elongated looped extension, bobbin-holders therein, means for operating said holders, means for feeding a warp looping-thread through the extension, switches in said race-ring for controlling the movement of said holders through said extensions, means for operating said switches, bobbin-blocks, and means for operating the same.

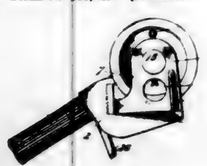
707,837. VALVE. JOHN H. KOCH, Scranton, Pa. Filed Aug. 5 1901. Serial No. 70,991. (No model.)



Claim.—1. A tank-valve, comprising a casing formed with an interior valve-seat, a plunger adapted to move longitudinally within said casing, a valve upon the inner end of said plunger designed to engage said valve-seat, the upper end of said plunger projecting beyond said casing and slotted transversely, a standard projecting from said casing, a lever fulcrumed to said standard and extending through the slot in said plunger, a relatively long slotted standard projecting from the opposite side of said casing to that of the first-mentioned standard and to a point above the parallel plane of the top of said plunger, the free end of said lever being passed through the slot of said slotted standard and guided thereby, a float-lever pivoted to the upper end of said slotted standard above said plunger-operating lever and extending parallel thereto transversely across the upper end of said plunger and means pivotally securing one end of said float-lever to the free end of said first-mentioned lever, projecting beyond the said slotted standard, the construction and arrangement being such that a lowering of the float-lever will raise the plunger, by means of its lever, the upward movement of said plunger being limited by contact with said float-lever, substantially as described.

2. In a valve for tanks, the combination of a suitable casing having a valve-seat formed therein, a cap for said casing provided with a vertical bore, a vertically-slidable plunger in said bore, adapted at its lower end to engage said valve-seat and provided at its upper end with a transverse slot, a relatively long radially-extending fulcrum-standard formed on the side of said cap, and extending above the horizontal plane of the top of said cap, a shorter standard formed on said cap opposite the relatively long standard, its top portion lying in the same horizontal plane as the slot in the plunger, a lever pivoted to the shorter standard and extending transversely through the slot of the plunger to a point beyond the extended standard, the portion of such lever in said slot being broadened to fit snugly therein, a float-lever pivoted intermediate its ends to the extended fulcrum-standard and lying transversely above the plunger, and a link connecting the short end of the float-lever with the free end of the plunger-lever.

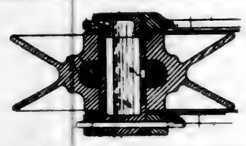
707,838. TROLLEY. PERRY E. LOREE, Dayton, Ohio. Filed Mar. 31, 1902. Serial No. 100,745. (No model.)



Claim.—1. In a trolley, the combination, with a pole provided with a head having rearwardly-extending lugs and rearwardly-extending flanges connected near their rear ends by a transverse piece or way, of a carriage pivotally mounted at its forward end between said lugs and provided at its rear end with an antifriction-wheel to bear upon the way and with a lug located between the flanges and extending under the way, said carriage having mounted thereon rearward of its pivot a trolley-wheel, substantially as described.

2. In a trolley, the combination, with a head having rearwardly-extending lugs and rearwardly-extending flanges, of a carriage provided with a trolley-wheel pivotally mounted at its forward end between the lugs and provided near its rear end on opposite sides with downwardly-diverging projections forming guards to prevent the engagement of the trolley-wire with the flanges, substantially as described.

707,839. TROLLEY-LUBRICATOR. PERRY E. LOREE, Dayton Ohio. Filed May 31, 1902. Serial No. 109,705. (No model.)

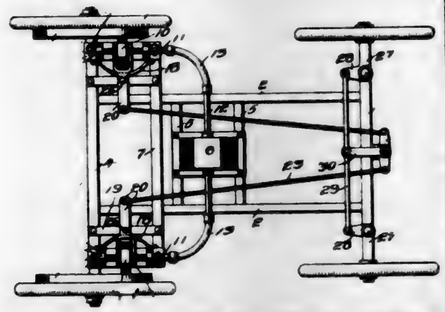


Claim.—1. A lubricator for trolley and other wheels, comprising a wheel provided with an internal circumferential groove having a filling of asbestos or other heat-resisting and flow-retarding material, and a non-rotating hollow spindle provided at one end with a removable closure for the introduction of a lubricant and having in its under side an aperture communicating with the groove of the trolley-wheel, substantially as described.

2. A lubricator for trolley and other wheels, comprising a wheel having an internal circumferential groove provided with a filling of asbestos or other heat-resisting and flow-retarding material, and a non-rotating hollow spindle provided with a removable closure at one end for the introduction of a lubricant, said spindle being provided with an aperture in its lower portion communicating with the groove of the trolley-wheel, a filling-aperture being formed to extend through said closure from its upper portion downward to the interior of the spindle, substantially as described.

3. In a lubricator for trolley and other wheels, the combination, with cheek-pieces having apertures, of a trolley-wheel having an internal circumferential groove provided with a filling of asbestos or other heat-resisting and flow-retarding material, a hollow spindle closed at one end, a key passing through one cheek-piece and the closed end of the spindle therein, a closure having a threaded connection with the other end of the spindle to close the open mouth thereof, said spindle being provided with an aperture in its under side communicating with the groove of the trolley-wheel, and said closure and the adjacent cheek-piece having an engaging projection and recess to insure the proper positioning of the spindle, substantially as described.

707,840. RUNNING-GEAR FOR AUTOMOBILES. ALBERT A MEDINA, East San Jose, Cal. Filed June 10, 1902. Serial No. 111,051. (No model.)



Claim.—1. In a device of the class described, the combination with rear wheels provided with friction-wheels, of friction-pinions engaging the same, means for driving the friction-pinions, steering mechanism, and means operated by the steering mechanism for moving the pinions simultaneously in opposite directions to arrange them at different distances from the centers of the friction-wheels, whereby the rear wheels are driven at different speeds, substantially as described.

2. In a device of the class described, the combination of a frame, rear wheels, friction-wheels connected with the rear wheels, friction-pinions engaging the friction-wheels, means for driving the friction-pinions, and means for automatically moving the friction-pinions simultaneously in opposite directions to arrange them at different distances from the centers of the friction-wheels when the vehicle is being turned, substantially as described.

3. In a device of the class described, the combination of a frame, rear wheels provided with friction-wheels, longitudinal shafts supported by the frame, a motor connected with the said shafts, friction-pinions slidably mounted on the shafts and engaging the friction-wheels, levers fulcrumed on the frame and arranged to engage the friction-pinions and means for simultaneously oscillating the levers in opposite directions when the vehicle is turned, substantially as described.

4. In a device of the class described, the combination of a frame, rear wheels, friction-wheels connected with the rear wheels, friction-pinions engaging the friction-wheels and capable of movement to carry them toward and from the centers of the friction-wheels, and means for arranging the friction-pinions at different distances from the centers of the friction-wheels when the vehicle is being turned, substantially as described.

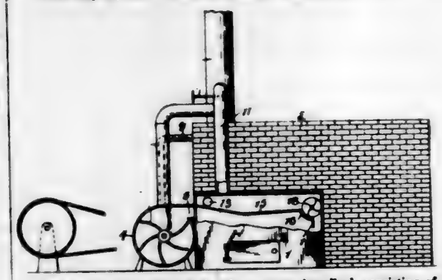
5. In a device of the class described, the combination of a frame, rear wheels provided with friction-wheels, plates slidably mounted on the frame, shafts journaled on the plates, friction-pinions slidably mounted on the shafts, springs engaging the plates and holding the pinions yieldably in engagement with the friction-wheels, a motor connected with the shafts and means for sliding the pinions on the shafts, substantially as described.

6. In a device of the class described, the combination of a frame, rear wheels provided with friction-wheels, plates slidably mounted on the frame, shafts carried by the plates, springs engaging the plates, a motor connected with the shafts, levers having forked or bifurcated portions receiving the pinions, and steering mechanism connected with the levers, substantially as described.

7. In a device of the class described, the combination of a frame, rear wheels provided with friction-wheels, slidable plates mounted on the frame and provided with bearings and arranged longitudinally, friction-pinions slidably mounted on the shafts, a motor having a transverse shaft provided with flexible sections connected with the longitudinal shafts, transverse levers fulcrumed on the frame and connected with the pinions, springs engaging the said plates and means for operating the levers, substantially as described.

8. In a device of the class described, the combination of a frame, rear wheels provided with friction-wheels, longitudinal shafts mounted on the frame, friction-pinions slidably mounted on the longitudinal shafts and engaging the friction-wheels, a motor having a transverse shaft provided with flexible sections connected with the longitudinal shaft, and means for sliding the pinions on the longitudinal shafts when the vehicle is turned, substantially as described.

707,841. SMOKE-CONSUMER. LEWIS R. MORGAN, Washington, D. C., assignor of one-half to Charles B. Cropley, Washington, D. C. Filed May 24, 1902. Serial No. 108,808. (No model.)



Claim.—1. A device of the character as described, consisting of a box, a concaved diaphragm located in said box and being secured at one end and at its longitudinal edges to the inner sides of the box, and at its other end terminating at a distance from the inner side of the box and leaving a space between the said end and the said inner side of the box, a fan journaled at the end of the diaphragm, and substantially filling the space between the end of the diaphragm and the inner side of the box, a means for introducing smoke below said diaphragm and a smoke-exit located above the said diaphragm.

2. A device of the character as described, consisting of a box, a diaphragm located in said box, said diaphragm having at its end a downwardly-curved portion, a revolving fan located above said curved portion, said box having a smoke-entrance located below the diaphragm and a smoke-exit located above the diaphragm.

3. A device of the character as described, consisting of a box, a diaphragm located in said box, said diaphragm having a downwardly-curved portion and a perpendicular end extending substantially parallel with the end of the box and at a distance from the said end, a revolving fan located above the downwardly-curved portion of the diaphragm, said box having a smoke-entrance located below the diaphragm and smoke-exit located above the diaphragm.

4. A device of the character as described, consisting of a box, a concaved diaphragm located in said box, said diaphragm having a downwardly-curved portion and a perpendicular end extending substantially parallel with the end of the box and at a distance from the same, a revolving fan located above the downwardly-curved portion of the diaphragm, said box having a smoke-entrance located below the diaphragm and a smoke-exit located above the diaphragm.

707,842. CAR-DOOR MECHANISM. EDGAR J. MÜLLER, Pittsburg, Pa., assignor to Pressed Steel Car Company, Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 16, 1902. Serial No. 103,175. (No model.)

Claim.—1. A car having a hinged downwardly-swinging door at its bottom, an incline upon the door, and a roller device arranged to act upon the incline to raise or lower the door; substantially as described.

2. A car having a series of downwardly-swinging transversely-extending doors, inclines upon the doors, rollers bearing upon the inclines, and connections for simultaneously moving the rollers to open or close the doors; substantially as described.

3. A car having a series of downwardly-swinging doors hinged to transverse pintles, inclines upon the doors, moving elements contacting with the inclines, and connections for moving said elements simultaneously to open or close the doors; substantially as described.

4. A car having a series of transverse downwardly-swinging doors with transversely-extending hinges, inclines on said doors, rollers bearing upon the inclines, swinging links carrying the rollers, and a connection for swinging the links simultaneously; substantially as described.

5. A car having downwardly-swinging doors in its bottom mounted

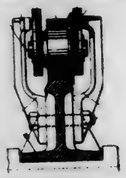
on transverse pintles, inclines on the bottom portions of the doors, depending links pivoted to the car and provided with rollers bearing upon the inclines, connections between the links on at least one side, and mechanism for swinging the links to open or close the doors; substantially as described.

6. A car having transverse downwardly-swinging doors hinged to transverse supporting shapes in a car-bottom and arranged end to end longitudinally of the car, said doors having inclines, rollers contacting with the inclines, and connections for simultaneously actuating the rollers to open or close the doors; substantially as described.

7. A car having a series of downwardly-swinging transverse doors extending longitudinally of the body, inclines on said doors, rollers contacting with the inclines, and a rock-shaft having connections arranged to move the rollers simultaneously to open or close the doors; substantially as described.

8. A car having a center sill, two series of doors arranged longitudinally between the center sill and the car sides, said doors swinging downwardly on transverse axes, depending links having rollers bearing upon inclines on the doors, and rock-shafts having connections with the links, each shaft being arranged to swing the links of one set of doors simultaneously; substantially as described.

707,848. LEER. ROBERT HAYSMITH and BENJAMIN F. REMER, Kittanning, Pa. Filed June 24, 1901. Serial No. 65,788. (No model.)



Claim.—1. A glass-leer having chain carriers having an upper and lower path of travel and provided with rollers, part of said rollers having flanges on one side, and others having flanges on the opposite side, and longitudinal supports for the rollers in the upper path of the chain; substantially as described.

2. A glass-leer having endless-chain carriers arranged with an upper and lower path of travel, side guides arranged to engage the links of the chain in the upper part of their travel, and mechanism for operating the chains; substantially as described.

3. A glass-leer having endless-chain carriers, mechanism for actuating the same, the links having flat upper edges forming a substantially continuous surface to receive the glass, supporting-rollers at each joint, the peripheries of the rollers being below the said edges of the links in the upper path of travel, and tracks upon which the rollers move in said upper path of travel; substantially as described.

4. A glass-leer having endless-chain carriers, mechanism for actuating the carriers, curved shoes over which the chains pass at the front end of their travel and mechanism for adjusting the shoes; substantially as described.

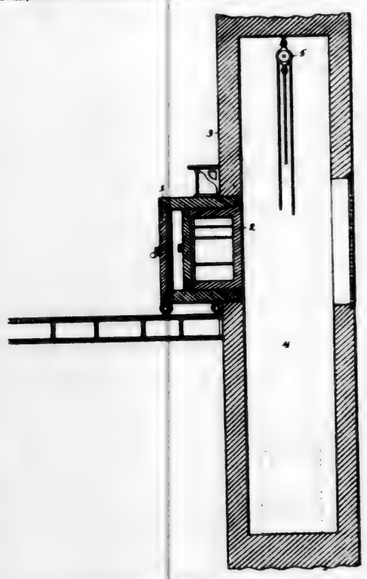
5. A glass-leer having endless-chain carriers arranged with an upper and lower path of travel, longitudinal rails supporting the chains in the upper part of their travel, and guides arranged to direct the pieces of glass into the intermediate spaces between the chains; substantially as described.

6. A glass-leer having endless-chain carriers, and heating-flues extending between the upper and lower paths of the chains; substantially as described.

7. A glass-leer having endless-chain carriers with an upper and lower path of travel and provided with rollers, and rails supporting the chains throughout the upper part of their travel, the succeeding rollers having flanges on alternate sides; substantially as described.

8. A glass-leer having longitudinal chain carriers, with an upper and lower path of travel provided with rollers, longitudinal rails upon which the rollers rest throughout the upper path of their travel, said rails having expansion-joints, and side guides arranged to engage the links of the chains and hold the chains against lateral movement; substantially as described.

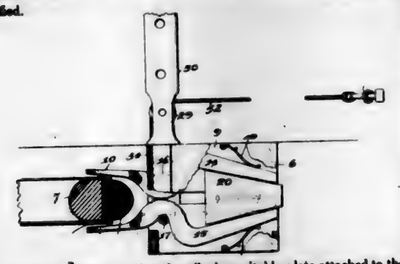
707,844. BURGLAR-PROOF SAFE. DAVID HEALE, Fort Calhoun, Nebr. Filed Nov. 19, 1901. Serial No. 82,931. (No model.)



Claim.—A safe of the class described composed of a casing having its rear side open; a second casing located within the first-mentioned casing and inserted through the rear side, and a pit located to the rear of the safe for receiving the second-mentioned casing when an attempt has been made to explode the safe, substantially as specified.

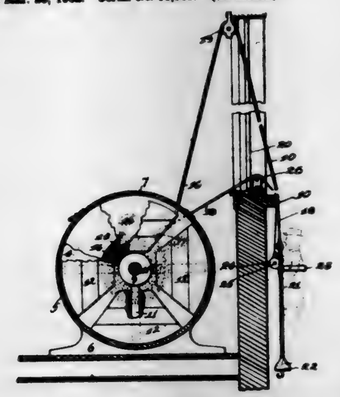
707,845. COMBINATION BRAKE, FENDER, AND STEP. DAVID HEALE, Fort Calhoun, Nebr. Filed Feb. 10, 1902. Serial No. 93,817. (No model.)

Claim.—1. In a device of the class described, a suitable plate attached to the bed of the carriage in a horizontal position, and in position convenient to be used as a step for entering or leaving the carriage; a second plate mounted below the first plate by suitable framework to form a chamber between the two plates; two jaws pivotally mounted side by side in a horizontal position within said chamber, the rear ends of said jaws being adapted to grip the side face of the metal tire of the carriage-wheel; a wedge mounted to slide between the forward ends of the jaws as required to open and close the jaws, there being a spring-recess formed in the lower face of said wedge; a coil-spring mounted in said recess one end of the coil-spring engaging the wedge, and the other end of the coil-spring connected to the frame to press the wedge backwardly and allow the jaws to open to release the tire; springs mounted in the frame and engaging the forward ends of the jaws; the tension of said springs being exerted to open said jaws and release the tire; a post extending downwardly from said wedge through the frame; a guide-pulley mounted in the frame below the forward end of the wedge; a second guide-pulley mounted in the lower part of the frame below the rear end of the wedge; a third guide-pulley mounted under the bed of the carriage; a cord attached to said post, extending around said guide-pulleys; and a lever at the forward end of said cord for operating the brake, substantially as specified.



2. In a device of the class described, a suitable plate attached to the bed of the carriage in a horizontal position, and in position convenient to be used as a step for entering or leaving the carriage; a second plate mounted below the first plate by suitable framework to form a chamber between the two plates; two jaws pivotally mounted side by side in a horizontal position within said chamber, the rear ends of said jaws being adapted to grip the side face of the metal tire of the carriage-wheel; a wedge mounted to slide between the forward ends of the jaws as required to open and close the jaws, there being a spring-recess formed in the lower face of said wedge; a coil-spring mounted in said recess one end of the coil-spring engaging the wedge, and the other end of the coil-spring connected to the frame to press the wedge backwardly and allow the jaws to open to release the tire; springs mounted in the frame and engaging the forward ends of the jaws, the tension of said springs being exerted to open said jaws and release the tire; a post extending downwardly from said wedge through the frame; a guide-pulley mounted in the frame below the forward end of the wedge; a second guide-pulley mounted in the lower part of the frame below the rear end of the wedge; a third guide-pulley mounted under the bed of the carriage; a cord attached to said post, extending around said guide-pulleys; a lever at the forward end of said cord for operating the brake; and a fender extending upwardly from said step-plate, substantially as specified.

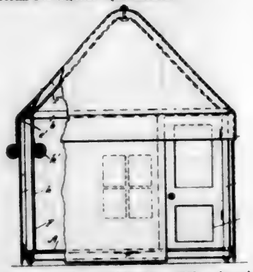
707,846. FIRE-ESCAPE. DAVID HEALE, Fort Calhoun, Nebr. Filed Mar. 25, 1902. Serial No. 99,903. (No model.)



Claim.—1. A fire-escape comprising a suitable frame; a carrying-shaft mounted in the frame; a carrying-rope attached to the carrying-shaft and adapted to be wound thereon; a carrying-shaft speed-governor attached to the carrying-shaft; a brake connected to the shaft; a brake-rope connected to the brake; a carrying-frame attached to the opposite end of the carrying-rope from the carrying-shaft; a brake-shaft mounted in said carrying-frame, said brake-rope being attached to and wound upon said brake-shaft; and a brake-rope speed-governor upon said brake-shaft, substantially as specified.

2. In a fire-escape, the base 6; the casing 5 mounted upon the base; the end pieces 4 closing the casing; the door 7 providing access to one end of the casing; the slot 8 providing access to the other end of the casing; the carrying-shaft 9 mounted in the bearings in the end pieces 4; the carrying-rope 10 wound upon the shaft and passing outwardly through the slot 8; the arms 11 extending radially from the shaft 9, the centrifugal weights 12 slidingly mounted upon said arms to engage the inner face of the casing; the brake-wheel 14 fixed upon the shaft 9; the brake-band 15 engaging the brake-wheel; the brake-rope 18 attached to the brake-band; the carrying-frame 21 attached to the lower end of the carrying-rope; a brake-shaft mounted in the carrying-frame upon which the brake-rope is wound; and a governor controlling the brake-shaft, substantially as specified.

707,847. TENT. JOHN P. NELSON, Waltham, Mass. Filed Dec. 5, 1901. Serial No. 84,786. (No model.)

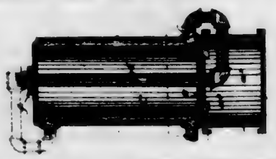


Claim.—In a tent, the combination, with a knockdown frame, of an outer covering of textile material extending over the exterior of the top and sides of the frame and provided with window-openings, an inner covering of textile material extending over the interior of the top and sides of the frame and provided with window-openings opposite the aforesaid window-openings, air-spaces being formed of the width of the elements of the said frame between the two said coverings, and curtains of textile material for closing the said window-openings arranged inside the inner covering and outside the outer covering respectively, substantially as set forth.

707,848. BOTTLE-STOPPER. ALONZO C. PACKER, Pittsburg, Pa., assignor of two-thirds to John A. Young and William R. Patterson, Pittsburg, Pa. Filed July 9, 1900. Serial No. 22,892. (No model.)

Claim.—In a bottle, a stopper, a cap, a recess in the lower end of said cap, an elastic ball, said ball compressed into and so secured in said recess that it can be rotated in any direction of its axis to present new bearing-surfaces when sealed and a bail extending from said cap to said bottle.

707,849. WATER-HEATER. THOMAS L. PHILLIPS, Aurora, Ill. Filed Mar. 3, 1902. Serial No. 96,530. (No model.)



Claim.—1. A water-heater comprising a vertical, narrow fire-box, a grate at the bottom of the fire-box, and a water-conducting pipe extending from the center of the grate throughout the entire length of the fire-box and in the center thereof, substantially as set forth.

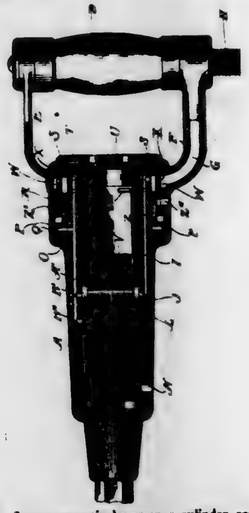
2. A water-heater comprising a long, narrow, vertical fire-box, a grate at the bottom of said box, and a water-conducting pipe extending upwardly through said grate, and throughout the entire length of the fire-box, as set forth.

3. A water-heater comprising a fire-box, a water-chamber surrounding said box, a pipe communicating with said chamber, passing through the grate from below, and extending throughout the entire length of said fire-box and in the center thereof, as set forth.

4. In a water-heater, a vertical fire-box narrow in cross-section and adapted to be entirely filled with fuel, a water chamber or jacket surrounding the fire-box, a water-pipe communicating with said chamber and passing throughout the entire length of the fire-box and in the center thereof, said pipe and chamber communicating with a system of water-pipes and radiators substantially as set forth.

5. In a water-heater, a vertical fire-box, narrow in cross-section and provided at the top with means for introducing fuel, at the bottom with a grate and ash-pan, and without openings in its sides; a water-chamber surrounding the fire-box, and water-conducting pipe communicating with said chamber, passing under said grate and up through the center thereof, and extending throughout the length of the fire-box, for the purpose described.

707,850. PNEUMATIC HAMMER. CHARLES K. PICKLER, St. Louis, Mo., assignor, by mesne assignments, to Chicago Pneumatic Tool Company, a Corporation of New Jersey. Filed Jan. 27, 1900. Serial No. 2,982. (No model.)



Claim.—1. In a pneumatic hammer, a cylinder containing a live-air passage opening into the piston-chamber by a suitable port, a piston reciprocating in said chamber and provided with a passage whose rear end is brought into communication with the live-air port at the forward end of the stroke of the piston and serves to admit the motive fluid, through the piston, to the front end of the piston-chamber, to drive the piston rearward, in combination with an independent valve located in a chamber separate from the piston-chamber and operating to control the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

2. In a pneumatic hammer, a cylinder containing a live-air passage opening into the piston-chamber by a suitable port, a piston reciprocating in said chamber and provided with a circumferential groove adapted to register with said port as the piston approaches the forward end of its stroke, and with a central longitudinal passage communicating at its rear end by a lateral passage with said groove and extending forwardly through the piston, and serving to convey the motive fluid through the piston to the front end of the piston-chamber, to drive the piston rearward, in combination with an independent valve operating to control the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

3. In a pneumatic hammer, a cylinder containing a live-air passage opening into the piston-chamber by a port about midway of the length of said chamber, a piston reciprocating in said chamber and provided near its rear end with a circumferential groove adapted to register with said port at the end of the forward stroke of the piston, and with a transverse passage communicating with said groove and with a longitudinal passage extending forwardly through the piston from said transverse passage, for the purpose of conveying the motive fluid through the piston to the front end of the piston-chamber, in combination with an independent valve located in a chamber separate from the piston-chamber for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

4. In a pneumatic hammer, a cylinder containing a live-air passage communicating at its rear end with the source of supply and opening at its forward end into the piston-chamber by a port about midway of the length of said chamber, a piston reciprocating in said chamber and provided near its rear end with a circumferential groove adapted to register with said live-air port at the end of the forward stroke of the piston, and with a passage communicating at its rear end with said groove and extending forwardly through the piston, for conveying the motive fluid through the piston to the front end of the piston-chamber, in combination with an independent differential valve for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, said valve being shifted in one direction by a constant pressure upon its smaller area, and in the opposite direction by motive fluid admitted to its larger area through a passage extending through the cylinder-wall and opening into the piston-chamber by a port which is placed in communication with the live-air port by the groove in the piston at the end of the forward stroke of the latter, substantially as described.

5. In a pneumatic hammer, a cylinder containing a piston-chamber having a uniform diameter throughout its length, a piston of corresponding diameter reciprocating in said chamber and operating as its own valve to control the inlet of the motive fluid to the front end of the piston-chamber, in combination with an independent valve located in a chamber separate from the piston-chamber for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

6. In a pneumatic hammer, a cylinder containing a piston-chamber of uniform diameter throughout its length, a piston of corresponding diameter reciprocating in said chamber, and provided with a circumferential groove and a central longitudinal passage cooperating with a live-air passage and port in the cylinder-wall to cause the piston to operate as its own valve for controlling the inlet of the motive fluid at the front end of the piston-chamber, in combination with an independent valve for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

7. In a pneumatic hammer, a cylinder containing a piston-chamber of uniform diameter throughout its length, a piston of corresponding diameter reciprocating therein and operating as its own valve to control the inlet of the motive fluid to the front end of the piston-chamber, in combination with an independent annular valve reciprocating in the line of movement of the piston in a chamber separate from the piston-chamber for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, substantially as described.

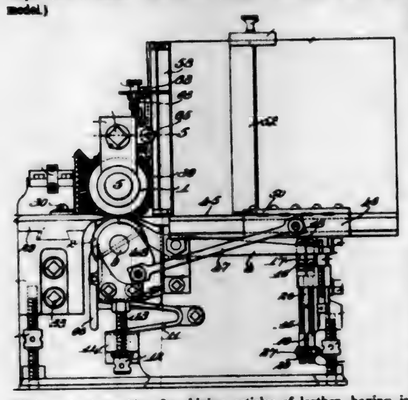
8. In a pneumatic hammer, a cylinder containing a piston-chamber of uniform diameter throughout its length, a piston of corresponding diameter reciprocating therein and operating as its own valve to control the inlet of the motive fluid to the front end of the piston-chamber, in combination, with a differential annular valve reciprocating in the line of movement of the piston for controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, said valve being shifted in one direction by constant pressure of the motive fluid upon its smaller area, and in the opposite direction by motive fluid intermittently admitted to its larger pressure area through a passage in the cylinder-wall placed in communication with the live-air supply by a groove in the piston at the end of the forward stroke of the latter and opened to the exhaust at the end of the rearward stroke thereof, substantially as described.

9. In a pneumatic hammer, the combination of the cylinder A containing the live-air passage I opening into the piston-chamber by the port J, the piston B provided with the passage L M and groove K coöperating with the port J, and the differential valve P controlled by the piston through the passage A′ connecting the valve-chamber with the piston-chamber, substantially as described.

10. In a pneumatic hammer, the cylinder A provided with the live-air passage I and port J, passage A′ communicating at its rear end with the valve-chamber and opening at its forward end into the piston-chamber by the two ports B′ B″, and an exhaust-port N for the front end of the piston-chamber, in combination with the piston B provided with the passage L M and with the groove K coöperating with the ports J and B′, and the differential valve P controlled by the piston through the medium of the passage A′, substantially as described.

11. In a pneumatic hammer, the combination of the cylinder having the tool-receiving bore at its forward end, to receive the shank of the working tool, and the intermediate disk of non-resilient material located wholly within and fitting the forward end of the piston-chamber and closing said opening, substantially as described.

707,851. LEATHER-SKIVING MACHINE. JOHN W. POOLE, Lynn, Mass., assignor to the Poole Skiving Company, Kittery, Me., a Corporation of Maine. Filed Dec. 4, 1901. Serial No. 84,689. (No model.)



Claim.—1. A machine for skiving articles of leather, having, in combination, a die-roller, a series of pressure-levers, springs acting upon the levers, a stop-bar for limiting the movement of the levers under the force of the springs, a bar to which the springs are secured, and means for simultaneously adjusting said bars, substantially as described.

2. A machine for skiving articles of leather, having, in combination, a die-roller, a series of pressure-levers, springs acting upon the levers, an adjustable stop-bar for limiting the movement of the levers under the force of the springs, and a bar to which the springs are secured movable with the stop-bar, substantially as described.

3. A machine for skiving articles of leather, having, in combination, a die-roller, a series of pressure-levers, springs acting upon the levers, a stop-bar for limiting the movement of the levers under the force of the springs, a bar to which the springs are secured, and an adjustable support common to both bars, substantially as described.

4. A machine for skiving articles of leather, having, in combination, a die-roller, a series of pressure-levers, a spring acting upon each lever, an adjustable stop-bar for limiting the movement of the levers under the force of the springs, a bar to which the springs are secured movable with the stop-bar, and means for adjusting the tension of the springs separately, substantially as described.

5. A machine for skiving articles of leather, having, in combination, a die-roller, a pressure device, a support adjustable perpendicularly to the plane of feed, a knife-carrier mounted in guideways on said support to move transversely to the direction of feed, a skiving-knife secured to said carrier, a lever, a link connecting the lever and carrier, and means for oscillating the lever, substantially as described.

6. A machine for skiving articles of leather, having, in combination, a die-roller, a pressure device, a skiving-knife adjustable perpendicularly to the plane of feed, and means for vibrating the knife transversely to the direction of feed, substantially as described.

7. A machine for skiving articles of leather, having, in combination, a die-roller, a die-roller shaft, a pressure device, a knife-carrier mounted to move transversely to the direction of feed, a skiving-knife secured thereto, a lever, a link connecting the lever and knife-carrier, a shaft and intermediate connections for oscillating the lever and gearing connecting said shaft and the die-roller shaft, substantially as described.

8. A leather-skiving machine, having, in combination, a die-roller, a pressure device, a feed-table, mechanism for feeding blanks to the die-roller and pressure device, and a hopper comprising a side wall and a front wall, said front wall being pivotally mounted to swing toward and from the side wall, substantially as described.

9. A leather-skiving machine, having, in combination, a die-roller, a pressure device, a feed-table, mechanism for feeding blanks to the die-roller and pressure device, a hopper comprising a side wall and a front wall, said front wall being pivotally mounted to swing toward and from the side wall, and means for adjusting the front wall bodily toward and from the feed-table, substantially as described.

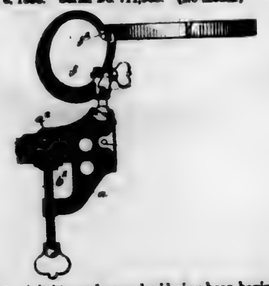
10. A leather-skiving machine, having, in combination, a die-roller, a pressure device, a feed-table, mechanism for feeding blanks to the die-roller and pressure device, a hopper comprising a side wall and a front wall, said front wall being pivotally mounted to swing toward and from the side wall, and means for adjusting the front wall toward and from the side wall, substantially as described.

11. A leather-skiving machine, having, in combination, a die-roller, a pressure device, a feed-table, mechanism for feeding blanks to the die-roller and pressure device, a hopper comprising a side wall and a front wall, said front wall being pivotally mounted to swing toward and from the side wall, and means for adjusting the front wall toward and from the side wall, substantially as described.

707,852. METHOD OF FORMING JOINTS FOR INTERJECTING WIRES OR RODS. JOHN C. PORT and WILLIS J. PORT, Piano, Ill. Filed Feb. 8, 1901. Serial No. 46,548. (No model.)

Claim.—The herein-described method of casting joints and immediately using the flask for further casting, which consists in disposing the elements to be joined within a flask inclosing a removable chill, flowing molten metal within the chill and around the said elements, removing the flask from the chill and then supplying it with another chill and repeating the operation.

707,858. EMBROIDERY FRAME AND HOLDER. JOHN H. POST, Hartford, Conn., assignor, by mesne assignments, to the Leader Manufacturing Company, Hartford, Conn., a Corporation of Connecticut. Filed Apr. 6, 1899. Serial No. 711,908. (No model.)



Claim.—1. A holder and an embroidering-hoop having as elements an interengaging groove and flange, one of said elements being located on and extending circumferentially of the hoop, whereby a rotary movement of the hoop on its support is permitted.

2. A holder for embroidery-hoops or the like including branching arms, and a hoop, said hoop and arms having as elements an interengaging groove and flange, one of said elements being located on and extending circumferentially of the hoop, whereby a rotary movement of the hoop on its support is permitted.

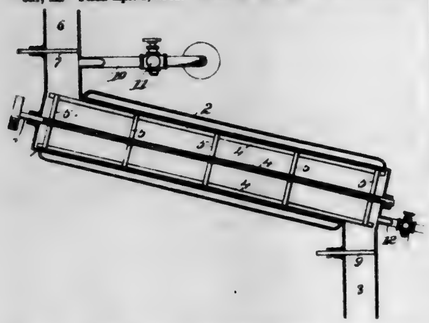
3. An embroidering-hoop holder including branching arms, and an embroidering-hoop adapted to be adjustably secured to said holder, one of said parts having a groove and the other a projection each adapted to engage the other whereby the hoop is frictionally held by and adjustable in a circumferential direction on said arms.

4. An embroidering-hoop holder having branching arms, recesses formed in the outer face of said arms, and a hoop having a rib extending circumferentially about the hoop and adapted to engage said recesses.

5. In an embroidering-hoop holder, in combination, a bracket having means of attachment to a fixed object, a holder adjustably secured to the bracket, and an embroidering-hoop, said hoop and holder having as elements an interengaging flange and groove, one of said elements being located on and extending circumferentially of the hoop, whereby a rotary movement of the hoop on its support is permitted.

6. In an embroidering-hoop and holder, in combination, a bracket having means of attachment to a fixed object, a holder adjustably secured to the bracket and having branching arms, and an embroidering-hoop supported by the holder, said holder and hoop having as elements an interengaging flange and groove, one of said elements being located on and extending circumferentially of the hoop, whereby a rotary movement of the hoop on its support is permitted.

707,854. PROCESS OF DEODORIZING. FRANK M. PRATT, Decatur, Ill. Filed Apr. 5, 1902. Serial No. 101,583. (No specimens.)



Claim.—1. The process of deodorizing which consists in supplying a batch of the material to be treated to an externally-heated chamber, holding the material in the chamber until the temperature of the material is high enough to avoid condensation of steam, and then passing live steam through the material; the material being continuously stirred and external heat being continuously applied to the chamber during the several steps of the process.

2. The process of deodorizing which consists in supplying the material to be treated to an externally-heated chamber, stirring the material in the heated chamber, closing the chamber against admission of air and passing live steam through the material in the chamber while continuing the stirring and the application of external heat.

707,855. CONVEYING-BELT. JOHN J. RIDGWAY, Rosebank, N. Y. Filed Dec. 7, 1901. Serial No. 85,069. (No model.)

Claim.—1. A conveyer-belt adapted to be bent along lines parallel to its length to form a conveying-trough and consisting of a fabric core and an elastic covering thickened along the lines of flexure between the center and the edge portions of the belt, the center and edge portions of the belt-covering being thinner than such thickened portions.

2. A conveyer-belt adapted to be bent along lines parallel to its length to form a conveying-trough and consisting of a fabric core and a rubber covering thickened on both sides of the belt along the lines of flexure between the center and the edge portions of the belt.

3. A belt having a fabric core and a rubber covering with thickened portions on both sides of the belt along lines parallel to its length between the center and the edge portions of the belt, the fabric core being correspondingly thinner at such portions and the belt being of substantially even thickness throughout.

4. A conveyer-belt having a fabric core, and a rubber cover with thickened portions along lines parallel to its length, on both sides of the belt, and between the center and the edge portions of the belt.

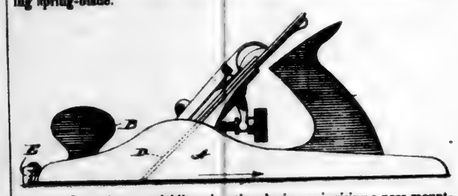
5. A conveyer-belt having a fabric core, and a rubber cover with thickened portions along lines parallel to its length, on both sides of the belt, in combination with means for supporting different portions of said belt so as to bend same reversely and move same in opposite directions.

707,856. PLANE-LIFT. CHARLES H. RISCHER and HENRY S. WALTER, New Britain, Conn., assignors to Stanley Rule and Level Company, New Britain, Conn., a Corporation of Connecticut. Filed Apr. 26, 1902. Serial No. 104,806. (No model.)

Claim.—1. In a plane, an elevating device projecting beyond the front end of the plane and means of connection between said elevating device and a portion of the plane, and means to normally cause said elevating device to project below the sole of the plane.

2. In a plane, an elevating device projecting beyond the end of the plane and means of connection between said elevating device and a portion of the plane, and a spring to normally cause said elevating device to project below the sole of the plane.

3. A plane having a front and a rear handle, an elevating device secured to the plane by the front handle said connection including a yielding spring-blade.



4. In a plane, a yielding elevating device comprising a nose mounted on the plane in front of the forward end thereof, and a spring for normally causing said elevating device to project below the sole of the plane, the operative edge of said elevating device being rounded.

5. An elevating device for a plane comprising a carrier, blades projecting forwardly therefrom and carrying a nose portion projecting downward therefrom, substantially as described.

6. An elevating device for a plane comprising a carrier portion G, a downwardly-projecting nose portion E, and means for connecting said carrier and said nose portion.

7. An elevating device for a plane comprising a downwardly-projecting nose portion, adapted to project beyond the end of a plane, a spring-blade attached thereto and means carried by said blade portion whereby said elevating device may be attached to a plane on top of its sole portion.

707,857. POWER-SHAFT COUPLING. OLE RUDD, West Duluth, Minn. Filed Mar. 17, 1902. Serial No. 98,613. (No model.)

Claim.—1. In a shaft-coupling the combination of coöperating collars respectively secured to the opposing ends of opposite sections of a shaft, said collars each being provided with longitudinally-projecting dovetail tenons having arcs of less length than the respectively intervening spaces, the tenons on one collar being adapted to project into the recessed spaces formed by and between the tenons of the opposite collar and to engage the tenons of said opposite collar, a sufficient space being left between the edges of said tenons for the introduction of securing means, and securing means within said space, substantially as described.

2. In a shaft-coupling, the combination of coöperating collars respectively secured to the opposing ends of opposite sections of a shaft, said collars being provided with longitudinally-projecting radially-disposed dovetail tenons, having arcs of less length than the respectively intervening recessed spaces, the tenons of one collar being adapted to project into recessed spaces formed by and between the tenons of the opposite collar and to engage the tenons thereof in interlocked position, means being interposed between one set of contiguous edges of said tenons for securing the same together, substantially as described.

3. A shaft-coupling, comprising coöperating collars adapted to receive a shaft, each collar being provided with longitudinally-projecting radially-disposed dovetailed tenons of a less width than the spaces between the said tenons on each collar, the tenons of one collar being adapted to project into the recessed spaces formed between the tenons of the opposite collar, but not entirely filling the same, and means for filling the remainder of said spaces not occupied by said tenons for securing the said tenons of the opposing collars in interlocked position, substantially as described.

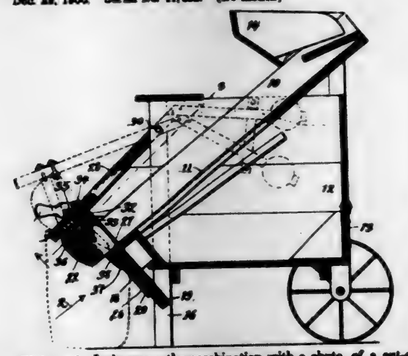
4. A shaft-coupling comprising coöperating collars adapted to receive a shaft, each collar being provided with longitudinally-projecting radially-disposed dovetail tenons having arcs of less length than the spaces intervening between the respective tenons of the opposite collar, the tenons of one collar being adapted to project into recessed spaces formed between the tenons of the opposite collar and to engage said tenons of said opposite collar in interlocked position; wedges between the edges of said tenons for securing the tenons of said opposite collars in interlocked position, substantially as described.

5. A shaft-coupling comprising coöperating collars adapted to receive a shaft, each collar being provided with longitudinally-projecting radially-disposed dovetail tenons having arcs of less length than the spaces intervening between the respective tenons of the opposite collar, the tenons of one collar being adapted to project into recessed spaces formed between the tenons of the opposite collar and to engage said tenons of said opposite collar in interlocked position; radially-disposed wedges adapted to fill the remaining space between adjoining interlocked tenons and to secure the same in interlocked position, substantially as described.

6. A shaft-coupling comprising coöperating collars adapted to receive a shaft, each collar being provided with longitudinally-projecting radially-disposed dovetail tenons of less width, respectively than the spaces intervening between the respective tenons of the opposite collar, the tenons of one collar being beveled laterally at one upper corner, the tenons of one collar being adapted to engage and interlock with the tenons of the opposite collar; and key-wedges for securing said tenons in interlocked position each formed with a disengaging lip at its upper end, substantially as described.

7. A shaft-coupling comprising coöperating collars secured to the ends of the shaft-sections which are to be coupled, the said collars having upon their meeting faces tenons formed with dovetailed edged faces, key-wedges having shanks formed with beveled faces corresponding with the beveled faces of the said tenons, the said wedges fitting between the edges of the tenons of the coöperating collars for completing a dovetail joint between said collars, substantially as described.

707,858. COAL-BAGGER. HIRAM B. SACKETT, Chicago, Ill. Filed Dec. 29, 1900. Serial No. 41,422. (No model.)



Claim.—1. In baggers, the combination with a chute, of a cut-off gate therefor, a handle connected to said gate to positively shift the same both to its open and closed positions and a bodily-movable spreader for the bag connected to said handle to simultaneously shift therewith and with said gate, said spreader being arranged to move inwardly as the gate is opened to hold the inner edge of the bag close to the open end of the chute and to move outwardly to release the bag as said gate is closed.

2. In baggers, the combination with an inclined chute, of a sliding cut-off gate therefor, a swinging operating-lever and handle to which said cut-off is pivotally connected and a spreader for the bag rigidly connected to said operating-lever.

3. In baggers, the combination with an inclined chute, of a sliding cut-off gate therefor having a discharge-opening and spout, guides for said gate, a swinging operating-lever above said chute to which said gate is pivotally connected and a bag-spreader rigidly connected to said lever and arranged to embrace said spout.

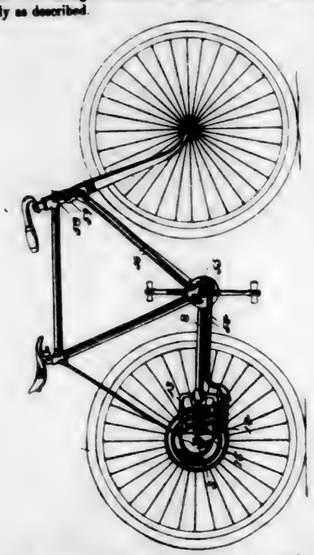
707,859. CHANGEABLE GEAR FOR BICYCLES. PETER J. SCHARBACH, Po Ell, Wash. Filed Jan. 3, 1902. Serial No. 88,346. (No model.)

Claim.—1. The combination in a changeable gear for cycles and with the rear wheel thereof having a gear-disk provided with a plurality of gears thereon, a driving-shaft, a plurality of gears supported on said shaft and meshing with the gears carried by the rear wheel, gear-clutches, clutch-levers, and triggers for operating said clutch-levers, said triggers arranged to be thrown into inactive position, substantially as described.

2. The combination in a changeable gear for cycles and with the rear wheel thereof having a plurality of gears, of a drive-shaft, a plurality of gears supported by said shaft and meshing with the gears carried by the said rear wheel, clutches coacting with said gears, clutch-levers, a series of triggers coacting with said clutch-levers and means for operating said triggers, substantially as described.

3. The combination in a changeable gear for cycles and with the rear wheel thereof having a plurality of gears, of a drive-shaft, having a plurality of gears meshing with the gears carried by the rear wheel, a series of clutches and clutch-levers for the same, a plurality of triggers coacting with said clutch-levers, and two levers and intermediate connections for operating said triggers, one of said levers arranged to throw said triggers into inactive positions, substantially as described.

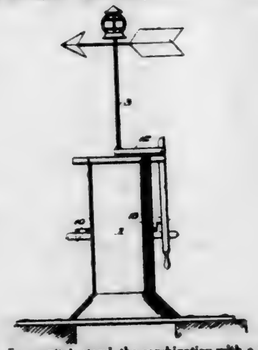
4. The combination in a changeable gear for cycles and with the rear wheel thereof having a plurality of gears thereon, of a drive-shaft carrying a plurality of gears meshing with the aforesaid gears, a plurality of clutches and clutch-levers coacting with said gears, a bar slidingly arranged with relation to said clutch-levers, a plurality of triggers supported by said bar, and two levers and intermediate connections for operating said bar and triggers, one of said levers arranged to slide said bar, and the other lever arranged to move said triggers into inactive position, substantially as described.



5. The combination in a changeable gear for cycles and with the rear wheel thereof having a plurality of gears thereon, of a drive-shaft carrying a plurality of gears and clutches, a plurality of clutch-levers, a plurality of triggers for operating said clutches, a lever arranged to throw said triggers into inactive position, and a spring arranged to hold said lever in position, substantially as described.

6. The combination in a changeable gear for cycles and with the rear wheel thereof carrying a plurality of gears, a drive-shaft carrying a plurality of gears and clutches for the same, a plurality of suitably-supported clutch-levers, a bar suitably supported near such clutch-levers, a second bar slidingly supported by said first bar and carrying a plurality of triggers, two levers, and intermediate connections between said levers and the sliding bar and the triggers, substantially as described.

707,860. SWITCH-STAND. JOHN J. SCHRAM, Toledo, Ohio, assignor of one-half to Thomas L. Gourley, Toledo, Ohio. Filed Mar. 20, 1902. Serial No. 98,134. (No model.)



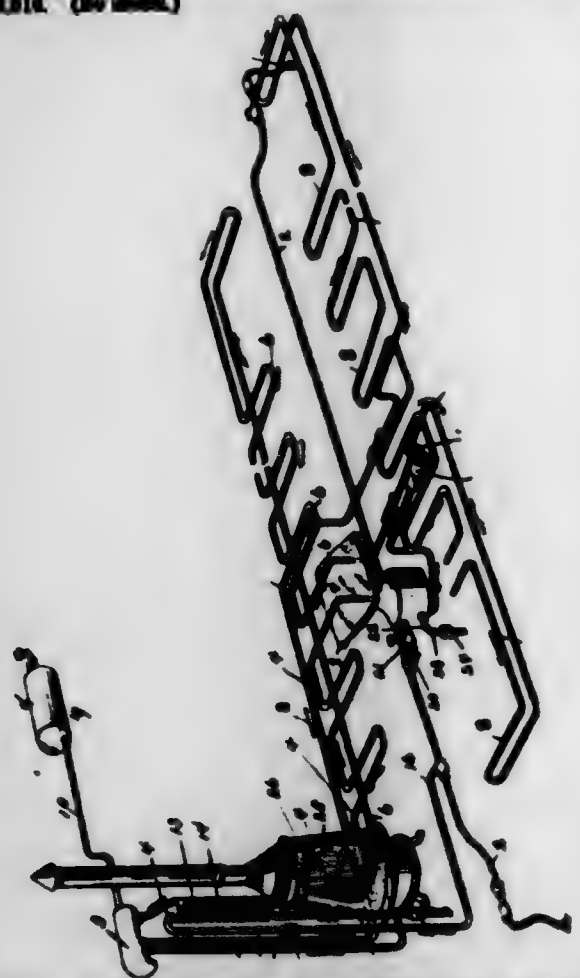
Claim.—1. In a switch-stand, the combination with a frame or casing, of a switching-lever, a device on the frame or casing adapted for engagement and locking with said lever when the latter is in a predeter-

mined position in relation thereto, and a movable abutment adapted to be positioned in advance of the lever to arrest the movement of said lever and prevent it from assuming said predetermined position.

2. In a switch-stand, the combination with a frame or casing, of a switching-lever, a projecting member on the casing, provided with a socket, a lock on the lever adapted to engage said socket, and a movable latch on the casing or frame which is adapted to be fitted into the socket and to constitute an abutment to prevent the lever from assuming a position where its lock will engage the socket.

3. In a switch-stand, the combination with a frame or casing, of a switching-lever, a projecting member on the casing, provided with a socket, a lock on the lever adapted to engage said socket, a pivoted latch having a head adapted to be made to fit into the socket and to constitute an abutment for the lever to prevent the latter from assuming a position where its lock will engage the socket.

707,861. RAILWAY-CAR-HEATING APPARATUS. John O. C. Searle, Chicago, Ill.; Julia R. Searle executrix of said John O. C. Searle, deceased. Filed Mar. 22, 1898. Renewed Aug. 26, 1901. Serial No. 626,514. (No model.)



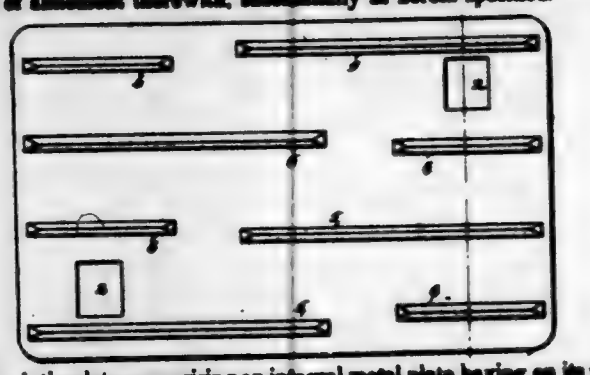
Claim.—1. The combination, of a circulatory system that includes a heat-radiating portion and has an ascending pipe on one side thereof and a descending pipe on the other side thereof, a heater in the ascending pipe or upon one side thereof, and a second heater located below the first-named heater and at substantially the lowest point of the circuit.

2. The combination, of a circulatory system that includes a heat-radiating portion and has an ascending pipe on one side thereof, a descending pipe on the other side thereof and an expansion-chamber located above said pipes and having communication therewith, an emergency-heater having a combustion-chamber inclosing a portion of the ascending pipe of said system, a primary heater located at substantially the lowest point of the circuit, and means for transferring heat derived from a main source of heat-supply into operative contact with the circulating liquid in said last-named heater.

3. In combination, a water-circulating system having a radiating portion in the descending pipe or upon one side thereof, a heater in the ascending pipe or upon the other side thereof, and a second heater located below the first-named heater and at substantially the lowest point of the circuit.

707,862. TIE-PLATE. Charles S. Shallenberger, Milwaukee, Wis., assignor of one-half to Edward S. Marshall, St. Louis, Mo. Filed Nov. 14, 1901. Serial No. 82,212. (No model.)

Claim.—1. The improved metallic tie-plate comprising the plate 1 having spike-openings 2, a step 3 located on the upper side of said plate, a series of longitudinal projections 5 formed integral with the under side of said plate and extending more than half the length thereof, and a series of shorter projections 6 arranged at one end of the said projections 5 but out of alinement therewith, substantially as herein specified.



2. A tie-plate, comprising an integral metal plate having on its under surface two series of thin, parallel ribs, one series extending from near one edge to beyond the middle transverse line of the plate, and the other series extending from near the opposite edge of the plate to beyond the middle transverse line of the plate, the two series overlapping each other at their inner ends at the middle portion of the plate.

3. A tie-plate consisting of an integral metal plate having on its under surface two series of ribs, one series extending from near one edge to beyond the middle transverse line of the plate, the two series overlapping each other at their inner ends at the middle portion of the plate, and similar elongated but shorter ribs supplemental to said long ribs in the spaces at the ends of the long ribs but separated a distance therefrom.

4. A tie-plate comprising an integral metal plate having on its under surface two series of parallel ribs, one series extending from near one edge to beyond the middle transverse line of the plate, and the other series extending from near the opposite edge of the plate to beyond the middle transverse line of the plate, the two series overlapping each other at their inner ends at the middle portion of the plate, and similar elongated but shorter ribs supplemental to said long ribs in the spaces at the ends of the long ribs but separated a distance therefrom, the ribs being severally out of endwise alinement with every other rib on the plate.

707,868. GALVANIC BATTERY. Hazen L. Sloour, Pawtucket, R. I. Filed July 1, 1901. Renewed July 23, 1902. Serial No. 116,066. (No model.)

Claim.—1. In a galvanic battery a carbon or negative element made a four divisions, each division having in cross-section the form of a letter W forming ribs on both the outside and inside of the carbon in combination with zinc elements held in the spaces between the divisions, and a containing-jar, substantially as described.

2. In a galvanic battery the combination of a plurality of positive elements, a containing-jar having a separate amalgamating-cup for each positive element made in its bottom, a carbon element made in four divisions, each division having in cross-section the form of a letter W with said positive or zinc elements held in the spaces between said divisions, substantially as described.

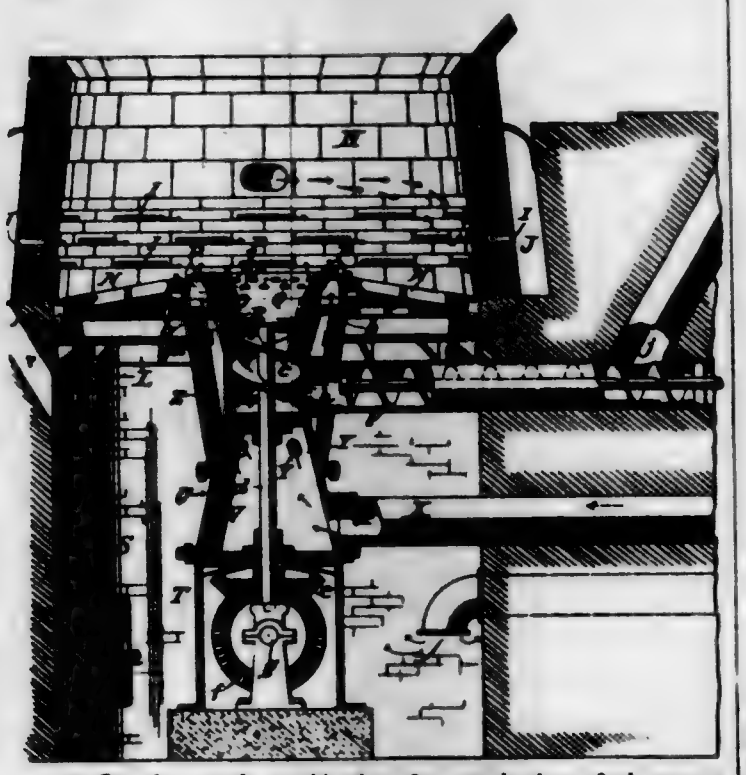
3. In a galvanic battery, a carbon element composed of inside and outside vertical ribs separated into sections and joined together at the top the whole having a hollow center, the zinc electrodes in combination with a suitable jar for containing said carbon and the zinc electrodes, substantially as described.

4. In a galvanic battery, a carbon element with a hollow center, inwardly and outwardly extending vertical ribs, tapering in cross-section, separated into two or more sections joined together at the top in combination with a jar having a plurality of cups in its lower end, a plurality of positive electrodes or zinc rods held in said cups substantially as described.

5. In a galvanic battery, a jar having its bottom made of a plurality of cups, a carbon element with a hollow center, a series of internal and external vertical ribs, joined together at their upper ends and divided at their lower parts into groups, in combination with a plurality of positive elements set between said ribs with their lower ends extending down into said cups substantially as described.

707,864. HEATING APPARATUS. Isaac D. Shead, Cincinnati, Ohio. Filed July 30, 1901. Serial No. 70,137. (No model.)

Claim.—1. In a furnace, the combination of a grate having a central perforate collar; a shell located below the grate and having two compartments or chambers V and W, the latter opening into the collar; a feed-screw mounted in said upper chamber W; means for forcing air into the lower chamber; and a sleeve surrounding the shell, said sleeve serving to form a passage for air passing from chamber V to the perforate collar.



2. In a furnace, the combination of a grate having a feed-opening; a fuel-chamber located beneath the grate and in line with the opening; a feed-screw located in said chamber; and a separate and independent feed-conduit leading to the upper side of the grate, substantially as and for the purpose specified.

3. In a furnace, the combination of a grate; an under fuel-feed for said grate; and a conduit or pipe leading from the fuel-supply and discharging at a point above the grate.

4. In a furnace, the combination of a grate having a central feed-opening; means for forcing fuel from below up through said opening to the grate; a boiler drum or section located above the grate; and a fuel conduit or pipe extending through said boiler-section and discharging upon the upper side of the grate.

5. In a furnace, the combination of a grate having a central opening; a chamber located below the grate and in line with said opening; a feed-screw mounted in said chamber; means for feeding fuel into the chamber; a boiler-section mounted above the grate; and a fuel-feed conduit extending through said section and discharging onto the upper face of the grate.

707,865. PLANE. ALIX W. STANLEY, New Britain, Conn., assignor to the Stanley Rule & Level Company, New Britain, Conn., a Corporation of Connecticut. Filed Mar. 5, 1902. Serial No. 96,772. (No model.)

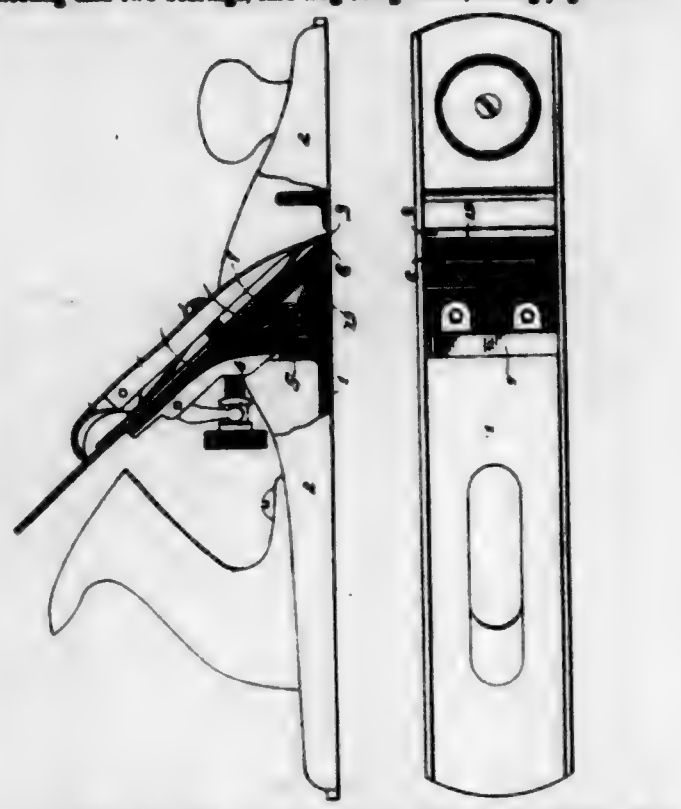
Claim.—1. In a plane, the combination with the stock, a frog, a plurality of bearings on said stock for said frog, and a clamping device located between said bearings, a slot or throat in the bottom or floor of said stock portion, the bottom or floor of said stock portion to the rear of said throat being thinned out up to the edge thereof, and means for strengthening said thinned-out floor.

2. In a plane, the combination with a stock having a plurality of seats for a detachable frog of a throat extending transversely of the stock and in the bottom thereof, the floor of said stock directly to the rear of said throat being of thin metal, and strengthening-ribs extending from the heavy part of said stock to said thinned-out portion, substantially as described.

3. A stock for a plane having a transverse slot therein forming a throat for the passage of the plane-iron, the floor to the rear of said throat being thin, the stock to the rear of said thin portion of the floor being heavy, and a rib extending from said heavy portion to said thin portion, and strengthening and supporting the latter.

4. In a plane, a stock, a transverse slot therein forming a throat for the passage of the plane-iron, the floor to the rear of said throat being thin, the stock to the rear of said thin portion of the floor being heavy, and a plurality of ribs extending from said heavy portion to said thin portion and strengthening and supporting the latter.

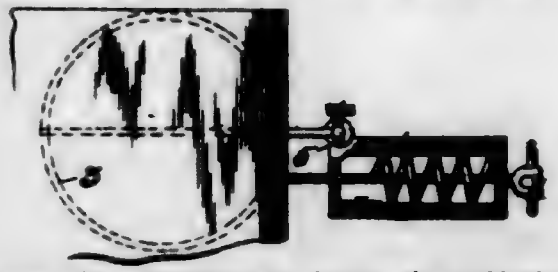
5. A plane having a stock portion provided with a throat, a frog, said stock portion being provided with two bearings for said frog, a rib connecting said two bearings, said frog being correspondingly grooved.



6. A plane having a stock portion provided with a throat, a frog, said stock portion being provided with an upper and a lower bearing for said frog, a rib connecting said two bearings, said frog being correspondingly grooved.

7. A plane having a stock portion provided with a throat, a frog, said stock portion being provided with an upper and a lower bearing for said frog, a screw having a seat between said bearings for securing said frog to said stock, a rib connecting said two bearings, said frog being correspondingly grooved.

707,866. STOVE-DAMPER ATTACHMENT. JAMES R. STOVER, Curwensville, Pa. Filed Feb. 21, 1902. Serial No. 95,116. (No model.)



Claim.—1. In an attachment for dampers, the combination of a damper and the damper-casing, a handle secured to said damper, a casing, a spring-pressed plunger within the casing, an angular arm secured to the casing and having an opening in its end to receive the damper-handle, and means for retracting the said plunger.

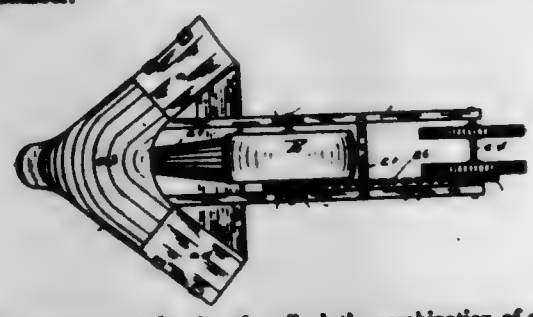
2. In an attachment for dampers and the like, the combination with the damper having a handle, a casing attached to said handle, a spring-pressed plunger secured in said casing and adapted to normally engage the damper-casing, and an operating-handle fulcrumed upon said casing for retracting said spring-pressed plunger, substantially as described.

3. In an attachment for dampers, the combination with the damper, and a handle secured thereto, of a casing, an angular extension on one end of the said casing and having an opening in its end to receive the damper-handle, a thumb-screw secured in the said extension adjacent the opening therein, a spring-pressed plunger secured in said casing and adapted to normally engage the damper-casing, and an operating-handle fulcrumed upon said casing for retracting said plunger.

707,867. MACHINE FOR CLEANING STREETS. JOSEPH THIRY, Joliet, Ill. Filed Dec. 23, 1901. Serial No. 86,901. (No model.)

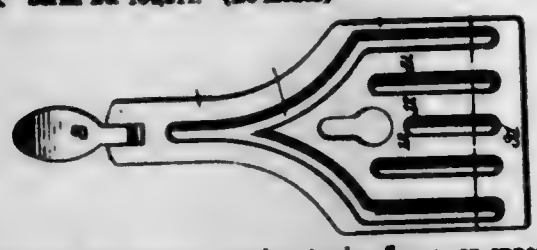
Claim.—1. A machine for cleaning streets of snow and ice, composed of a wedge-shaped combustion-chamber having a grated bottom and with openings at the top for the escape of the products of combustion, a frame secured at the rear of said chamber, ground-wheels supporting said frame, a fan-case supported on said frame and having a tapering nozzle extending therefrom, a rotatable fan mounted within the fan-case and means for driving said fan, and means communicating with said in-

porous nozzle whereby the air from said case may be distributed throughout said chamber.



2. In a machine of the class described, the combination of a wedge-shaped combustion-chamber having a grated bottom and with openings at the top for the escape of products of combustion, a frame secured at the rear of said chamber, ground-wheels supporting said frame, a fan-case secured to said frame, a rotatable fan mounted in said case, means for driving said fan from the ground-wheels, a nozzle projecting from and communicating with the fan-case, pipes located within the combustion-chamber, having air-openings therein and communicating with said nozzle, substantially as set forth.

707,868. PLANE-IRON CAP. JUSTUS A. TRAUT and HENRY S. WALKER, New Britain, Conn., assignors to Stanley Rule and Level Company, New Britain, Conn., a Corporation of Connecticut. Filed Apr. 28, 1902. Serial No. 104,811. (No model.)



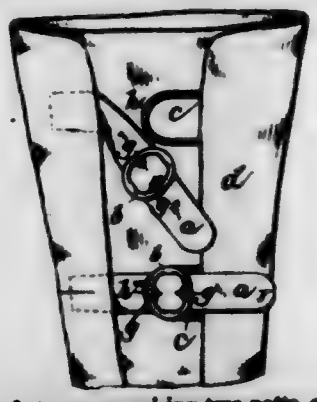
Claim.—1. In a plane, a cap-iron having flanges on opposite sides at its upper end, and ribs extending longitudinally of said iron.

2. A plane-iron cap for a plane having corrugations or ribs extending longitudinally thereof, substantially as described.

3. A plane-iron cap for a plane having corrugations or ribs 12 and 12 in the body and extending longitudinally thereof, as described.

4. A plane-iron cap for a plane having corrugations or ribs 11 extending up the shank and 12, 12 in the body extending longitudinally thereof, substantially as described.

707,869. FASTENER. JAY R. TRAVER, Naugatuck, Conn., assignor to the Goodyear's Metallic Rubber Shoe Company and the Goodyear's India Rubber Glove Manufacturing Company, Naugatuck, Conn., Corporations of Connecticut. Filed July 6, 1900. Serial No. 22,894. (No model.)

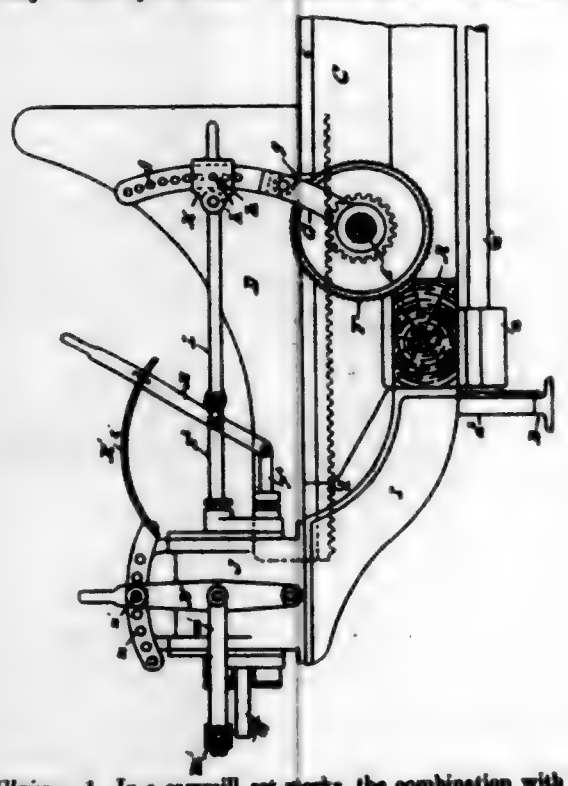


Claim.—1. A fastener comprising two parts, one part consisting of a tab with an adjustable slide thereon and the other part consisting of a loop provided with an opening therein, the dimensions of the slide and opening being so related that in one position thereof, with the slide and loop substantially parallel, the slide may be passed through the opening in the loop, and in the normal position thereof, with the slide and loop engaged, a portion of the margin of the slide will bear against the loop about the opening, the slide having a cross-bar with one or more projections thereon whereby it grips the tab and retains the position to which it is adjusted upon the tab and is not disturbed therefrom by engagement or disengagement of the slide and loop, substantially as set forth.

2. The combination with a tab and a slide thereon, the slide having a cross-bar with one or more projections thereon, of a loop constructed to engage between the tab and slide and having an opening therein narrower than the slide and longer than the greatest dimension thereof, substantially as set forth.

3. A fastener comprising two parts, one part consisting of a tab and a slide, such slide *b* having a middle cross-bar *e* with projections *f* thereon and outer curved cross-bars *g*, *g*, and the other part consisting of a loop having an opening narrower than the slide and longer than the greatest dimension of the slide and wider than the tab, substantially as set forth.

707,870. SAWMILL SET-WORKS. JOHN WALTON, Erie, Pa., assignor of one-half to Allis-Chalmers Company, a Corporation of New Jersey. Filed Apr. 28, 1900. Serial No. 14,757. (No model.)



Claim.—1. In a sawmill set-works, the combination with the log-moving mechanism; of an engine for actuating said mechanism comprising a working piston; a cylinder in which said piston operates; and means for lengthening or shortening the working portions of said cylinder for varying the movement of the set-works.

2. In a sawmill set-works, the combination with the log-moving mechanism; a working piston for actuating said mechanism; a cylinder in which said piston operates; a setting-piston in said cylinder; and means for locking the setting-piston in different positions in said cylinder varying the working length of said cylinder.

3. In a sawmill set-works, the combination with the knee; a ratchet-lever for effecting a movement of said knee; a block on said ratchet-lever; means for locking said block at different points upon said lever to vary the movement of said lever with an equal movement of the block; a working piston connected with said block; a cylinder in which said piston is arranged to operate; and means for lengthening or shortening the working portions of said cylinder for varying the movement of said piston.

4. In a sawmill set-works, the combination with the knee; a ratchet lever for effecting movement of said knee; a block on said ratchet-lever; means for locking said block at different points upon said lever to vary the movement of said lever with an equal movement of the block; a working piston connected with said block; a cylinder in which said piston is arranged to operate; a setting-piston in said cylinder; and means for locking said piston in different positions in said cylinder for varying the working length of said cylinder.

5. A sawmill set-works comprising the combination with a log-moving mechanism; of an engine arranged to operate said log-moving mechanism; and automatic means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means by the active power of the engine from a rapid intermediate movement to a slow end movement.

6. A sawmill set-works involving the combination with a log-moving mechanism; an engine arranged to operate said log-moving mechanism; means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means by the active power of the engine, from a rapid intermediate movement to a slow end movement; and a positive stop for engaging said mechanism during the slow end movement.

7. A sawmill set-works involving the combination with a log-moving mechanism, comprising a ratchet device; of an engine arranged to operate said log-moving mechanism through said ratchet device; and means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement.

8. A sawmill set-works, involving the combination with a log-moving mechanism; of an engine comprising a working piston arranged to operate said log-moving mechanism; and means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means by the active power of the engine from a rapid intermediate action to a slow end movement, by similarly varying the speed of the piston.

9. A sawmill set-works involving the combination with a log-moving mechanism, comprising a ratchet device; of an engine to operate said log-moving mechanism through said ratchet device; and means for causing a variation in the speed at which said log-moving mechanism is driven, from a rapid intermediate movement to a slow end movement, by similarly varying the speed of the piston.

10. A sawmill set-works involving the combination with the log-moving mechanism comprising a ratchet device; of an engine comprising a working piston for operating said log-moving mechanism through said ratchet device; means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means by the active power of the engine from a rapid intermediate movement to a slow end movement; and means for varying the extent of movement of the log-moving mechanism with a single movement of the piston.

11. A sawmill set-works involving the combination with the log-moving mechanism, comprising a working piston for operating the said log-moving mechanism; means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means from a rapid intermediate movement to a slow end movement; means for varying the extent of movement of the log-moving mechanism with a single movement of the piston; and a positive stop arranged to come into engagement during the slow end movement of the mechanism.

12. A sawmill set-works involving the combination with the log-moving mechanism comprising a ratchet device; of an engine comprising a working piston for operating said log-moving mechanism through said ratchet device; means for causing a variation from the speed at which the log-moving mechanism would be driven but for said means by the active power of the engine from a rapid intermediate movement to a slow end movement by a similarly varying speed of the piston; and means for varying the extent of a single movement of the log-moving mechanism by varying the extent of movement of the piston.

13. A sawmill set-works involving the combination with the log-moving mechanism, comprising a ratchet device; of an engine comprising a working piston for operating said log-moving mechanism through said ratchet device; means for causing a variation from the speed at which the log-moving mechanism would be driven but for said mechanism by the active power of the engine from a rapid intermediate movement to a slow end movement; means for varying the extent of movement of the log-moving mechanism with a single movement of the piston; and a positive stop for engaging said mechanism during a slow end movement.

14. A sawmill set-works, involving the combination with a log-moving mechanism, comprising a ratchet device; an engine for actuating said mechanism through said ratchet device comprising a working piston; and a means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement comprising a cushion device arranged to operate only at the end of the stroke of the piston.

15. A sawmill set-works involving the combination with a log-moving mechanism, comprising a ratchet device; an engine for actuating said mechanism through said ratchet device comprising a working piston; and means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushion device arranged to operate only at the end of the stroke of the piston; and a positive stop for the engine.

16. A sawmill set-works involving the combination of a log-moving mechanism, comprising a ratchet device; an engine for actuating said mechanism, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushion device arranged to operate only at the end of the stroke of the piston; and means for varying the movement given to the log-moving mechanism by a single stroke of the piston.

17. A sawmill set-works involving the combination of a log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushion device arranged to operate only at the end of the stroke of the piston; and means for varying the stroke of the piston to vary the movement given to the log-moving mechanism.

18. A sawmill set-works involving the combination of the log-moving mechanism; an engine for actuating said mechanism, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushion device arranged to operate only at the end of the stroke of the piston; a positive stop; and means for adjusting the position of said stop to vary the stroke of the piston.

19. A sawmill set-works involving the combination with the log-moving mechanism, comprising a ratchet device; an engine for actuating said mechanism through said ratchet device, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushioning device arranged to operate only at the end of the stroke of the piston; a positive stop; and means for adjusting the position of said stop to vary the stroke of the piston.

20. A sawmill set-works involving the combination of the log-moving mechanism; an engine for actuating said mechanism, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushioning device arranged to operate only at the end of the stroke of the piston; a positive stop; and means for adjusting the cushion device and positive stop to vary the stroke of the piston and the point in the stroke of the piston at which the cushion device begins to operate.

21. A sawmill set-works involving the combination with the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushioning device arranged to operate only at the end of the stroke of the piston; a positive stop; and means for adjusting the cushioning device and positive stop to vary the stroke of the piston and the point in the stroke of the piston at which the cushioning device begins to operate.

22. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushion device arranged to operate only at the end of the stroke of the piston, said cushion device comprising a plunger and fluid-chamber arranged to be brought into action only at the end of the stroke of the piston, and to impriscn a cushioning fluid by said action; means for permitting a gradual escape of said cushioning fluid to allow the mechanism to move to a positive stop; said stop; and means for adjusting said stop to vary the stroke of the piston and the action of the log-moving mechanism.

23. A sawmill set-works involving the combination of the log-moving mechanism; an engine for actuating said mechanism, comprising a working piston; a positive stop arranged to limit the stroke of the piston; means for adjusting said stop to vary the stroke of the piston and the action of the log-moving mechanism; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushioning device on said stop arranged to be brought into action only at the end of the stroke of the piston, said cushion device being arranged to be adjusted with the stop.

24. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device, comprising a working piston; a positive stop arranged to limit the stroke of the piston; means for adjusting said stop to vary the stroke of the piston and the action of the log-moving mechanism; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow end movement, comprising a cushioning device on said stop arranged to be brought into action only at the end of the stroke of the piston, said cushioning device being arranged to be adjusted with the stop.

25. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven, from a rapid intermediate movement to a slow movement at each end, comprising a cushioning device arranged to operate only at the ends of the stroke of the piston; positive stops at both ends of the stroke of the piston for controlling the length of the stroke; and means for adjusting the position of one of said stops to vary the stroke of the piston and the action of the log-moving mechanism.

26. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device, comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow movement at each end, comprising a cushioning device arranged to operate only at the ends of the stroke of the piston; positive stops at the end of the stroke

of the piston for controlling the length of the stroke; means for varying one of said stops and the cushion device to vary the stroke of the piston and the point in the stroke of the piston at which the cushion device is brought into action.

27. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device comprising a working piston; means for causing a variation in the speed at which the log-moving mechanism is driven, from a rapid intermediate movement to a slow movement at each end, comprising cushion devices arranged to operate only at the ends of the stroke of the piston, said cushion devices each comprising a plunger and fluid-chamber arranged to be brought into action only at the ends of the stroke of the piston and to imprison a cushioning fluid by said action; means for permitting a gradual escape of said cushioning fluid to allow the mechanism to move to positive stops for each end of the stroke; and means for adjusting one of said stops to vary the stroke of the piston and the action of the log-moving mechanism.

28. A sawmill set-works involving the combination of the log-moving mechanism comprising a ratchet device; an engine for actuating said mechanism through said ratchet device comprising a working piston; stops arranged at each end of the piston and in position to limit the stroke of the piston; means for causing a variation in the speed at which the log-moving mechanism is driven from a rapid intermediate movement to a slow movement at each end, comprising cushioning devices carried by said stops, said cushioning devices each comprising a plunger and fluid-chamber, arranged to be brought into action only at the ends of the stroke of the piston and to imprison a cushioning fluid by said action; means for permitting a gradual escape of said cushioning fluid to allow the mechanism to move to a positive stop; and means for adjusting one of said stops and cushioning mechanism to vary the stroke of the piston at the point at which the cushion device is brought into action.

29. In a sawmill set-works, the combination of the log-moving mechanism; a working piston for actuating said mechanism; a cylinder in which said piston operates; a setting-piston arranged in said cylinder; means for locking the said setting-piston in different positions in said cylinder; an exhaust-port extending through said setting-piston; a plug on the working piston arranged to enter said exhaust-port, said port and plug being of such size relatively to each other that the plug approximately but not entirely closes said port.

30. In a sawmill set-works, the combination with the log-moving mechanism; of an engine for actuating said set-works comprising a working piston, and a cylinder in which said piston operates; means for lengthening or shortening the working portions of said cylinder for varying the movement of said working piston; a valve for controlling the movement of fluid to and from said cylinder; a valve-lever for operating said valve; a connection for connecting said lever with the working piston, whereby said piston forms a moving fulcrum for the lever.

31. In a sawmill set-works, the combination with the log-moving mechanism; of an engine for actuating said set-works comprising a working piston and a cylinder in which said piston operates; means for lengthening or shortening the working portions of said cylinder for varying the movement of said working piston; a valve for controlling the movement of fluid to and from said cylinder; a valve-lever for operating said valve; a connection for connecting said lever with the working piston; and means for locking said lever at various positions in proper relation to the means varying the length of the working cylinder to effect a secondary movement of the valve after the setting of said valve-lever to bring the valve to normal.

32. In a sawmill set-works, the combination of a log-moving mechanism; the working piston, K, for moving said mechanism; a cylinder in which said working piston operates; a setting-piston in said cylinder; piston-rod, *m*, extending from said setting-piston; the lever, N; means for connecting said lever with the piston-rod, *m*; the quadrant, N'; means for locking the lever, N, with the quadrant, N'; a valve for controlling the movement of steam to and from the cylinder; a lever, R, for operating said valve; a connection between said lever and the working piston; the quadrant, R'; means for setting the lever, R, on said quadrant at different positions relatively to the different positions of the setting-piston, M, to effect a secondary movement of the valve, through the movement of the lever, as effected by the movement of the working piston, after the setting of the lever, R, to bring the valve to normal.

33. In a sawmill set-works, the combination of the log-moving mechanism; the working piston, K, for effecting the movement of said mechanism; a cylinder in which said piston operates; a setting-piston, M; piston-rod, *m*, extending therefrom; the lever, N; means for connecting said lever with said rod, *m*; a quadrant, N'; means for locking the lever, N, with said quadrant; steam-chests having ports leading therefrom to the opposite ends of the cylinder; means for conveying the steam by the setting-piston, M; a valve in the steam-chest; and means for actuating said valve.

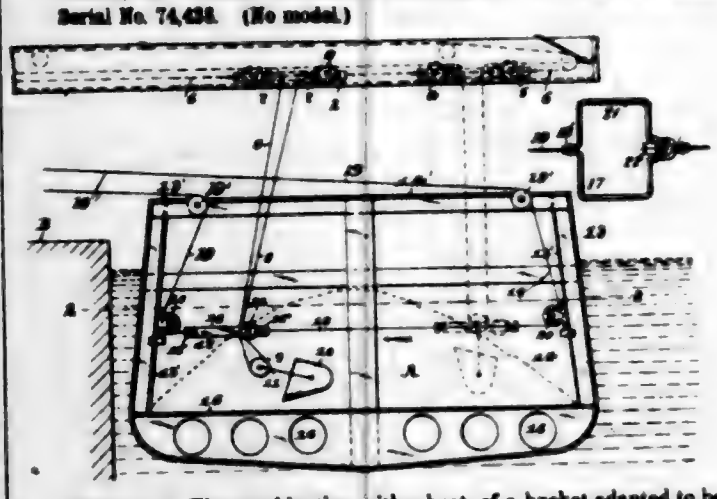
34. In a sawmill set-works, the combination of a log-moving mechanism; a working piston for effecting the movement of said mechanism; a cylinder in which said piston operates; a setting-piston in said cylinder; means for locking said setting-piston in various positions in said cylinder; means for conveying the live steam by said setting-piston; an exhaust-port extending through said setting-piston; a plug on the working piston arranged to enter said exhaust-port and to approximately but not entirely close said port.

35. In a sawmill set-works, the combination of the log-moving mechanism; a working piston, K, for effecting the movement of said mechanism; a cylinder in which said piston operates; a setting-piston arranged in said cylinder and having the opening, m^3; means for locking said setting-piston in various positions in said cylinder; a port tube, Q, arranged in the setting-piston; a steam-chest; means for connecting the port-tube, Q, therewith; the plug, *k'*, arranged in relation to the opening, m^3, as described.

36. In a sawmill set-works, the combination of the log-moving mechanism; a working piston, K, for effecting the movement of said mechanism; a cylinder in which said piston operates; a setting-piston arranged in said cylinder and having the opening, m^3, and port, m^3, connecting the portions of the cylinder on the opposite sides of the setting-piston, M; means for locking said setting-piston in various positions in said cylinder; a port-tube, Q, arranged in the setting-piston; a steam-chest; and means for connecting the port-tube, Q, therewith.

37. In a sawmill set-works, the combination with the log-moving mechanism; the ratchet-lever, G, for effecting this movement; the block, H, thereon; the connecting-rod, L, secured to said block; the piston-rod, *k*, secured to said connecting-rod; the piston, K, also secured to the piston-rod; the cylinder, J, in which the said piston operates; the setting-piston, M, also in said cylinder; piston-rod, *m*, extending from the setting-piston and having the opening, m^3, and port m^3, therein; the lever, N; means for connecting the piston-rod, *m*, with said lever; the quadrant, N', means for locking the lever, N, with said quadrant; the port-tube, Q, extending through the piston, M; steam-chest, O, having the ports, *o*, *o'* and o^3, leading therefrom to the ends of the cylinder; the port, *o*, connecting with the port-tube, Q, the port, *o'*, with the rear end of the cylinder, the port, o^3 and o^3, with the front end of the cylinder; the valves, *p'* and p^3, controlling said ports; the central portion, *p*, into which the port, p^3, enters; the lever, R, connected with said valve; the link, *r*, connecting said valve-lever with the rod, *k*; the quadrant, R', having the notches, *r*, arranged as described and for the purposes described.

707,871. APPARATUS FOR REMOVING MATERIAL FROM BOATS, &c. ALFRED M. ACKLIN, Pittsburg, Pa. Filed Sept. 5, 1901. Serial No. 74,438. (No model.)



Claims.—1. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a deflecting-frame, and means connected to said frame for moving the same to tilt the bucket and move the same in a horizontal course to gather the material therein.

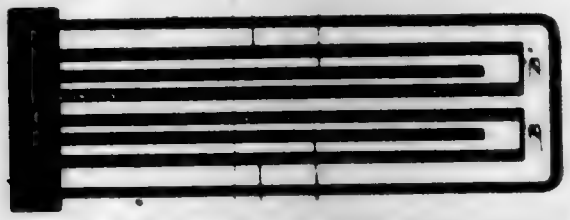
2. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a movable deflecting-frame, drums or sheaves within said hold, and a rope or cable connected to said frame and drums or sheaves for moving said frame to tilt the bucket and move the same in a horizontal course to gather the material therein.

3. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, and a movable deflecting-frame adapted to engage with the bucket to tilt and move the same in a horizontal course to gather the material therein, said frame having an opening therein to permit the bucket to be lowered and raised through the same to and from the material in the hold.

4. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat by ropes or cables, a movable deflecting-frame adapted to engage with the bucket to tilt and move

the same in a horizontal course to gather the material therein, said frame having an opening therein to permit the bucket to be lowered and raised through the same to and from the material in the hold, and a sheave on said frame for engaging with the ropes or cables during the movement of said frame and bucket.

707,872. ELECTROCHEMICAL GENERATOR. HARRY S. ANWAKE, Camden, N. J., assignor to Charles H. Graham and George D. Bouton, Philadelphia, Pa. Filed June 13, 1902. Serial No. 111,556. (No model.)



Claim.—1. An electrochemical generator consisting of a single-fluid cell, provided with a positive electrode, a negative electrode, an electrolyte and current-conducting baffles in said electrolyte respectively surrounding each of said electrodes and normally insulated therefrom, substantially as described.

2. An electrochemical generator consisting of a single-fluid cell, provided with a positive electrode, a negative electrode, and an electrolyte, current-conducting baffles in said electrolyte respectively surrounding each of said electrodes and normally insulated therefrom, and means for placing in parallel circuit each electrode and its surrounding baffle.

3. An electrochemical generator consisting of a single-fluid cell provided with a positive electrode, a negative electrode, an electrolyte and mechanically-connected current-conducting baffles in said electrolyte respectively surrounding each of said electrodes and normally insulated therefrom, substantially as described.

707,873. ANTHRACENE DYE AND PROCESS OF MAKING SAME. OSCAR BALLY, Mannheim, Germany, assignor to Badische Anilin & Soda Fabrik, Ludwigshafen, Germany, a Corporation of Germany. Filed July 2, 1901. Serial No. 66,897. (No specimens.)

Claim.—1. The process of manufacturing coloring-matters by condensing halogenized amido-anthraquinone substances with the sulfo-acids of primary aromatic amins.

2. The process of manufacturing coloring-matters by condensing halogenized amido-anthraquinone substances with the sulfo-acids of primary aromatic amins and sulfonating the products thus obtained.

3. The new coloring-matters such as can be obtained by condensing halogenized amido-anthraquinone substances with the sulfo-acids of primary aromatic amins, and sulfonating if increased solubility in water is desired, and which are characterized by the following properties: soluble in water giving a blue-green to violet solution; soluble in concentrated sulfuric acid in the presence of boric acid giving greenish to bluish or violet solutions; soluble in concentrated sulfuric acid alone giving reddish to bluish or violet colored solutions.

707,874. ANTHRACENE DYE AND PROCESS OF MAKING SAME. OSCAR BALLY, Mannheim, Germany, assignor to Badische Anilin & Soda Fabrik, Ludwigshafen, Germany, a Corporation of Germany. Filed July 2, 1901. Serial No. 66,898. (No specimens.)

Claim.—1. The process of manufacturing coloring-matter of the anthracene series by condensing sulfo-acids of primary aromatic amins with nitro-anthraquinone substances.

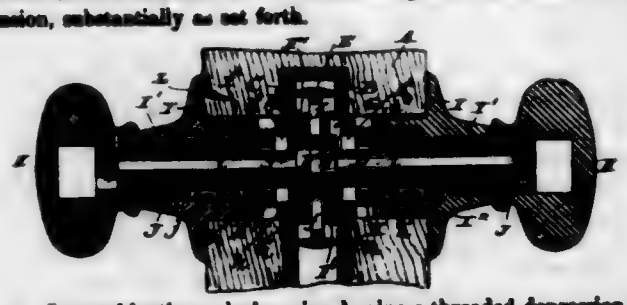
2. The process of manufacturing coloring-matter of the anthracene series by condensing sulfanilic acid with nitro-anthraquinone substances.

3. As a new product the coloring-matters of the anthracene series which can be obtained by condensing a sulfo-acid of a primary aromatic amin with a nitro-anthraquinone substance; which are soluble in water with a reddish-brown to violet-blue color; soluble in glacial acetic acid with a reddish to orange color; soluble in concentrated sulfuric acid with a yellow-brown to violet color.

707,875. KNOB ATTACHMENT. WILLIAM S. BARTHOLOMEW, Wyncote, Pa., assignor to the Adams & Westlake Company, of Illinois. Filed Apr. 16, 1902. Serial No. 103,194. (No model.)

Claim.—1. In combination, a lock-casing having a threaded depression in its side, a rose provided with an integral extension having a threaded bore and adapted under certain conditions to enter said depression in the lock-casing, and a threaded thimble connecting said depression with said extension, substantially as set forth.

2. In combination, a lock-casing provided with a threaded depression in its side, a rose having an inwardly-projecting cylindrical extension with a threaded bore and being also circumferentially threaded to adapt said extension to engage under certain conditions the said threaded depression, and a threaded thimble connecting said depression with said extension, substantially as set forth.



3. In combination, a lock-casing having a threaded depression in its side, a cylindrical extension projecting inwardly from a rose, having a threaded bore and being circumferentially threaded, and a threaded thimble of greater diameter at one end than at the other, and adapted to connect said depression with said cylindrical extension, substantially as set forth.

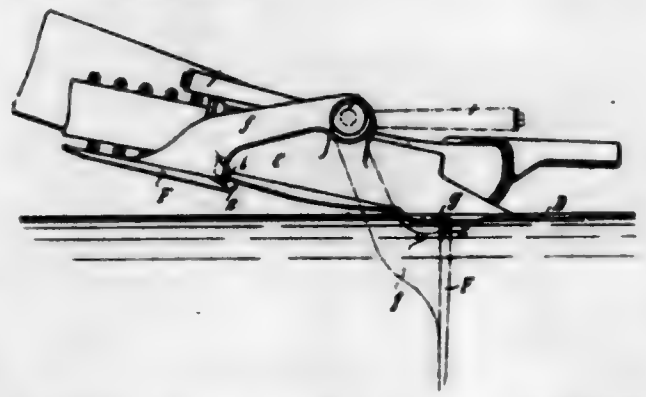
4. In combination, a lock-casing having a threaded depression in its side, a rose provided with an extension having a threaded bore, a thimble having two diameters for connecting said casing with said extension, a sleeve passing through the rose and adapted to rotate therein, and a knob or handle secured to the sleeve, substantially as set forth.

5. In combination, a lock-casing having a threaded depression in its side, a rose having a cylindrical extension projecting inwardly and provided with a threaded bore, a thimble, having a greater diameter at one end than at the other, for connecting the casing with the rose, a polygonally-bored sleeve passing through the rose and adapted to rotate therein, a knob or handle secured to the sleeve, and a spindle, polygonal in cross-section, adapted to slide in the sleeve, substantially as set forth.

6. In combination with a lock-casing and its cover-plate, each having a threaded depression G formed with a flanged axial opening *g*, a hub or stump for operating a latch, said hub being journaled in the flanged openings *g*, substantially as set forth.

7. In combination in a lock, a casing and its cover-plate, each having a threaded depression formed therein, two thimbles, each being of greater diameter at one end than the other and adapted to engage each with one of said depressions, a rose on each side of the lock provided with a cylindrical extension having a threaded bore to engage the thimble on the same side of the lock, a sleeve passing through each rose and adapted to rotate therein, a knob or handle secured to each sleeve, and a polygonal spindle adapted to slide in a similarly-shaped bore in each sleeve, substantially as set forth.

707,876. GUN-CARRIAGE. OTTO BEHNKE, Essen, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Feb. 18, 1901. Serial No. 47,715. (No model.)



Claim.—1. In combination with a gun-carriage, a brake-spur swinging upon a pivot to and from its braking position, an eccentric bolt forming said pivot, having a rotation independent of the swinging movement of the spur, and means through which the spur engages the carriage, for locking the spur in braking and in inoperative positions, moved into and out of both locking engagements by the eccentric bolt.

2. The combination with a gun-carriage, of a pivotal eccentric bolt placed in connection with the carriage, a spur swung on said eccentric bolt, and interlocking parts placed respectively on the spur-carrier and on the spur to hold the spur in braking and in inoperative positions and adapted to be thrown into and out of engagement by the movements of the bolt, substantially as described.

3. In combination with a gun-carriage, a brake-spur swinging upon a pivot to and from its braking position, an eccentric bolt forming said pivot, having a rotation independent of the swinging movement of the

spur, means through which the spur engages the carriage for locking the spur in braking and in inoperative positions, moved into and out of both locking engagements by the eccentric of said bolt, and a lever for rotating the eccentric.

4. In combination with a gun-carriage, a braking-spur adjustable to braking position upon a pivot on said carriage, and also having a movement essentially radial to its pivot, and means for positively moving the spur radially and throwing it into engagement with the carriage for locking the spur in braking and in inoperative positions.

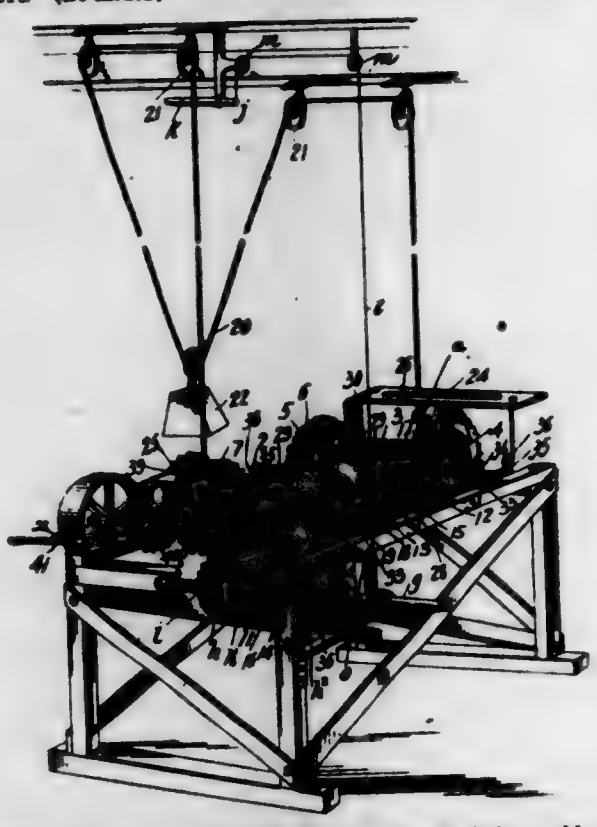
5. In combination with a gun, a braking-spur swinging about a pivot on said gun, from transport position to braking position, and having at each end of its swinging movement, a movement essentially radial to its pivot, and locking means at each end of the spur's path of swinging, by which the spur engages the carriage, engaged and disengaged with the spur by the latter's radial movement.

6. In combination with a gun-carriage; a braking-spur swinging about a pivot on said carriage, and also having a movement essentially radial in relation to its pivot, into and out of locking relation to the gun-carriage, locking means carried by the carriage and spur to lock the spur in braking and in inoperative positions, and brought into and out of engagement by the said radial movement of the spur, and a bolt carrying an eccentric providing the pivot for the spur, and having a rotating movement independent of the swinging movement of the spur.

7. In combination with a gun-carriage; a braking-spur swinging about a pivot on said carriage, and also having a movement essentially radial in relation to its pivot, into and out of locking relation to the gun-carriage, means adapted to lock the spur in braking and in inoperative positions and carried by the carriage and spur consisting of a projection on one part and a recess on the other brought into and out of engagement by the said radial movement of the spur, and a bolt carrying an eccentric providing the pivot for the spur, and having a rotating movement independent of the swinging movement of the spur.

707,877. WEIGHT-MOTOR AND GOVERNOR MECHANISM.

WILLIAM D. BELL, Slayton, Minn. Filed Oct. 10, 1901. Serial No. 78,214. (No model.)



Claim.—1. In a machine of the character described, the combination with suitably-journaled drums, of a rope or cable having its ends attached to said drums, a weight supported by said rope, a drive-shaft, and a shaft to be driven, gearing for transmitting motion from the drums in alternation, and means for applying the power to said drums from the drive-shaft, in alternation, substantially as set forth.

2. In a machine of the character described, the combination with suitably-journaled drums, of a rope or cable having its ends attached to said drums, a weight supported by said rope, a drive-shaft and a shaft to be driven, gearing for transmitting motion from the drums in alternation, means for applying the power to said drums from the drive-shaft, in alternation, and means for automatically shifting said first-named means, substantially as set forth.

3. In a machine of the character described, the combination with drums, of a rope or cable, the ends of which are secured to said drums, a weight supported by said rope or cable intermediate its ends, gear-wheels having a pawl-and-ratchet connection with said drums, a shaft to be driven, a gear constantly in mesh with the gears carried by said drums and geared up with the shaft to be driven, and means for rotating said drums in alternation, whereby as one drum rotates to wind up the rope or cable, the other drum may rotate to unwind the rope or cable, substantially as set forth.

4. In a machine of the character described, the combination with drums, beveled gear-wheels fixed to one end of said drums, gear-wheels having a pawl-and-ratchet connection with the opposite ends of said drums, a shaft to be driven, gearing interposed between the shaft to be driven and the last-named gear-wheels, a drive-shaft, mechanism for transmitting the movement from said drive-shaft to either one of the beveled gears, and means carried by the rope or cable for automatically actuating said mechanism, substantially as set forth.

5. In a machine of the character described, the combination with suitably-journaled drums, of gear-wheels carried thereby, a rope having its ends connected to said drums, a weight supported by said rope or cable, a drive-shaft, pinions loosely mounted on said drive-shaft and in mesh with said beveled gears, a clutch for locking either pinion to rotate said drive-shaft, pivoted bars having slots through which the rope passes, knots formed upon said rope of greater diameter than the slots, a clutch-shipper lever, and a connection between the clutch-shipper lever and the bars whereby, when one of said bars is elevated by the engagement therewith of one of the knots, the clutch will be shifted to throw one of the pinions out of operative engagement and the other pinion into operative engagement, substantially as set forth.

707,878. TIRE FOR VEHICLE-WHEELS.

EDOUARD BELLEDIGEAS and FREDERICK SONAURLIN DE MONDRAN, Paris, France. Filed May 10, 1902. Serial No. 106,805. (No model.)

Claim.—1. An elastic tire for vehicle-wheels comprising superposed flat springs, a tread-surface with which such springs are connected at their periphery, said springs being curved to follow the inner profile of the mass constituting the tread, a series of central rings, one ring for each set of superposed springs with their respective central rings: substantially as described.

2. An elastic tire for vehicle-wheels comprising sets of springs, each composed of an outer and inner spring with interposed flexible pieces between them, a suitable flexible tread-surface connected at the periphery of said springs, central rings, one for each set of springs, and rods connecting the springs with the rings: substantially as described.

3. An elastic tire for vehicle-wheels comprising sets of springs, each composed of an outer and inner spring with interposed flexible pieces between them, a suitable flexible tread-surface connected at the periphery of said springs, central rings, one for each set of springs, and rods connecting the springs with the rings, the vacant spaces longitudinal of the tire between each two sets of superposed springs, being provided with flexible filling material.

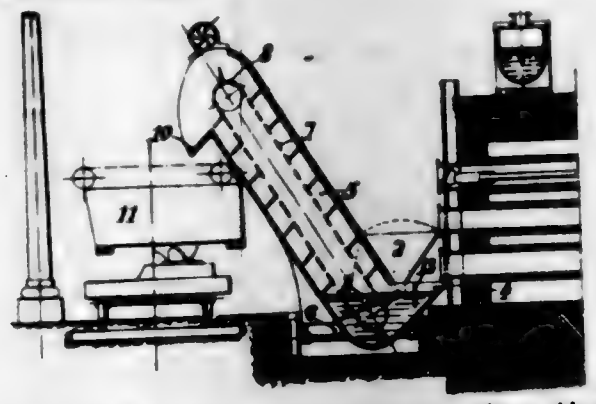
707,879. APPARATUS FOR QUENCHING OR COOLING COKE.

LÉON BERTRAND, Paris, France. Filed Feb. 3, 1902. Serial No. 92,732. (No model.)

Claim.—1. In an apparatus for quenching or cooling coke, the combination with a tank provided with a closed casing, of a hopper suitably attached to said tank, means in the casing of said tank for continuously discharging coke, means in said tank for submerging all the coke fed thereinto and means in said tank for carrying off the fluid generated by the coke while being immersed in the liquid contained in said tank.

2. In an apparatus for quenching or cooling coke, the combination with a water-tank provided with a closed casing, of a hopper hinged to said water-tank, an endless carrier in the casing of said water-tank, means in said water-tank for carrying off the steam generated by the coke while being immersed in the water contained in said water-tank, and means in said water-tank adjacent to the lower end of said hopper for causing the immersion of all the coke fed into said hopper.

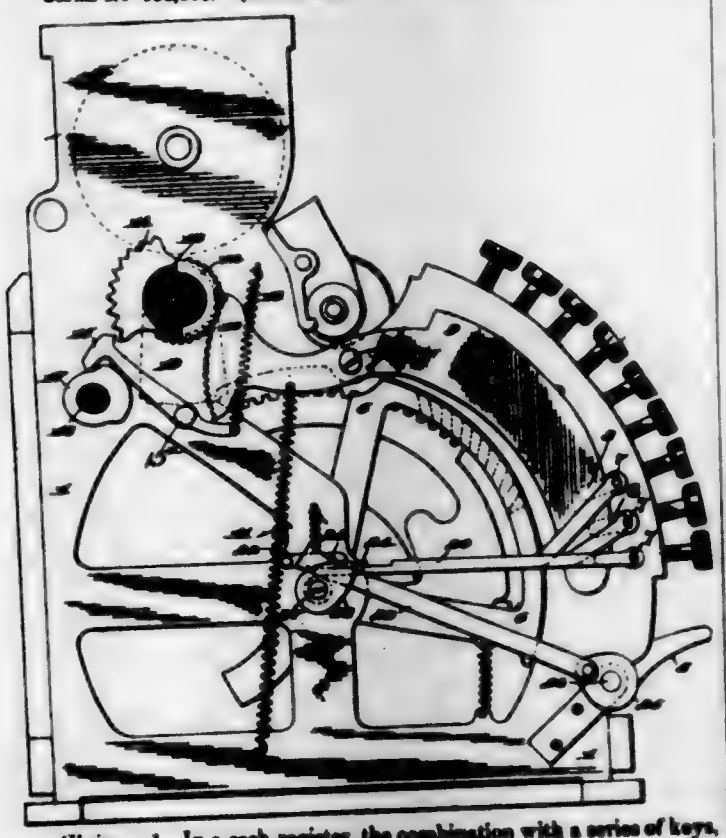
3. In an apparatus for quenching or cooling coke, the combination with a suitably-supported water-tank, of a hopper hinged to said water-tank, an endless carrier in the casing of said water-tank, a fan in the upper end of said water-tank, and a paddle in the lower end of said water-tank adjacent to said hopper.



4. In an apparatus for quenching or cooling coke, the combination with a suitably-supported water-tank, of a hopper hinged to said water-tank, an endless carrier in the casing of said water-tank, a fan in the upper end of said water-tank for carrying off the steam generated by the coke while being immersed in the water contained in said water-tank, a paddle in said water-tank adjacent to said hopper for causing the immersion of all the coke fed into said hopper, and means for operating said carrier, fan and paddle.

5. In an apparatus for quenching or cooling coke, the combination with a suitably-supported water-tank, of a hopper hinged to said water-tank, an endless carrier in the casing of said water-tank, a fan in the upper end of said water-tank for carrying off the steam generated by the coke while being immersed in the water contained in said water-tank, a paddle in said water-tank adjacent to said hopper for causing the immersion of all the coke fed into said hopper, and suitable electrical means and gearing for operating said carrier, fan and paddle.

707,880. CASH-REGISTER. FRANK H. BICKFORD, Dayton, Ohio, assignor, by mesne assignments, to National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Aug. 17, 1898. Serial No. 688,801. (No model.)



Claim.—1. In a cash-register, the combination with a series of keys, of locking devices for said keys, a release for said locking devices and means connecting said release with the operating parts of the machine for preventing its operation except when the mechanism is in normal position.

2. In a cash-register, the combination with a series of keys, a locking device for said keys, a driving mechanism, means for releasing said locking device independently of said driving mechanism and a lever arranged to coöperate with the driving mechanism to lock the releasing means except when the machine is in normal position.

3. In a cash-register the combination with a series of keys, of independent longitudinally-movable locking-bars pivoted respectively to said keys and each formed with a hook, and a single locking-pawl adapted to be moved by each of said hooks when the same engages therewith to release any previously-operated key.

4. In a cash-register the combination with a series of keys and a driving mechanism, of a series of movable locking-bars pivoted respectively to said keys, a single pawl arranged to be moved by each of said bars when it engages therewith and means for operating said pawl to disengage it from said bars when the machine is operated.

5. In a cash-register, the combination with a series of keys, and a driving mechanism, of locking-bars connected respectively to a portion of said keys, a detent arranged to lock said bars, means for releasing said detent and devices for raising said detent independently of the operation of the machine.

6. In a cash-register, the combination with a series of keys, of a detent having projections with which a part of said keys engage when operated and a reduced portion through which the remainder of the keys project when operated, independent detents for these latter keys, and an operating mechanism for operating all of the detents to release the keys.

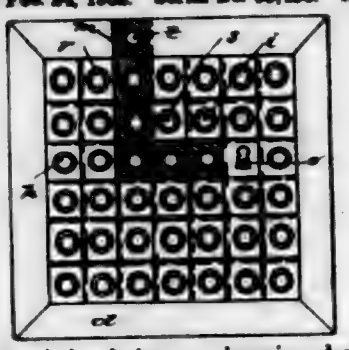
7. In a cash-register the combination with a series of keys, of independently-movable actuating locking-bars pivoted to said keys, and a single retaining-pawl to which said bars become latched and adapted to be moved by each of the same when it engages therewith to release any previously-latched bar.

8. In a cash-register, the combination with a series of keys, of a locking device for said keys, a release for said locking device, an operating-lever for said release, and a controlling-lever connected to the operating-lever and engaging the operating parts of the machine for preventing any movement of said operating-lever except when the mechanism is in normal position.

9. In a cash-register, the combination with a series of keys, of locking devices for said keys, means for releasing said devices upon the operation of the machine, independent means for releasing said devices upon the operation of the machine, independent release means for said latter locking devices, and devices for preventing the operation of the latter release means except when the machine is in normal position.

10. In a cash-register, the combination with a series of keys, of locking devices for said keys, means for releasing said devices at will, a lever controlled by said means, and a notched wheel connected to the movable parts of the machine and coöperating with said lever for preventing the operation of the release devices except when the register mechanism is in normal position.

707,881. KEYHOLE-GUARD. FLORIS H. BOS, Hoogland, Netherlands. Filed Feb. 24, 1902. Serial No. 96,490. (No model.)



Claim.—1. A keyhole closing or obscuring device, comprising a base or mounting plate, a plurality of connected movable plates arranged over said base-plate, and a plurality of slide-pieces carrying upon their outer surfaces certain of said first-mentioned plates, and means for guiding said slide-pieces; substantially as described.

2. A keyhole closing or obscuring device, comprising a mounting-plate, a plurality of small square plates arranged in a regularly-divided field over said plate, means of engagement between said small plates adapted to permit them to move laterally relatively to each other, a plurality of slide-pieces arranged in such manner that one of them cannot be moved until the next has been moved, a plurality of said small square plates arranged on the outer surface of each slide-piece, means for guiding said slide-pieces and means for connecting said small square plates to the mounting-plate and the slide-pieces from the rear.

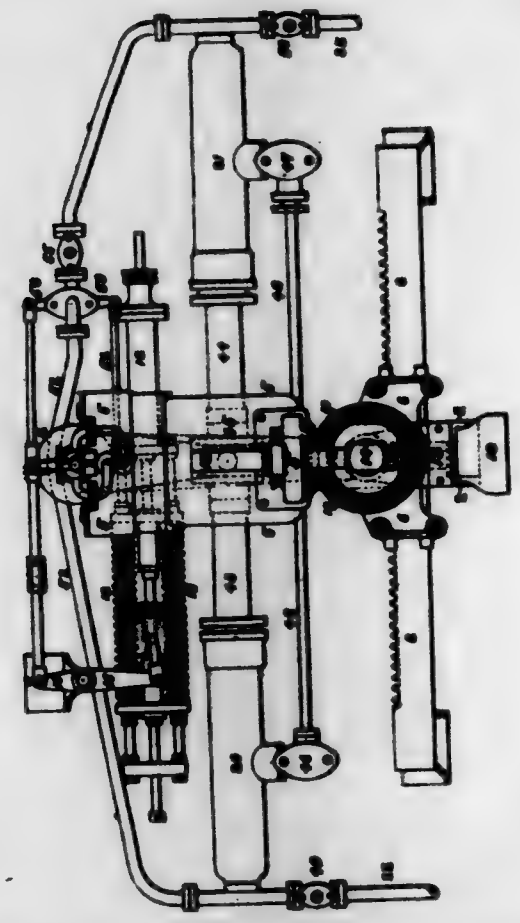
3. A keyhole closing or obscuring device, comprising a plurality of small interengaging square plates arranged in a regularly-divided field, a plurality of sliding plates arranged in such manner that one of them cannot be moved until the next has been moved, and upon each of which sliding plates a plurality of said small square plates are mounted, a spindle passing through each small square plate, a rectangular piece upon the inward end of each spindle, a rectangular space somewhat larger than each rectangular piece in the surface of the back plate around each rectangular piece, a knob attached to the outward end of each spindle in front of the small square plates, and locking devices for the said sliding

plates, said locking devices being adapted to be operated by the limited rotation of certain of said knobs.

4. A keyhole closing or obscuring device, comprising a plurality of small interengaging square plates arranged in a regularly-divided field, a plurality of sliding plates arranged in such manner that one of them cannot be moved until the next has been moved, and upon each of which sliding plates a plurality of said small square plates are mounted, a spindle passing through each small square plate, means for allowing a limited rotation in both directions to each of said spindles, a knob on the outer end of each spindle, lever-arms connected to certain of said spindles behind said small plates, bolts adapted to be operated by said certain spindles, and slots in said sliding plates into which the ends of said bolts are adapted to enter.

5. A keyhole closing or obscuring device, comprising a plurality of small interengaging square plates arranged in a regularly-divided field, a plurality of sliding plates arranged in such manner that one of them cannot be moved until the next has been moved, and upon each of which sliding plates a plurality of said small square plates are mounted, a spindle passing through each small square plate, means for allowing a limited rotation in both directions to each of said spindles, a knob on the outer end of each spindle, means adapted to be operated by a rotation in one direction of certain of said knobs for locking said sliding plates, and means adapted to be operated by a rotation in the reverse direction of certain other of said knobs for locking said sliding pieces.

707,882. STEERING MACHINERY. ANDREW R. BROWN, Edinburgh, Scotland. Filed Dec. 21, 1901. Serial No. 86,220. (No model.)



Claim.—1. Steering machinery comprising a rudder-head, two tiller-arms, a motor on one of the arms and hydraulic rams secured to the other arm, hydraulic cylinders for the rams, said motor-arm having a slotted end, a carriage in said slotted end, a pinion and shaft carried by said carriage and a rack secured to the deck engaged by the pinion, a shaft actuated by the motor and movable radially on the tiller-arm and gearing connecting said shaft with the pinion-shaft, substantially as described.

2. Steering machinery comprising a rudder-head, two tiller arms, a motor on one of the arms and hydraulic rams secured to the other arm, hydraulic cylinders for the rams, said motor-arm having a slotted end, a carriage in said slotted end, a pinion and shaft carried by said carriage and a rack secured to the deck engaged by the pinion, a shaft actuated by the motor and movable radially on the tiller-arm and gearing connecting said shaft with the pinion-shaft, in combination with a distribution-valve, a pump, a hand-wheel and piping connecting said valve and hydraulic cylinders, substantially as described.

3. Steering machinery comprising a rudder-head, two tiller-arms, a motor on one of the arms and hydraulic rams secured to the other arm, hydraulic cylinders for the rams, said motor-arm having a slotted end, a carriage in said slotted end, a pinion and shaft carried by said carriage and a rack secured to the deck engaged by the pinion, a shaft actuated by the motor and movable radially on the tiller-arm and gearing connecting said shaft with the pinion-shaft, in combination with a distribution-valve, a three-cylinder pump, a hand-wheel, piping from the valve to the hydraulic cylinders, stop-valves in said pipes, a valve for the motor, piping connecting the two hydraulic cylinders, a valve in said piping and means to control both the motor-valve and the cylinder-valve together so that they open and close simultaneously, as and for the purpose described.

4. Steering-gear, comprising a rudder-head, a rack on the deck, a tiller-arm, a motor mounted on the arm, a pinion carried by the arm and meshing with the rack and gearing between the motor and the pinion, a second tiller-arm extending from the rudder-head toward the rack but of less length than the first tiller-arm and a hand-wheel and means connecting the wheel and said second arm by which it is operated, substantially as described.

5. Steering-gear, comprising a rudder-head, a tiller-arm, a rack on the deck, a motor on the arm, a pinion on the arm meshing with the rack and gearing between the motor and pinion, a valve to control the motor, hydraulic rams and cylinders secured to the tiller-arm, a valve and piping connecting the cylinders and means for operating the motor-valve and cylinder-valve, simultaneously, substantially as described.

6. Steering-gear, comprising a rudder-head, a tiller-arm, a rack on the deck, a steam-engine on said arm, a radially-movable shaft on said arm adapted to be rotated by the engine, a pinion meshing with the rack, a carriage carried by the arm and gearing between the pinion and radially-movable shaft, and a steam-valve, substantially as described.

7. Steering machinery having a rudder-head, a tiller-arm, a swivel-block for the arm and rams secured to the block, hydraulic cylinders for the rams, a distribution-valve, pump and piping connected with the cylinders and a second tiller-arm and a motor to operate it, substantially as described.

8. Steering machinery having a rudder-head, a tiller-arm, a swivel-block for the arm, and rams secured to the block, hydraulic cylinders for the rams, a three-cylinder pump and a distribution-valve and piping connected with the hydraulic cylinders, a second tiller-arm and a motor to normally operate the rudder-head through such second arm, substantially as described.

9. Steam-steering machinery, comprising a rudder-head and a tiller-arm, a steam-engine and a valve, two hydraulic cylinders, and rams, connected to the tiller, piping connecting the cylinders, a valve in the piping, and a connection between the steam-valve and the valve in the piping whereby they are opened or closed together, substantially as described.

10. Steering machinery, comprising a rudder-head and a tiller-arm, hydraulic cylinders and rams connected to the tiller-arm, in combination with three single-acting pumps, a circular distribution-valve, piping from the pumps to the valve and piping from the valve to the hydraulic cylinders, a hand steering-wheel, a shaft therefor, eccentrics on the shaft, as and for the purpose described.

707,888. ELECTRIC-ARC LAMP. CLIFTON L. BUNDY, Philadelphia, Pa., assignor to himself and Albert H. Mauwering, Philadelphia Pa., copartnership, trading as Philadelphia Electrical and Manufacturing Company. Filed Feb. 12, 1902. Serial No. 93,702. (No model.)

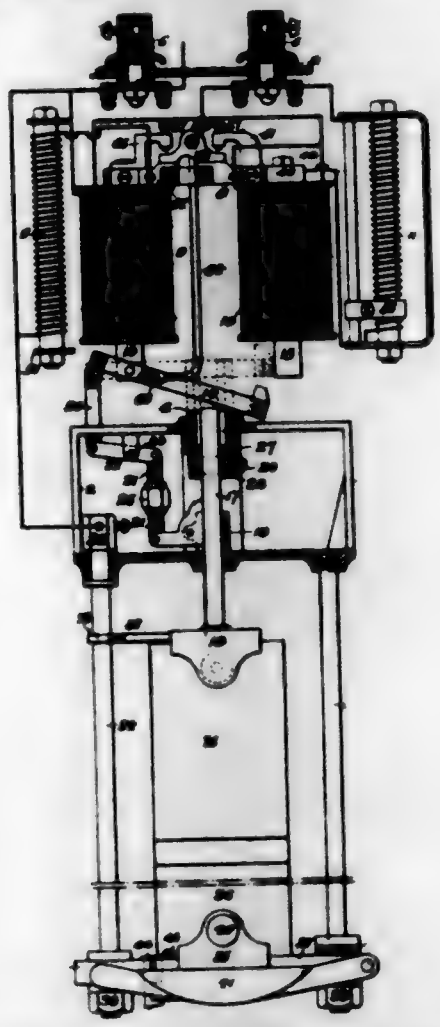
Claim.—1. The combination in an arc-lamp, of the carbons, a vertically-movable rod, a connection between said rod and the upper carbon magnets, an armature pivotally connected to the core of one of said magnets, said armature arranged to rise when the magnets are energized, and a clutch between said armature and the vertically-movable rod whereby the movement of the upper carbon may be varied to strike the proper arc, said clutch consisting of a split collar surrounding the vertically-movable rod, and a pivoted member carried by said collar and adapted to engage the rod, said member being connected to the armature and engaging said rod when the armature is moved.

2. In an arc-lamp of the character described, the combination of the magnets supported at one end by connections entering their cores, and means for varying the voltage of the arc, said means serving to vary the distance between the cores of the magnets at the free ends of the same.

3. In an arc-lamp of the character described, the combination of the magnets supported at the top by connections entering their cores, and means for varying the voltage of the arc, said means consisting of adjusting devices carried by the lower ends of the magnet-cores and serving to vary the distance between the cores at the free ends of the same.

4. The combination in an arc-lamp, of the frame, magnets secured thereto by connections entering the cores of the same, a centrally-depending member, and adjusting-screws passing through the cores of said magnets at their lower ends and bearing upon said depending member, said cores serving to vary the distance between the cores of the magnets at their lower ends only thereby varying the voltage of the arc.

5. In an arc-lamp, the combination of the carbons, a fixed support for the lower carbon, an adjustable support for the upper carbon, a carbon-rod attached to said adjustable support, magnets, an armature pivotally mounted on the core of one of said magnets and movable from and toward the other magnet, and a clutch connection provided with an adjusting-nut arranged between said armature and the carbon-rod, said clutch consisting of a split collar surrounding the vertically-movable rod, and a pivoted member carried by said collar and adapted to engage the rod, said member being connected to the armature, and engaging said rod when the armature is moved.



6. The combination in an arc-lamp, of the carbon-holding frame, a clamping-support for the lower carbon secured to said frame, and binding-screws carried by said support for securing the carbon therein, said holder having tapered inner walls whereby the carbon carried thereby may be adjusted by said binding-screws with relation to the other carbon.

7. The combination in an arc-lamp, of the carbons, a frame in which said carbons are supported, a holder for the upper carbon, a binding-screw carried thereby for securing the carbon therein, said holder being vertically movable, side rods connecting the carbon-holding frame together, and a guide piece or arm carried by the upper-carbon holder and having a forked end engaging one of said rods.

8. The combination in an arc-lamp, of the magnets, an armature, cut-out contacts carried by the lamp-frame and properly insulated therefrom, a shoe for engaging said contacts and a connection passing through the magnet-holding frame and pivotally connected to the shoe and the armature, whereby said shoe may be actuated by the armature to short-circuit the lamp.

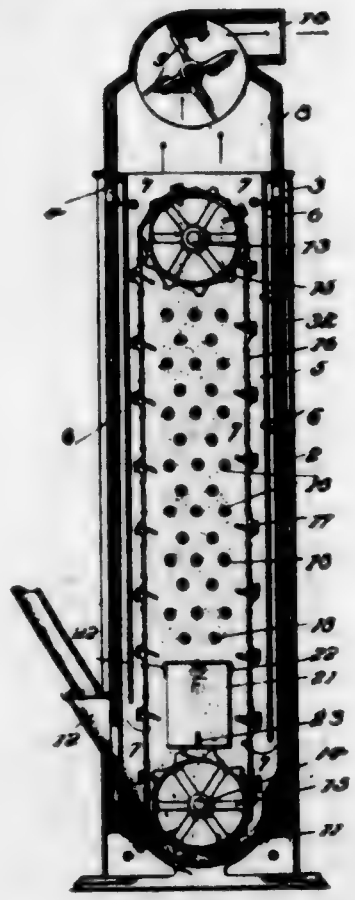
9. The combination in an arc-lamp, of the magnets, an armature, cut-out contacts carried by the lamp-frame and insulated from the magnets, a shoe adapted to engage said cut-out contacts to short-circuit the lamp, a vertically-movable connection between said armature and the shoe, said connection being pivotally mounted on said members, and adjustable engaging means carried by said cut-out contacts.

10. The combination in an arc-lamp, of the frame, magnets carried thereby, an armature, cut-out contacts carried by the lamp-frame, a short-circuiting member adapted to engage said cut-out contacts, a vertically-moving pivotal connection between said member and the armature whereby said member is positively moved as the armature rises and falls, a coil of fixed resistance, and a coil of adjustable resistance arranged in the lamp-circuit, substantially as and for the purpose set forth.

11. The combination in an arc-lamp, of the carbons, magnets, connections between said carbons and magnets, resistance-coils carried by the lamp-frame, auxiliary brackets in which said coils are mounted, a movable contact carried by one of said coils whereby a shunt-circuit may be established around the main magnets, a rod carried by the auxiliary frames to which said movable contact is adapted, and means for adjusting said contact on its supporting-rod.

12. The combination in an arc-lamp of the character described, of the carbon-holding frame, a support for the lower-carbon holder, a dust-pan hinged to one side of said support and at the outside of the carbon-holding frame, and a spring-catch carried by the opposite side of said support for holding the dust-pan in position, said dust-pan having forked ends which pass on either side of the carbon-holding frame.

707,884. HOMINY, MEAL, AND GRITS DRIER. WILLIAM L. BURRER, Columbus, Ohio, assignor to the Case Manufacturing Company, Columbus, Ohio, a Corporation of Ohio. Filed May 24, 1901. Serial No. 61,734. (No model.)



Claim.—1. In a grain-drier, the combination of the outer shell having air-inlet openings, a depending shell within and spaced apart from the outer shell and forming air-passages on two sides of the machine, said inner shell so constructed as to permit said passages to communicate at their lower ends with the drying-chamber for heating the grain, said shells forming a casing for said drying-chamber, and means for dropping the grain in the upper portion of the drying-chamber to permit it to gravitate therein, substantially as set forth.

2. In a grain-drier, the combination of the outer shell 2 having openings 3 and 4, the inner metallic shell 5 forming with said outer shell air-passages and terminating short of the bottom of the machine to bring the passages into communication with the drying-chamber 7, said shells forming a casing for said drying-chamber, means for elevating and dropping material within the drying-chamber, the heating-pipes 18 within the drying-chamber, and means for delivering and discharging material from the machine.

3. In a grain-drier, the combination of the outer shell having air-inlet openings, a depending shell within and spaced apart from the outer shell and forming air-passages on two sides of the machine, said inner shell so constructed as to permit said passages to communicate at their lower ends with the drying-chamber for heating the grain, said shells forming a casing for said drying-chamber, of shafts extending longitudinally through said drying-chamber and carrying sprocket-wheels, chains traveling on the sprocket-wheels, elevator-buckets extending the length of the drying-chamber and mounted on said chains, and a coil of heating-pipes for drying material as it gravitates from the point of discharge of the elevator-buckets, substantially as set forth.

4. In a grain-drier, the combination of the outer shell having air-inlet openings, a depending shell within and spaced apart from the outer shell and forming air-passages on two sides of the machine, said inner shell so constructed as to permit said passages to communicate at their

lower ends with the drying-chamber for heating the grain, said shells forming a casing for said drying-chamber, of shafts extending longitudinally through the drying-chamber and carrying sprocket-wheels, chains mounted upon the sprocket-wheels, elevator-buckets extending the length of the machine mounted upon the chains and a coil of heating-pipes extending longitudinally the machine in the path of the gravitating material which is elevated and discharged by the buckets, substantially as set forth.

5. In a grain-drier, the combination of the outer shell having air-inlet openings, a depending shell within and spaced apart therefrom and forming air-passages on two sides of the machine, said inner shell so constructed as to permit said passages to communicate at their lower ends with the drying-chamber for heating the grain, said shells forming the drying-chamber, sprocket-wheels suitably mounted to rotate in the upper and lower portions of said drying-chamber, chains traveling upon the sprocket-wheels, elevator-buckets mounted upon the chains elevating the material from the bottom of the machine and dropping it at the top, so that it is permitted to gravitate through the drying-chamber, a coil of heating-pipes for drying the grain as it gravitates, and a series of cant-boards by which the material is caused to progress through the machine as it repeatedly gravitates, for the purpose set forth.

6. In a grain-drier, the combination of the outer shell having air-inlet openings, a depending shell within and spaced apart therefrom and forming air-passages on two sides of the machine, said inner shell so constructed as to permit said passages to communicate at their lower ends with the drying-chamber for heating the grain, said shells forming the drying-chamber, elevator-buckets suitably mounted within the drying-chamber and extending the length thereof, a coil of heating-pipes grouped in the path of gravitating material which is elevated and discharged by the buckets, cant-boards located beneath the group of heating-pipes, an inlet-spout at one end of the machine and a tailing-spout at the other end of the machine.

7. In a drier, the combination of the casing formed of an outer non-conducting or wooden shell 2, and an inner metallic heat-conducting shell 5 forming with the outer shell a passage 6, which communicates at its upper end with the outer atmosphere, and at its lower end with the drying-chamber of the machine, said shells forming a casing for said drying-chamber, a hood 8 provided with a fan 9 above the machine for setting up a circulation of air downward through the passage 6 and upward through the drying-chamber, the endless-chain elevator having buckets extending the length of the drying-chamber continually raising and dropping material therein, the group of longitudinal heating-pipes extending through the drying-chamber grouped in the path of the gravitating material discharged by the elevator-buckets, the intake-spout at one end of the machine, the tailing-spout at the other end of the machine, a series of cant-boards 21 located in the path of the gravitating material, an incline 25 at the tailing end of the machine and directing material to the tailing-outlet, substantially as set forth.

8. In a grain-drier, the combination of a suitable drying-chamber and means for elevating and precipitating grain into said drying-chamber, said means comprising suitably-arranged sprocket-wheels, chains carried by said wheels, said chains having solid links interposed at suitable intervals therein and buckets carried by said chains comprising slotted angle-bars, said slots adapted to receive said chains whereby said buckets are capable of being rivoted to said solid links.

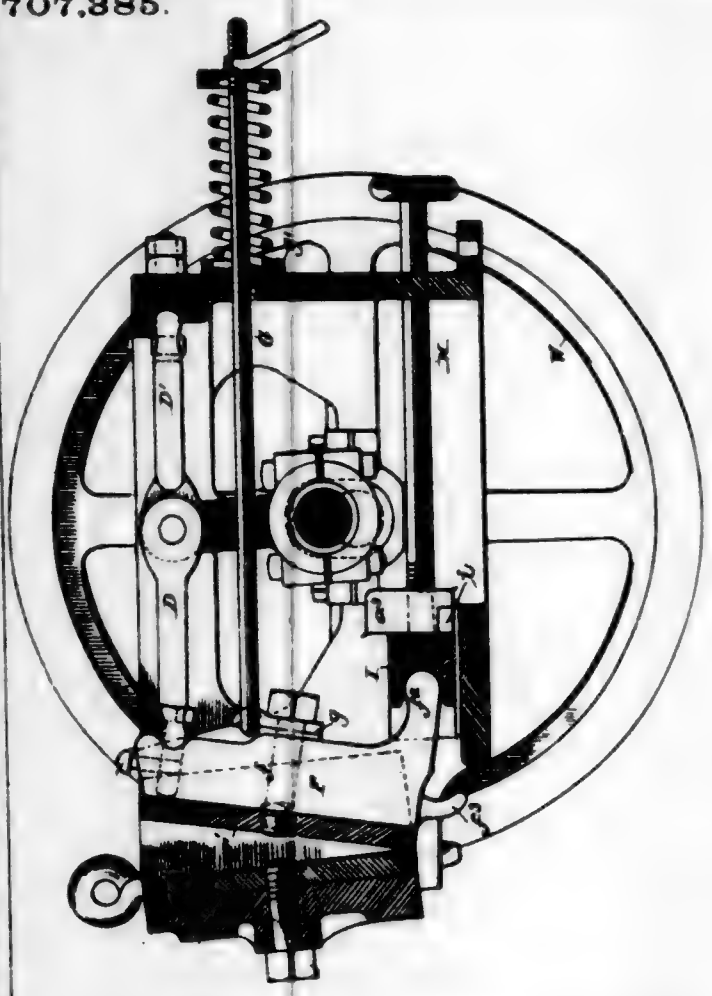
707,885. ORE-BREAKER. ALBERT C. CALKINS, Los Angeles, Cal., assignor to Frederick W. Braun, Los Angeles, Cal. Filed June 8, 1901. Serial No. 63,732. (No model.)

Claim.—1. In an ore-crusher, the combination with an inclosing casing open at one end and having perforated lugs at its said open end on each side; of a removable jaw having corresponding perforated lugs adapted to register with the lugs of the casing, and two pins passing through said registering lugs to secure the jaw in place substantially as described.

2. In an ore-crusher, the combination with an inclosing casing open at one end and having perforated lugs at said open end on each side; of a removable jaw having corresponding perforated lugs adapted to register with the lugs of the casing, two pins passing through said registering lugs to secure the jaw in place, and set-screws passing through the jaw and bearing against the casing to take up looseness in the joints between the jaw and casing substantially as shown and described.

3. In an ore-crusher, the combination with the stationary jaw, and the vibratory jaw having a heel at its lower end; of an adjustable heel-block having a fulcrum-cast for the heel of the jaw in front and guide-lugs in the rear, a main frame or casing having on each side an inwardly-projecting lug arranged behind the heel-block and having a screw-threaded hole through it, and an adjusting screw on each side tapped through said lug and bearing against the heel-block and extending outside of the casing and provided with a handle, substantially as described.

707,885.



707,886. COUPLING FOR PITMEN. JOHN R. CARTER, Augusta, Ky., assignor to Ernst H. Huenefeld, Cincinnati, Ohio. Filed Apr. 19, 1902. Serial No. 103,815. (No model.)

Claim.—1. The combination of two hooks to be locked on a shaft, and means on the side face of one hook between the outer and inner edges thereof to engage the adjacent side of the other hook and lock the hooks together.

2. The combination of two hooks to be locked on a shaft, a lug on the side face of one hook and the other hook channeled on one face to receive this lug and lock the hooks against removal from the shaft when turned out of their position for assembling.

3. The combination of two hooks to be locked on a shaft, a lug on the side face of one of the hooks and the other hook having a channel and an entrance to said channel for the lug to lock the hooks together when the lug is moved into the channel and away from the entrance.

4. The combination with a single hook and double hooks to be locked upon a shaft, the single hook having a channel on one side, of a lug on the inner face of one of the double hooks to enter the channel and lock the hooks together when either is turned.

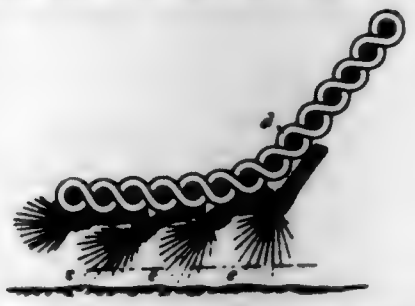
5. The combination of double hooks and a single hook to be locked upon a shaft, there being channels in the side faces of the single hook having entrances to said channels at the base of the hook and lugs or segments on the inner faces of the double hooks at the base portions thereof to enter the channels in the single hook through said entrances and move into the channels when either hook is turned out of its position for assembling.

707,887. SKIRT-PROTECTOR. JOSEF CATHREIN, Munich, Germany, assignor to Ignaz Friedinger, Oberthal, near Linz, Austria-Hungary. Filed Apr. 28, 1902. Serial No. 105,112. (No model.)

Claim.—1. A skirt-protector consisting of a series of rows of overlapping brush-like braid secured to the under side of the skirt and having the bristles projecting rearwardly and downwardly.

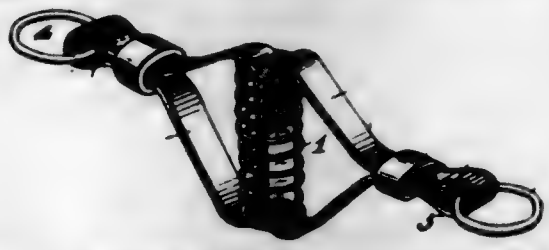
2. A skirt-protector consisting of a series of rows of brushes secured to the under side of the skirt, the bristles of each row overlapping the ad-

jacent row and projecting in the general direction of the edge of the skirt at less than a right angle to the skirt-body at the point of attachment.



3. A skirt-protector consisting of a series of overlapping rows of brush-like fabric secured to the under side of the skirt and extending for an appreciable distance upward from the bottom edge thereof, so arranged that the bristles will lie approximately parallel with the skirt and project toward the edge of the skirt.

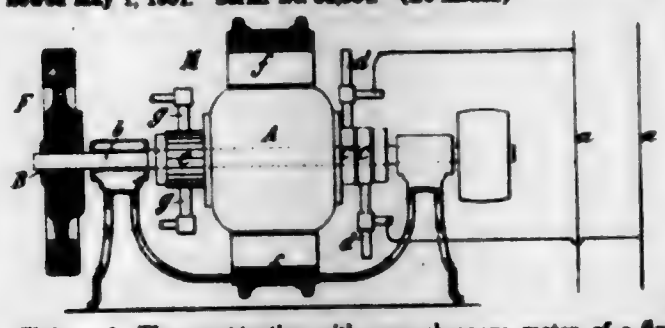
707,888. ELASTIC CONNECTION FOR CHECKREINS. JOHN M. CHAPPIE, Redcloud, Neb. Filed Mar. 4, 1902. Serial No. 96,602. (No model.)



Claim.—1. In a checkrein device, the combination of a coiled spring, two loops engaging said spring, and means for attaching each of said loops to a checkrein, said means being arranged to exert a pull on the loops at right angles to the longitudinal axis of said spring, substantially as described.

2. In a checkrein device, the combination of a coiled spring, two loops engaging said spring, reins engaged by said loops and arranged so that the pull thereon will be at right angles to the axis of the spring, substantially as described.

707,889. SYNCHRONOUS ALTERNATING-CURRENT MOTOR. ALEXANDER CHURCHWARD, Fort Wayne, Ind. Filed Oct. 1, 1898. Renewed May 1, 1901. Serial No. 58,264. (No model.)



Claim.—1. The combination with a synchronous motor of a fly-wheel driven thereby through the medium of a yielding connection for producing the effect described.

2. The combination with a synchronous motor of a fly-wheel mounted on its shaft and driven thereby through the medium of a yielding connection.

3. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving-shaft, and a yielding connection between such fly-wheel and the motor, for producing the effect described.

4. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving-shaft, and springs interposed between the fly-wheel and shaft for producing the effect described.

5. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving-shaft, a collar fixed to said shaft, and springs constituting a yielding connection between the fly-wheel and collar.

6. The combination with a synchronous motor of a fly-wheel driven thereby free to turn on its driving-shaft, a collar fixed to said shaft, springs constituting a yielding connection between the fly-wheel and collar, and a stop to limit the strain on said springs.

7. The combination with a synchronous motor of a fly-wheel F driven thereby, a collar C fixed on the driving-shaft and having projections A A, and springs S S interposed between said projections and the fly-wheel.

8. The combination with a synchronous motor of a fly-wheel F driven thereby having arc-shaped chambers *i i*, a collar C fixed on the driving-shaft and having projections A A projecting into said chambers, and springs S S interposed between said projections and the fly-wheel and inclosed in said chambers.

9. The combination with a synchronous motor of a fly-wheel F driven thereby, a collar C fixed on the driving-shaft and having projections A A, and springs S S interposed between said projections and the fly-wheel, and said fly-wheel and collar formed with mutually-abutting stops to limit the compression of said springs.

10. A synchronous motor and a load tending to maintain speed independently of the motor and coupled therewith by a yielding connection.

11. A synchronous motor and a load therefor tending to maintain speed independently of the motor and provided with means for affording a yielding engagement between the same and the said machine.

12. In a system of electrical distribution, the combination with a generator of alternating currents, of a motor supplied with current from the generator, a load for the motor tending to maintain speed independently of the motor, and means whereby the said load is yieldingly connected with the motor, substantially as described.

13. In a system of electrical distribution, the combination with a generator of alternating currents, of a motor supplied with current from the generator, a load for the motor tending to maintain speed independently of the motor, and spring mechanism whereby said load is yieldingly connected with the motor, substantially as described.

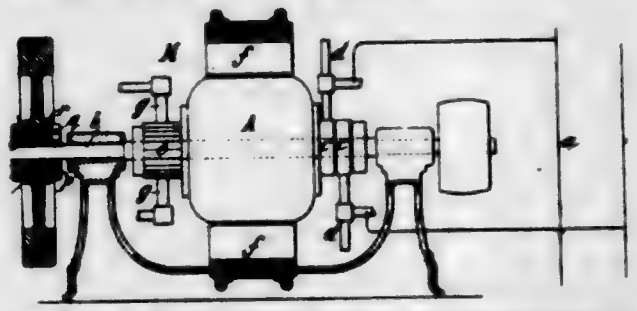
14. The combination with a synchronous dynamo-electric machine, of a fly-wheel driven thereby through the medium of a yielding connection, for producing the effect described.

15. The combination with a synchronous dynamo-electric machine, of a load operated thereby through the medium of a yielding connection, said load tending to maintain speed independently of the dynamo.

16. The combination with a rotary conveyer, of a fly-wheel driven thereby through the medium of a yielding connection for producing the effect described.

17. The combination with a rotary converter, of a load operated thereby through the medium of a yielding connection, said load tending to maintain speed independently of the converter.

707,890. SYNCHRONOUS ALTERNATING-CURRENT MOTOR. ALEXANDER CHURCHWARD, Fort Wayne, Ind. Filed Jan. 11, 1899. Renewed Feb. 21, 1901. Serial No. 48,279. (No model.)



Claim.—1. The combination with a synchronous motor of a fly-wheel driven thereby through the medium of a yielding frictional connection for producing the effect described.

2. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving-shaft, and a yielding frictional connection between such fly-wheel and the motor, for producing the effect described.

3. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving shaft, and connected thereto by means of an adjustable friction-brake.

4. The combination with a synchronous motor of a fly-wheel driven thereby, free to turn on its driving-shaft, and a yielding frictional connection between said fly-wheel and its shaft consisting of friction-plates and springs pressing said plates together.

5. The combination with a synchronous dynamo-electric machine, of a fly-wheel driven thereby through the medium of a yielding frictional connection for producing the effect described.

6. The combination with a synchronous dynamo-electric machine, of a load operated thereby through the medium of a yielding frictional connection and tending to maintain speed independently of the dynamo.

7. The combination with a rotary converter, of a fly-wheel driven thereby through the medium of a yielding frictional connection for producing the effect described.

8. The combination with a rotary converter, of a load operated thereby through the medium of a yielding frictional connection, said load tending to maintain speed independently of the converter.

707,891. WRENCH. ROBERT J. CUMMINGS, Leadville, Colo., assignor of one-half to Leonard M. Smith, Leadville, Colo. Filed Mar. 28, 1902. Serial No. 100,544. (No model.)

Claim.—1. The combination with a lever-bar having a fixed jaw on one end, of a loose jaw, a wedge-block held to slide on the lever-bar and pivoted near one end upon an extension of the loose jaw, and means for holding the wedge block releasably clamped upon the lever-bar.

2. The combination with a lever-bar having a fixed jaw on one end, of a loose jaw having an extension rockable in a slot in the lever-bar, a wedge-block held to slide on the lever-bar and pivoted near one end upon the extension of the loose jaw, and means for releasably clamping the wedge-block upon the lever-bar.

3. The combination with a lever-bar having a convex-faced jaw on one end, and a loose jaw rockable in a slot in the lever-bar and having a concave face, of a slotted wedge-block bearing upon the lower edge of the lever-bar, a clamping-block having members engaging the lever-bar, and a screw-bolt passing through the clamping-block and slot in the wedge-block, its inner end screwing into the lever-bar.

4. The combination with a lever-bar having a convex-faced jaw on one end, and a loose jaw rockable in a slot in the lever-bar and having a concave face, of a slotted wedge-block, a fulcrum-box on one end of the wedge-block wherein one end of the convex-faced jaw is pivoted, and a clamping-block the top face of which is inclined oppositely from the inclined surface of the wedge-block upon which it bears, and a screw-bolt passing through the clamping-block and through the slot in the wedge-block and having screwed engagement with the lever-bar.

5. In a wrench of the character described, the combination with the lever-bar having a fixed jaw on one end, and a mating rockable jaw, of a wedge-block slidable on an edge of the lever-bar and having a longitudinal slot therein, one end of the wedge-block being pivoted upon a depending end of the rockable jaw, and a clamping-block having two spaced studs passing loosely through the slot in the wedge-block and entering sockets in the lever-bar, and a screw-bolt having a winged head, the threaded body of said bolt passing loosely through the clamping-block and the slot in the wedge-block, its inner end screwing into a tapped hole in the lever-bar.

6. In a wrench of the character described, the combination with the lever-bar, and a fixed jaw and a rockable jaw, of a slotted wedge-block, a clamping-block having a bearing-face inclined oppositely to the inclined face of the wedge-block upon which it bears, studs on the clamping-block, holding the wedge-block and said clamping-block from lateral displacement on the lever-bar, and a screw-bolt passing through the clamping-block and wedge-block into the lever-bar.

707,892. MACHINE FOR TRIMMING CURLED HAT-BRIMS.

FRANK C. CRAW, South Norwalk, Conn., assignor of one-half to Willis R. Austin and William H. Craw, doing business under firm-name of Austin and Craw, South Norwalk, Conn. Filed Apr. 19, 1900. Serial No. 13,457. (No model.)

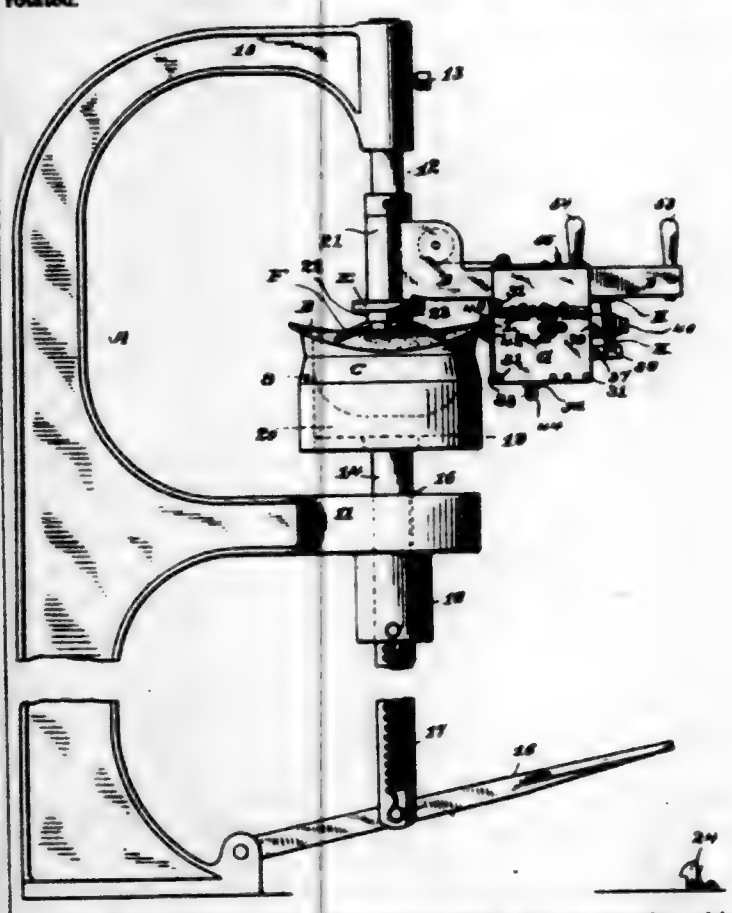
Claim.—1. In a machine of the character described, the combination with a curling-block carrier having a recess to receive the crown of a hat and also having means for connecting a hat-curling block therewith with the hat-crown in said recess, of a cutter, an element by which said cutter is carried and with reference to which the cutter has oscillatory movement, and mechanism whereby said cutter is moved vertically and longitudinally to conform to the curvature of the brim.

2. In a machine of the character described the combination with a curling-block carrier and means for holding a curled hat rigidly while on a curling-block and with the crown downward, of a cutter acting from below the brim and means for causing said cutter to act in a plane tangential to the curve of the brim.

3. In a machine of the character described the combination with means for holding a curled hat with the crown downward, of a cutter acting from below the brim and mechanism whereby said cutter is moved vertically and longitudinally to conform to the curvature of the brim.

4. In a machine of the character described the combination with means for holding a curled hat, of a rotating arm, a longitudinally-moving head on said arm, a longitudinally-moving block J within the head, a vertically-moving block M carried by block J and an oscillating cutter carried by block M.

5. In a machine of the character described the combination with a longitudinally-movable head, a block J longitudinally movable within the head, a block M vertically movable in block J and an oscillating cutter carried by block M, of a carrier for a curled hat, and an arm by which the head is carried and means whereby one of said parts may be rotated.



6. In a machine of the character described the combination with means for holding a curled hat and a bevel gear-wheel E, of arm D, a head longitudinally movable on said arm and carrying a shaft with a bevel gear-wheel engaging gear-wheel E, a block J within the head, connections intermediate the shaft and the block whereby the latter is moved longitudinally independently of the head, a block M vertically movable in block J and an oscillating cutter carried by block M.

7. In a machine of the character described the combination with means for holding a curled hat and a bevel gear-wheel E, of arm D, a head longitudinally movable on said arm, a shaft journaled in said arm and carrying a bevel-pinion engaging the gear-wheel, pinion H having a groove 29, said pinion being carried by the shaft but free to slide thereon and said head having a lug engaging the groove, a block J within the head, an arm extending from said block and having a groove 38, a stud extending from the head, a cam-gear mounted on said stud and engaging the sliding pinion and groove 38, a block M vertically movable in block J and an oscillating cutter carried by block M.

8. In a machine of the character described the combination with means for holding a curled hat, arm D and the sliding head having a front adapted to engage a hat-brim, of a spring for holding the front of the head in engagement with the hat-brim, a block J, block M vertically movable in block J, an oscillating cutter carried by block M, a spring for holding said block up so that the cutter will always engage the brim and means for imparting longitudinal movement to block J independently of the head so that the curl may be given any required width at the ends and sides.

9. In a machine of the character described, the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29, a block J in said head, an arm extending from said block and having a groove 38, a stud extending from the head, a cam-gear mounted on said stud and engaging the sliding pinion and groove 38 whereby longitudinal movement is imparted to block J independently of the head, a vertically-movable block M in block J and an oscillating cutter carried by block M.

10. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29, a spring for moving said head forward on the arm, means for locking said head in the retracted position against the power of the spring, a block J in said head, an arm extending from said block and having a groove 38, a stud extending from the head, a cam-gear mounted on said stud and engaging the sliding pinion and groove 38, a vertically-movable block M in block J and an oscillating cutter carried by block M.

11. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29, a block J in said head, connections intermediate block J and the sliding pinion whereby said block is moved longitudinally independently of the head, a vertically-movable block M in block J, an oscillating cutter carried by block M, a spring for holding block M and the cutter in operative position and means for locking block M in the retracted position against the power of the spring.

12. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29, a spring for moving said head forward on the arm, a block J in said head, connections intermediate block J and the sliding pinion whereby said block is moved longitudinally independently of the head, a vertically-movable block M in block J and an oscillating cutter carried by block M.

13. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29 and a slot 36, a block J in said head having an arm 37 which extends through slot 36 and is provided with a groove 38, a stud extending from the head, a cam-gear mounted on said stud and engaging the sliding pinion and groove 38, a vertically-movable block M in block J and an oscillating cutter carried by block M.

14. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29 and a slot 35, a block J in said head, connections intermediate block J and the sliding pinion whereby said block is moved longitudinally independently of the head, a block M lying in block J and extending through said slot, a spring by which block M is held up, an oscillating cutter carried by block M and means for retaining said block and the cutter at a retracted position against the power of the spring.

15. In a machine of the character described the combination with arm D, a shaft journaled therein and a pinion carried by said shaft and adapted to slide thereon and having a groove 29, of a head adapted to slide on said arm and having a lug engaging groove 29 and a slot 34, a block J in said head having a slot 43, connections intermediate block J and the sliding pinion whereby said block is moved longitudinally independently of the head, a vertically-movable block M in block J, said block M having an arm 42 extending through slots 43 and 34 and an oscillating cutter carried by said arm.

16. In a machine of the character described the combination with arm D, a head adapted to slide thereon and a block within the head having an arm extending therefrom with a groove 38, of a shaft journaled in the arm, a pinion carried by said shaft and free to slide thereon, means for connecting the sliding pinion to the head so that the head will move the pinion on the shaft, a stud extending from the head and a cam-gear mounted on the stud and engaging the sliding gear and groove 38 whereby the block is moved longitudinally independently of the head.

17. In a hat-brim-trimming machine, the combination with the cutter L having a shank 41 and a cutting edge radial to the axis of the said shank, of means for supporting a hat with its brim in position to be trimmed by said cutter.

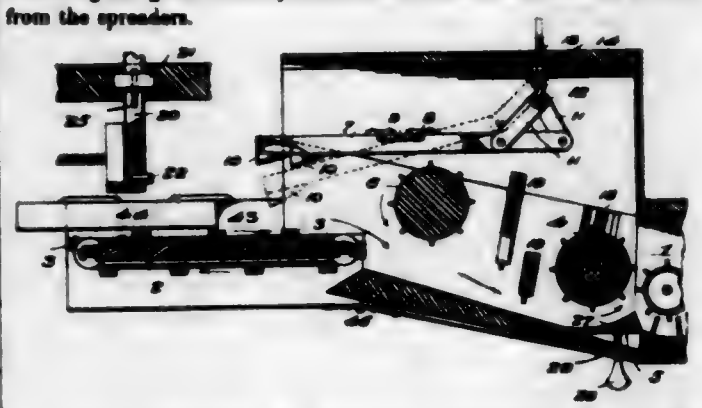
18. In a hat-brim-trimming machine, the combination with the cutter L having a shank 41, a flange 46, and a cutting edge above the flange and extending radial to the axis of the shank, of means for supporting a hat with its brim in position to be trimmed by said cutter.

19. In a machine of the character described the combination with a carrier adapted to receive a hat upon a curling-block, a holder F and means for pressing the hat against the holder, of arm D, the sliding head, sliding block J within the head, sliding block M within block J and an oscillating cutter carried by block M.

20. In a machine of the character described the combination with a carrier adapted to receive a hat upon a curling-block, a holder F, means for pressing the hat against the holder and means for lowering the carrier against the power of the spring and for locking the carrier out of operative position, of arm D, the sliding head, sliding block J within the head, sliding block M within block J and an oscillating cutter carried by block M.

707,898. BAND-CUTTER AND FEEDER. WILLIAM E. CROW, Cromwell, Ind. Filed Oct. 28, 1901. Serial No. 80,248. (No model.)

Claim.—1. In a band-cutter and feeder and in combination, a closure-frame, an endless-platform feeder, means for cutting the sheaf-bands, a pair of spreader-arms, a pair of hangers, one for each spreader-arm in the opposite walls of the frame, a crank-shaft connecting the outer end of each spreader, at the opposite sides of the closure, means for operating each crank-shaft, for causing each spreader to have opposite inward and outward movement upon their hangers, the outward movement of one alternating with the inward movement of the other, a toothed roll delivering the grain to the spreaders and a toothed roll drawing the grain from the spreaders.



2. In a band-cutter and feeder, the combination with an endless-platform feeder and sheaf-band cutters, of a pair of grain-spreading arms, each mounted in the opposite sides of the frame in parallel lapping relation to each other, means for causing each spreader to have a horizontal movement in opposite directions, a toothed feed-roll between the delivering end of the platform-feeder and the spreaders and a toothed feed-roll at the rear of the spreaders the two spreader-arms evening the grain alike from the center to the sides.

3. In a band-cutter and feeder, and in combination, an endless-platform feeder, band-cutting arms, a pair of toothed feed-rolls, a pair of spreader-arms, each arm separately fulcrumed in the opposite sides of the closure, a crank-shaft separately connecting the outer end of each spreader-arm at the opposite sides of the closure, gear 40 41 separately connecting each crank-shaft, with the feed-roll 6, a belt 33 connecting the pair of feed-rolls and the power-driven pulley 42 on the shaft of the feed-roll at the delivery end of the closure.

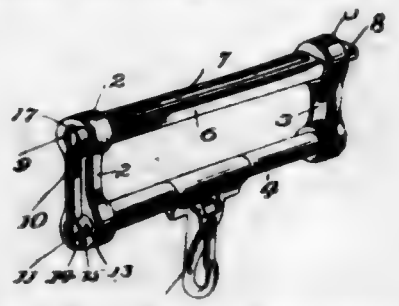
4. In a band-cutter and feeder and in combination, an endless-platform feeder, a downwardly-inclined fixed bottom supplemented by a sheet-metal surface terminating at its delivering end in a raised curved part, a toothed roll at the end of said fixed bottom and screws in the fixed bottom engaging the sheet-metal part to adjust it in relation to the roll.

5. In a band-cutter and feeder and in combination, a closure-frame, an endless slatted traveling platform, cutters for severing the sheaf-bands, a toothed roll at the delivering end of the closure, a fixed bottom having a smooth surface extending from the traveling platform and terminating in an integral upward-curved part, and means for adjusting said integral bottom part in its relation to the teeth of the roll.

6. In a band-cutter and feeder and in combination, an endless-platform feeder, a downwardly-inclined fixed feed-bottom having a smooth surface and terminating in a raised curved end, a toothed feed-roll arranged to pull the grain over said raised curved end, a toothed spreader-arm supported in each side of the closure, and means separately connecting and operating each spreader-arm to cause it to spread and even the grain from the center toward the sides of the closure as the grain is moved to said roll.

7. In a band-cutter and feeder and in combination with a closure-frame, an endless-platform feeder, band-cutters and a feed-roll at the delivering end of the platform-feeder, a pair of spreader-arms passing through each side of the closure, a pair of hangers one for each spreader-arm secured in the wall-opening through which the arm passes, means for vertically adjusting the fulcra of the hangers, and means whereby the spreader-arms are reciprocated and vertically rocked upon their respective hangers toward and from each other.

707,894. BACK-BAND BUCKLE. ELI H. CRUM, Cloverbend, Ark. Filed May 24, 1901. Serial No. 61,763. (No model.)



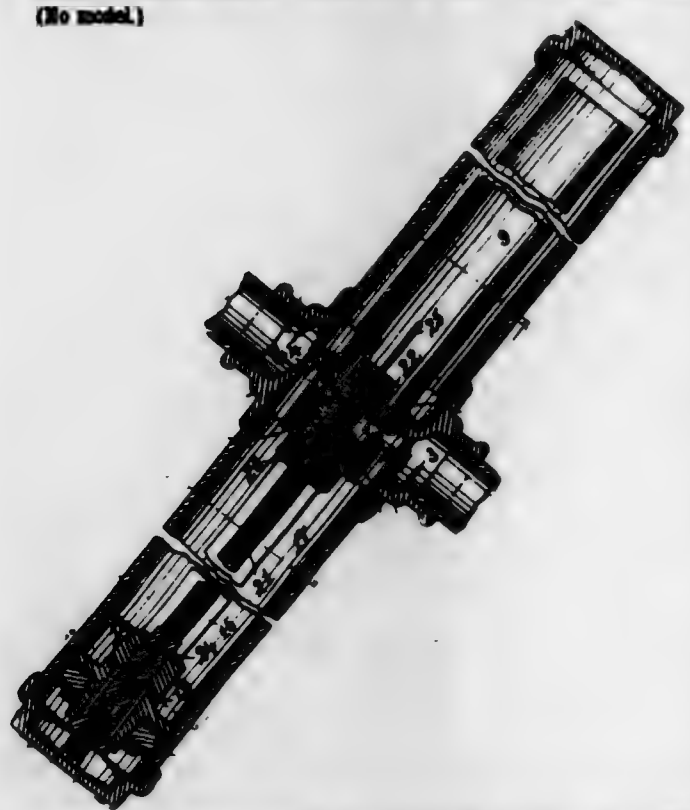
Claim.—1. The herein-described back-band attachment comprising the frame members 2, 3 and 4 rigidly secured together, a slotted mem-

ber 6 rotatably mounted in the end members of said frame; an extension 9 formed on the end of said rotatable member and provided with a recess in its end, combined with an outwardly-movable detent adapted to engage said recess and means to normally hold the detent in place whereby when said detent is withdrawn the rotatable member 6 may be turned to release or tighten the back-band, all substantially as specified and for the purpose set forth.

2. The herein-described back-band attachment comprising the end sections 2 and 3, and the member 4 rigidly connecting said end sections combined with the member 6 having the longitudinally-disposed slot rotatably mounted in said end sections and provided at one end with a handle portion 8 and at the opposite end with the recessed extension 9, and a spring-controlled detent normally held in engagement therewith whereby the upper end of said detent will rest in the recess provided in the extension 9 and may be manually withdrawn therefrom as desired, all substantially as specified and for the purpose set forth.

3. A back-band attachment comprising a suitable frame-section combined with a slotted rotatable member 6, carried in the frame and having an operating-handle at one end extending outward from the frame and provided with the extension 9 upon the opposite end said extension 9 being provided with a recess in its extreme end, and a detent pivoted upon the outer side of the frame and having its free end extending into said recess combined with a suitable spring to hold the free end of the detent normally inward whereby the slotted rotatable member 6 may be adjustably secured by means of said handle and said coöperating detent, all combined substantially as specified and for the purpose set forth.

707,895. AUTOMATIC VALVE. HELMER CURTIS, Boston, Mass., assignor to the Sumner & Goodwin Company, Boston, Mass., a Corporation of Massachusetts. Filed Oct. 26, 1900. Serial No. 34,497. (No model.)



Claim.—1. In an automatic valve, a casing having inlet and outlet openings, a cylindrical chamber at each end of said casing, said chambers being of different cross-sectional areas, pistons in said chambers, coupled together so as to move in unison, a chamber intermediate the pistons, the smaller end chamber in open communication with the inlet-opening, the intermediate chamber in open communication with the outlet-opening, ports forming communication between the smaller end chamber and intermediate chamber controlled by the movements of the pistons, a cavity and contracted port forming a discharge-passage for the larger end chamber, a valve controlling communication between the larger end chamber and said cavity, and a spring to open said valve, for the purpose set forth.

2. In an automatic valve, a casing having inlet and outlet openings, a cylindrical chamber at each end of said casing said chambers being of different cross-sectional areas, pistons one in each of said chambers coupled together so as to move in unison, a chamber intermediate the pistons, the smaller end chamber in open communication with the inlet-opening, the intermediate chamber in open communication with the outlet-openings, ports forming communication between the smaller end chamber and intermediate chamber controlled by the movements of the pistons, a cavity forming communication between the larger end chamber and intermediate chamber, a valve controlling communication between the larger end chamber and said cavity, and a spring to open said valve, for the purpose set forth.

3. In an automatic valve, a casing having inlet and outlet openings, a cylindrical chamber at each end of said casing said chambers being of different cross-sectional areas, pistons one in each of said chambers coupled together so as to move in unison, a chamber intermediate the pistons, the smaller end chamber in open communication with the inlet-opening, the intermediate chamber in open communication with the outlet-opening, communication between the smaller end chamber and intermediate chamber controlled by the movement of the pistons, a cavity and contracted port forming a discharge-passage for the larger end chamber, a valve controlling communication between the larger end chamber and said cavity, and a spring to open said valve, for the purpose set forth.

4. In an automatic flushing device, a casing having inlet and outlet openings, a chamber at each end of said casing said chambers being of different cross-sectional areas, pistons in said chambers coupled together so as to move in unison, a chamber intermediate the pistons in open communication with the outlet-opening, the smaller end chamber in open communication with the inlet-opening, ports forming communication between the smaller end chamber and the intermediate chamber through which the flushing-water passes, the piston in the smaller end chamber controlling said ports, and means to cause the reciprocation of said pistons in their chambers, for the purpose set forth.

5. In an automatic valve, a casing having inlet and outlet openings, a chamber at each end of said casing said chambers being of different cross-sectional areas, pistons in said chambers coupled together so as to move in unison, a chamber intermediate the pistons in open communication with the outlet-opening, the smaller end chamber in open communication with the inlet-opening, ports forming communication between the smaller end chamber and the intermediate chamber, the piston in the smaller end chamber controlling said communication, a regulating device to regulate the size of said communication, and means to cause the reciprocation of said pistons in their chambers, whereby the amount discharged through the outlet-opening at each operation of the valve is regulated, for the purpose set forth.

6. In an automatic valve, a casing having inlet and outlet openings, a chamber at each end of said casing said chambers being of different cross-sectional areas, a piston in each of said chambers, coupled together so as to move in unison, a chamber intermediate the pistons in open communication with the outlet-opening, the smaller end chamber in open communication with the inlet-opening, ports forming communication between the smaller end chamber and the intermediate chamber, the piston in the smaller end chamber controlling said port, a sleeve having ports therein to control the size of the unobstructed opening through the ports which form communication between the smaller end chamber and the intermediate chamber, and means to cause the reciprocation of said pistons in their chambers, whereby the amount of discharge at each operation of the valve is regulated by the adjustment of said sleeve, for the purpose set forth.

7. In an automatic valve, a casing having inlet and outlet openings, a chamber at each end of said casing said chambers being of different cross-sectional areas, a piston in each of said chambers coupled together so as to move in unison, a chamber intermediate the pistons in open communication with the outlet-opening, the smaller end chamber in open communication with the inlet-opening, communication between the smaller end chamber and the intermediate chamber controlled by the movements of the piston in the smaller end chamber, a port through said pistons forming communication between the two end chambers to cause the movement of said pistons in one direction, a rod within said port movable longitudinally therein to contract said port and to prevent it from clogging, a discharge-passage from the larger end chamber to control the movement of the pistons in the opposite direction, a valve controlling said discharge-passage, and means to operate said valve, for the purpose set forth.

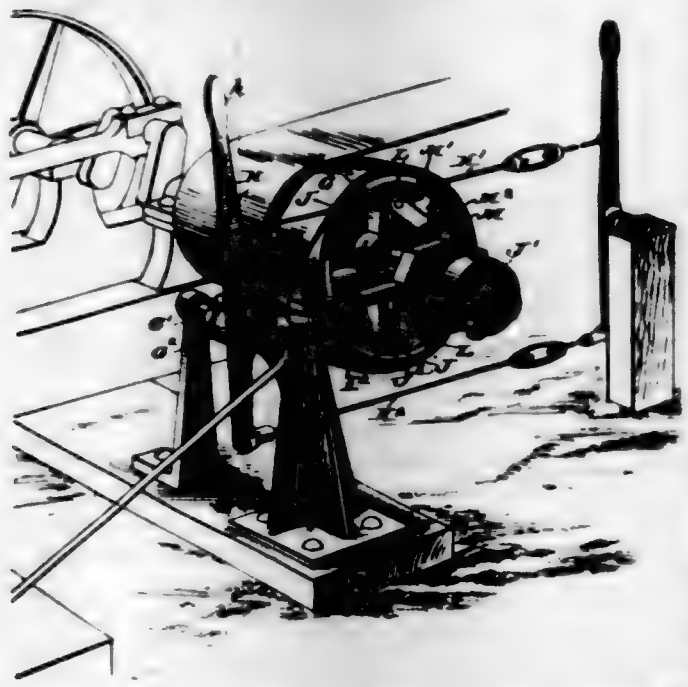
8. In an automatic valve, a casing having inlet and outlet openings, a chamber at each end of said casing said chambers being of different cross-sectional areas, a piston in each of said chambers coupled together so as to move in unison, a chamber intermediate the pistons, a port through said pistons forming communication between the end chambers to cause the movement of said pistons in one direction, an outlet-passage from the larger chamber, a valve controlling said outlet-passage, and means to operate said valve to cause the movement of the pistons in the opposite direction, for the purpose set forth.

9. In an automatic valve, a casing consisting of a central portion having inlet and outlet openings and a partition separating said openings, two tubes attached to said central portion, end caps on said tubes, and a central tube attached within a perforation in and extending on each side of said partition open at its ends, two pistons of different areas coupled together to move in unison, one piston reciprocating in one of the two tubes

attached to said central portion and the other piston reciprocating in said central tube, a chamber formed between the two pistons in open communication with the outlet-opening, ports through the central tube forming communication between said tube and outlet-opening, a sleeve regulating the size of the unobstructed openings through said ports, a cavity in the piston of the greater area and a contracted port forming communication between the two sides of said piston, a valve controlling the entrance to said cavity of increased area over the port from said cavity, a valve-stem for said valve extending through and beyond the opposite piston, a spring on said valve-stem, a port forming communication through the piston and between the chambers on opposite sides thereof, and a rod to contract said port and move longitudinally therein at each end of the movements of the pistons, all combined, for the purpose set forth.

10. In an automatic valve, a casing having inlet and outlet openings, a chamber at each end of said casing and of different cross-sectional areas, pistons coupled together and reciprocating in said chambers, the smaller chamber in open communication with the inlet-opening, communication between the end chambers to cause the reciprocation of the pistons in one direction, a discharge-passage from the larger end chamber, a contracted port in said passage, a valve controlling said passage and of greater area than the contracted port, means operated by the reciprocations of said pistons to open and close said valve, and a spring to open said valve to its fullest extent when raised from its seat by said pistons, for the purpose set forth.

707,396. **REVERSING-PULLEY MECHANISM.** JOSEPH DARLING, Chicora, and CHARLES C. ELLENBERGER, Jr., Peachville, Pa. Filed June 21, 1901. Serial No. 65,448. (No model.)



Claim.—1. An apparatus substantially as described comprising the shaft, a wheel or pulley loose on the shaft and having a gear-ring, a gear-wheel fixed to the shaft, intermediate pinions meshing with and connecting the gears of both the shaft and the pulley, a support for the said pinions, such support being loose on the shaft and provided with a drum, a brake-band encircling the said drum, clutch devices operating within the drum, and a lever connected with and arranged to operate the brake-band, and means whereby the said lever may also operate the clutch devices substantially as set forth.

2. An apparatus substantially as described comprising the shaft, the pulley or wheel thereon and having a gear ring, a gear-wheel on the shaft, intermediate pinions between said gears, a support for said pinions normally loose on the shaft, a drum in connection with said support, a clutch body or carrier, clutch-blocks movable radially therein lever-links pivoted to the clutch-body, and engaged between their ends with the clutch-blocks, the rockers having arms pivotally connected with the outer ends of the lever-links, and the clutch-collar to which said rockers are jointed substantially as set forth.

3. In an apparatus substantially as described the combination with the shaft and the pulley or wheel of gearing between the said pulley and shaft including intermediate pinions, a support for said pinions, a drum in connection with said support, a brake operating upon said drum, clutch devices operating within the drum, a bell-crank lever having one arm connected with the clutch devices, and a second arm for engagement with the operating-lever and the operating-lever engaged with such arm of the bell-crank lever and connected with and arranged to operate the brake substantially as set forth.

4. In an apparatus substantially as described, the combination of the shaft, the wheel or pulley loose on the shaft and having a gear-ring, a gear-ring fixed on the shaft, intermediate pinions meshing with and connecting the gears, a support for said pinions loose on the shaft and provided with a drum, clutch-blocks operating within the drum a sliding clutch-collar, and links pivoted together and connected respectively with the clutch-blocks and the clutch-collar and arranged for adjustment into locked position when set to throw the clutch-blocks into engagement with the drum, substantially as set forth.

5. As a means for reversing a pulley on a shaft driven in one direction, the combination of the wheel or pulley having a gear-ring, the shaft on which said gear-ring is loosely fitted, an opposite gear-ring fixed to the shaft, said gear-rings being located within the pulley, the bevel gear-wheels between said opposite gears and within the wheel, a support for said bevel-pinions extending at one end within the pulley, a drum on the other end of said support and provided with a brake-surface, the brake operating upon said surface, and the clutch devices operating within the drum, substantially as set forth.

6. The combination of the shaft, the wheel or pulley loose thereon, and having a gear-ring, reversing devices operating in connection with said gear-ring and including a brake-drum, a brake-band operating upon said drum, clutch devices arranged for operation in connection with the drum, a lever connected with the ends of the brake-band, an operating-lever having its arms connecting with the corresponding arms of the first lever, and means for operating the clutch devices from the said first lever, substantially as set forth.

707,897. **PATTERN-PLATE.** CALVIN R. DAVIS, South Bend, Ind., assignor to Oliver Chilled Plow Works, South Bend, Ind. Filed Mar. 25, 1902. Serial No. 99,235. (No model.)

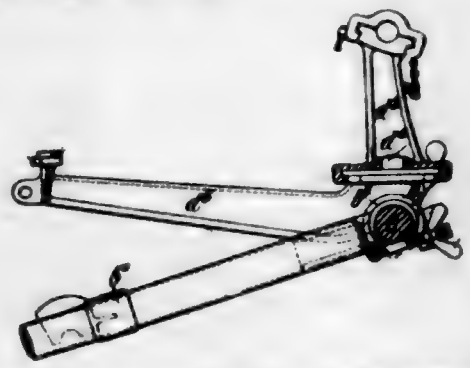
Claim.—1. A pair of coöperating pattern-plates for casting two differently-formed faces of an article, each plate having depressions conforming respectively to the contour of the faces of the article to be molded, and a pattern removably secured to each of said plates.

2. A pair of coöperating pattern-plates for casting two differently-formed faces of an article, said plates having depressions therein conforming respectively to the front and rear faces of the article to be molded, patterns mounted on said plates, each pattern having a contour on one side conforming to the contour of the depression in the plate on which it is mounted and having a contour on its other side conforming to the contour of the depression in the other plate, and means for removably securing said patterns in place on said plates.

3. A pair of coöperating pattern-plates for casting two differently-formed faces of an article and having, respectively, depressions conforming to the contour of respective sides of the article to be cast, one of said plates having a groove surrounding the depression therein, a pattern having a contour for casting one side of an article, located in said depression, Babbitt metal filling the surrounding groove and another pattern having an exterior contour for casting the other side of the article, removably secured in the depression in the other plate.

4. A pattern-plate, comprising a plate having a depression therein, and having a groove surrounding said depression, pins located in said groove, a pattern located in said depression and Babbitt metal located in said groove and embedding said pins, said Babbitt metal serving to secure the pattern to the plate.

707,898. **GUN-CARRIAGE.** ARTHUR T. DAWSON and GEORGE T. BUCKHAM, Westminster, London, England, assignors to Vickers Sons & Maxim, Limited, Westminster, London, England. Filed Feb. 11, 1902. Serial No. 93,566. (No model.)



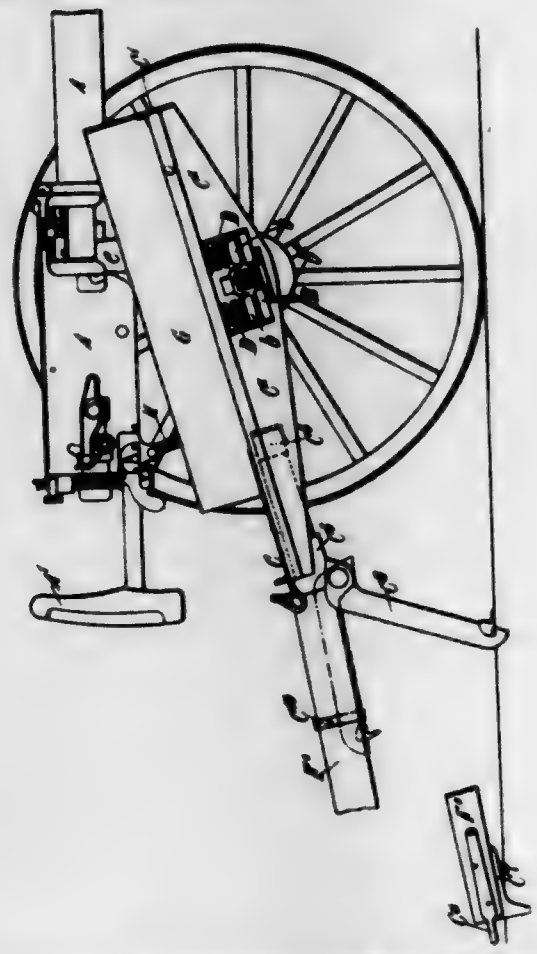
Claim.—1. In a gun-carriage, the combination with the wheel-axle the trail and the top carriage, of U-shaped brackets on the trail, D-shaped

lugs on the axle, means for locking the trail-brackets and lugs together, and a U-shaped bracket on the pivot-plate adapted to rotatably engage with a cylindrical portion of the axle and with bearings in the trail-brackets, for the purpose specified.

2. In a gun-carriage, the combination with the wheel-axle, the trail and the top carriage, of U-shaped brackets on the trail, D-shaped lugs on the axle, hinge-bolts and nuts on the trail-brackets for locking the trail to the axle, and a U-shaped bracket on the pivot-plate rotatably engaging with a cylindrical portion of the axle between the D-shaped lugs thereon, and with concentric lateral and gapped recesses in the trail-brackets said recesses being so disposed relatively to the axle that the trail-brackets and pivot-plate bracket coöperate to lock the trail and the pivot-plate to the axle substantially as described.

3. In a gun-carriage, the combination with the wheel-axle and the top carriage, of a trail composed of two parallel telescopic metal tubes, of cross-pieces connecting together said parallel tubes, U-shaped brackets on said tubes to engage with D-shaped lugs on the axle, means for detachably locking said brackets to said lugs, collars on said axle for preventing lateral movement of the trail on the axle, and a U-shaped bracket on the pivot plate of the top carriage, engaging with a cylindrical part of the axle and with semicircular or gapped lateral recesses in the trail-brackets substantially as and for the purpose specified.

707,399. GUN-CARRIAGE. ARTHUR T. DAWSON and GEORGE T. BUCKHAM, Westminster, London, England, assignors to Vickers Sons & Maxim, Limited, Westminster London, England. Filed Feb. 11, 1902. Serial No. 93,596. (No model.)



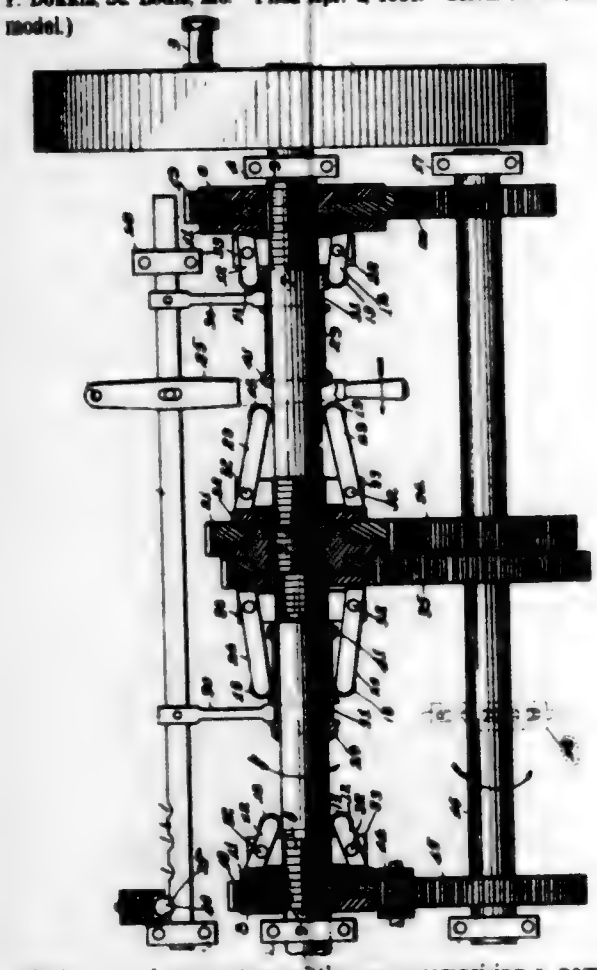
Claim.—1. In a gun-carriage, the combination with the wheel-axle and the frame, of springs interposed between said axle and frame, a cross-piece capable of sliding vertically on said axle, a screw-spindle carried by the axle and adapted to actuate said cross-piece when revolved, and brackets on the frame against which said cross-piece can be caused to firmly abut substantially as and for the purpose specified.

2. In a gun-carriage, the combination with the wheel-axle and the frame, of a draft-pole secured in brackets on said frame, a spade-shoe and a limbering-up eye at the outer end of said pole, a hinged prop of U-section on one of said brackets and means for retaining said prop in its raised position when the carriage is traveling substantially as described.

3. In a gun-carriage, the combination with the wheel-axle and the frame, of ammunition-boxes carried by the frame on opposite sides of the gun and divided into compartments, adjustable inner lids or covers within said compartments and means for locking said lids in the desired adjusted position relatively to the ammunition in the compartments substantially as and for the purpose described.

4. In a gun-carriage, the combination with the wheel-axle and the frame, of ammunition-boxes carried by the frame on opposite sides of the gun and divided into compartments, adjustable inner lids or covers within said compartments, a stud at one end of each of said lids and a bolt at the other end for engaging with a series of vertical notches within the compartments, an eye on the lid for a curved portion of the bolt to engage with, a tongue for passing through said eye to retain the bolt in its engaging position and a handle for facilitating the movement of said lid substantially as and for the purpose described.

707,400. TRANSMISSION-GEAR FOR AUTOMOBILES. GEORGE P. DORRIS, St. Louis, Mo. Filed Apr. 4, 1901. Serial No. 54,294. (No model.)



Claim.—1. A power-transmitting gear, comprising a power-shaft, a number of forward-propelling gears of various sizes and a rearward-propelling gear mounted loosely upon the power-shaft, a number of arms pivotally supported adjacent to each of said gears, a friction-plate interposed between each of said gears and its adjacent arms, sleeves mounted to slide upon the shaft and each sleeve being adapted to operate the arms at a plurality of the gears at different times when the said sleeves are moved continuously in a given direction, to set the friction-plates against the gears to hold the latter, so they will turn with the shaft, a clutch-bar, means for operating said clutch-bar, and connections between the clutch-bar and the sleeves, whereby they will all be moved simultaneously when the clutch-bar is operated, substantially as specified.

2. The combination in a power-transmitting gear, of a number of forward-propelling gears of various sizes and a rearward-propelling gear, a friction-clutch for each of said gears, sleeves constructed to set and release the clutches successively when said sleeves are moved continuously in a given direction and thereby move the driven mechanism forward at various speeds or reverse the same, a clutch-bar and connections between the clutch-bar and the said sleeves and a locking device for holding the clutch-bar in any position, substantially as specified.

3. The combination of a number of forward-propelling gears of various sizes arranged in regular order from the smallest to the largest and a rearward-propelling gear, all mounted on a single shaft, a series of friction-clutches mounted upon the same shaft with the gears, sleeves mounted to slide upon said shaft, each sleeve being adapted to operate a number of the clutches and thereby move the driven mechanism forward at various speeds or reverse the same by setting the clutch of the rearward-propelling gear, a clutch-bar and connections between the clutch-bar and the sleeves, whereby the latter will be operated to set and release all of said clutches successively when the clutch-bar is moved to the limit of its motion in a given direction, substantially as specified.

4. The combination of a series of three or more forward-propelling friction-clutches adapted to transmit variable speeds, a rearward-propelling clutch "double-ended" sleeves adapted to successively engage said clutches when moved continuously in one direction, and operative connections for moving said sleeves, substantially as specified.

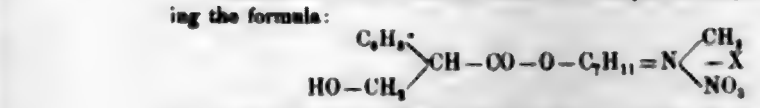
707,401. ORDNANCE POWDER BAG. CARL T. DÖRR, Ehlige, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Mar. 31, 1902. Serial No. 100,859. (No specimens.)

Claim.—1. An ordnance powder-bag consisting of a fabric constructed of threads of smokeless powder, and of textile threads associated in proportions corresponding to inflammability and combustibility desired.

2. An ordnance powder-bag consisting of a fabric produced from threads of smokeless powder, and of textile threads provided with a solution of smokeless powder.

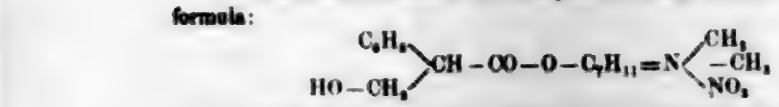
707,402. ATROPINIUM ALKYL NITRATE. HEINRICH DREHER and JÜRGEN CALLSEN, Elberfeld, Germany, assignors to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Filed Apr. 30, 1902. Serial No. 105,283. (No specimens.)

Claim.—1. The herein-described new atropinium alkyl nitrates having the formula:



X meaning an alkyl radical, which bodies represent valuable pharmaceutical compounds, being readily soluble in water and in alcohol and soluble with difficulty in chloroform and ether, substantially as hereinbefore described.

2. The herein-described new atropinium methyl nitrate having the formula:



being a white crystalline body melting at from 163° to 164° centigrade, which is readily soluble in water and in alcohol, soluble with difficulty in ether, acetone and chloroform and exhibiting valuable therapeutic properties, substantially as hereinbefore described.

707,403. PHOTOGRAPHIC DEVELOPER. ARTHUR EICHENGRÜN, Elberfeld, Germany, assignor to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Original application filed Dec. 17, 1901, Serial No. 86,305. Divided and this application filed May 23, 1902. Serial No. 108,702. (No specimens.)

Claim.—The herein-described new developing agent containing a reducing agent, an alkaline agent and acetone alkali bisulfites, substantially as hereinbefore described.

707,404. MIXING-MACHINE. JOHN H. ELWARD, Pretty Prairie, Kans. Filed Mar. 31, 1902. Serial No. 100,853. (No model.)

Claim.—1. In a mixing-machine, for bread and other purposes, the combination with a casing which is substantially cylindrical around a vertical axis of propeller-like rotary arms having their sides inclined relative to vertical planes to produce a horizontal rotation of the mass to be mixed, and means for supporting and turning said arms on a horizontal axis, substantially as set forth.

2. In a mixing-machine for bread and other purposes, the combination of propeller-like rotary arms turning in vertical planes having their sides inclined relative to vertical planes to produce a horizontal rotation of the mass to be mixed and bent longitudinally in the direction of the axis of rotation, a casing which is substantially cylindrical around a vertical axis and means for supporting and turning said arms, substantially as set forth.

3. In a mixing-machine, a casing formed of two parts connected together and relatively adjustable to vary the diameter of the casing.

4. In a mixing-machine, the combination of a casing formed of separate parts adjustable to vary the diameter of the casing, a horizontal shaft passing through the casing, one of the parts of the casing being adjustable on the shaft, and stirrer-blades carried by said shaft.

5. In a mixing-machine, the combination of a casing formed in parts adjustable relative to each other, and means for securing said parts together in their adjusted position.

6. In a mixing-machine, a casing formed of separate parts adjustable to vary the diameter of the casing, and means for connecting said parts consisting of arms *a* and bearings *a'*.

7. In a mixing-machine, a casing formed of separate parts adjustable to vary the diameter of the casing and having supports for resting the same upon the rim of a vessel.

8. In a mixing-machine, a casing formed of separate parts adjustable to vary the diameter of the casing and having supports for resting the same on the rim of a vessel, combined with holding devices adapted to engage beneath such rim.

9. In a mixing-machine, a casing formed of separate parts adjustable to vary the diameter of the casing and having supports for resting the same upon a vessel, combined with elastic and adjustable holders for engaging beneath the rim of such vessel.

10. A portable mixing vessel open at the top and having an open bottom adapted to be detachably fitted to other portable receptacles, and a horizontal mixing-shaft mounted in the lower part of the said vessel and provided with mixing-arms adapted to project to points below the horizontal plane of the top of a lower receptacle when connected to said upper vessel, substantially as set forth.

11. In a mixing-machine, the combination of a vessel, a removable casing above the same, and a horizontal rotary shaft mounted in said casing independent of the vessel and having stirrer-blades or arms extending into said vessel.

12. In a mixing-machine for bread and other purposes, the combination of a vessel, a horizontal shaft and arms carried by the latter operating downwardly and upwardly in the vessel, said arms being curved inwardly and inclined relatively to the planes of rotation, the arms being arranged at one side only of the vessel, the other side of the vessel being free for the circulation of material, substantially as set forth.

13. In a mixing-machine for bread and other purposes, the combination of a vessel which is substantially cylindrical around a vertical axis, a horizontal shaft and arms carried by the latter operating downwardly and upwardly in the vessel, said arms being inclined relative to the planes of rotation, and the arms at one side of the shaft being inclined in a direction opposite to the inclination of the arms at the other side of the shaft, and means for supporting and actuating said arms.

14. In a mixing-machine, the combination of a vessel, a horizontal shaft therein, a sleeve longitudinally adjustable on said shaft and adapted to be rotated thereby, means for connecting the sleeve and shaft against relative longitudinal movement and blades carried by said sleeve, whereby said blades may be adjusted nearer to or farther from the center of the vessel, substantially as set forth.

15. In a mixing-machine, the combination of a casing which is substantially cylindrical around a vertical axis, a horizontal shaft therein, means for rotating the shaft, and propeller-like means on said shaft acting horizontally on the material to produce a circulation of the same in planes substantially parallel with the shaft.

16. In a mixing-machine, the combination of a casing, a horizontal shaft therein, means for rotating the shaft, and propeller-like means on said shaft acting horizontally on the material to produce a circulation of the same in planes substantially parallel with the shaft, said blades acting to force the material in one longitudinal direction on one side of the shaft and in the other direction on the other side of the shaft.

17. An open-bottom casing adapted to be applied to a vessel, and rotary stirring means mounted in said casing and extending below the casing.

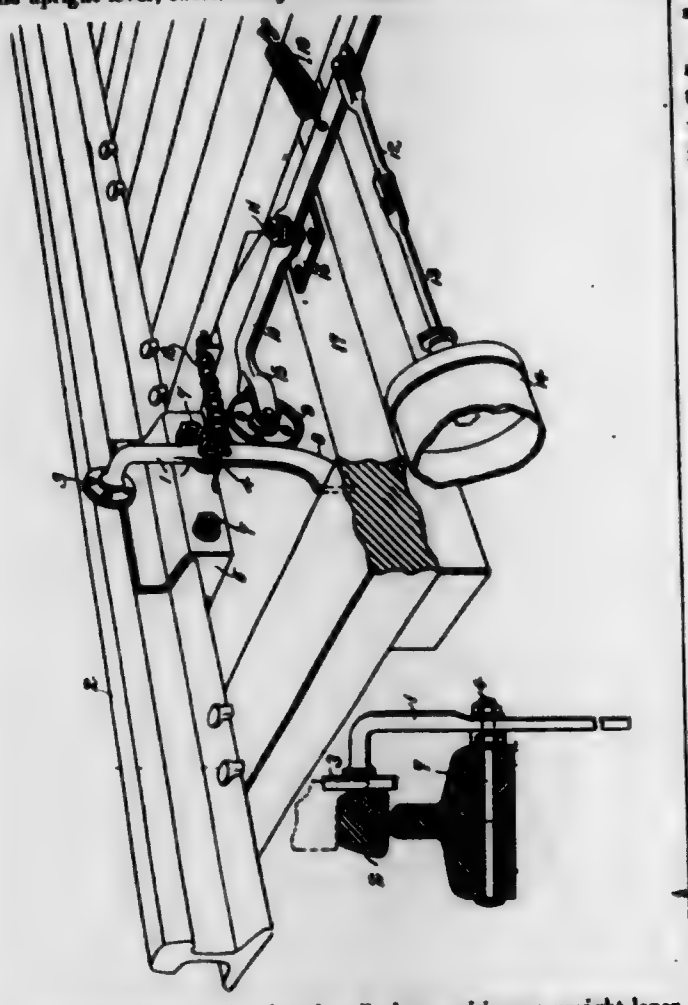
18. An open-bottom casing substantially circular around a vertical axis adapted to be applied to a vessel, a rotary shaft extending across the casing, means for turning the shaft, and stirrers on said shaft, substantially as set forth.

19. In a mixing-machine, the combination with the vessel having vertical walls and adapted to hold fluid materials to be mixed, of a horizontal agitating-shaft mounted across said vessel above the normal level of the materials to be mixed, and vertically-rotating arms carried by said shaft and situated between the center and one end thereof, the remainder of the shaft being free of means for engaging with the material, substantially as set forth.

20. In a mixer, the combination of a vessel having a shaft-bearing in each side thereof, a sleeve having stirring-blades, a shaft insertible from the outside of the vessel into said bearings and said sleeve, the latter being arranged horizontally within the vessel, and means for holding said sleeve on the shaft to turn therewith, substantially as set forth.

707,405. AUTOMATIC RAILROAD-SIGNAL. ALBERT ERICSON and AUGUST S. HOVANDER, Williamsport, Pa. Filed Jan. 22, 1902. Serial No. 90,849. (No model.)

Claim.—1. An apparatus of the class described comprising an upright lever provided at its upper end with a roller or wheel, a spring connected with the lever, an air-pump, and a spring-actuated lever connected with the air-pump and provided with a wheel arranged to be engaged by the upright lever, substantially as described.



2. An apparatus of the class described comprising an upright lever designed to be arranged at the inner side of a rail and fulcrumed between its ends and having a convex edge at its lower arm, an air-pump, and a spring-actuated lever connected with the air-pump and arranged to be engaged by the upright lever, substantially as described.

3. In an apparatus of the class described, the combination of a clamp composed of inner and outer sections conforming to the configuration of the lower portion of a rail, an upright lever fulcrumed between its ends on the clamp, a spring for actuating the lever in one direction, said lever being adapted to be moved in the opposite direction by the wheels of a train, a transverse lever having an antifriction device arranged to be engaged by the lower portion of the upright lever, and means for connecting the transverse lever with the device to be operated, substantially as described.

4. In an apparatus of the class described, the combination of an upright lever fulcrumed between its ends and designed to be arranged at one side of a rail in position to be engaged by the wheels of a train, the lower portion of the upright lever being provided with a curved edge, a lever designed to be connected with the device to be operated and arranged at an angle to the upright lever and provided with an antifriction device to be engaged by the curved edge of the same, and a spring connected with the upright lever, substantially as described.

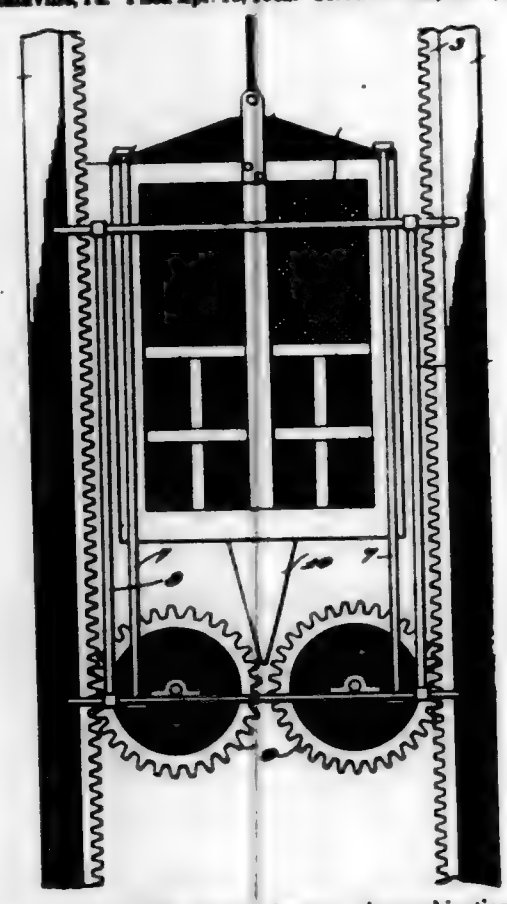
5. An apparatus of the class described comprising an upright lever designed to be located adjacent to a rail and fulcrumed between its ends, the upper arm of the lever being provided with a roller or wheel and the lower arm of the lever having a curved edge, a device designed to be connected with a signal and arranged to be engaged by the lower arm of the upright lever, the latter being also adapted to swing away from the said device, and a spring for holding the lower arm of the upright lever normally in engagement with the said device, substantially as described.

707,406. PICKER-STICK STRAP. CHARLES FABER, Fall River, Mass. Filed Feb. 6, 1902. Serial No. 92,632. (No model.)

Claim.—1. A picker-stick strap for looms, comprising longitudinally-adjustable parts formed at their outer ends with heads, one of which is formed with vertical and transverse apertures and the other with a transverse aperture, means for locking said parts in adjusted position, a yoke, a bolt for engagement with either the transverse or vertical aperture located in the head, whereby the yoke may be attached to a horizontal or vertical swinging rocker-arm of the loom, and a second yoke bolted to the other head and adapted to engage the picker-stick, substantially as set forth.

2. A picker-stick for looms having one end provided with vertical and transverse apertures, of a yoke, a bolt for engagement with either the transverse or vertical aperture, whereby the yoke may be attached to a vertical or horizontal swinging rocker-arm of a loom, substantially as set forth.

707,407. SAFETY-STOP FOR ELEVATORS. WILLIAM PEHLER, Mountainville, Pa. Filed Apr. 10, 1902. Serial No. 102,276. (No model.)



Claim.—1. In a safety-stop for elevators, the combination of toothed guides, a frame carrying gear-wheels engaging the guides, a car or cage slidably connected to said frame, and a wedge upon the car adapted to come between and lock the gear-wheels against rotation upon a downward movement of the car when the hoisting-cable breaks, substantially as and for the purpose set forth.

2. In a safety-stop for elevators, the combination of toothed guides, a car, tie-bolts connected to the car and projecting downward therefrom and having stops at their lower ends, a frame in which said bolts are fitted to slide, the upward sliding movement of the bolts being limited by said stops, gear-wheels carried by the frame and engaging the toothed guides, and a wedge fixed to the bottom of the car and adapted to come between and lock the gear-wheels against rotation upon a downward movement of the car when the hoisting-cable breaks, substantially as specified.

707,408. CASH-REGISTER. GEORGE S. GREEN, Dayton, Ohio assignor, by mesne assignments, to National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Aug. 19, 1898. Serial No. 688,989. (No model.)

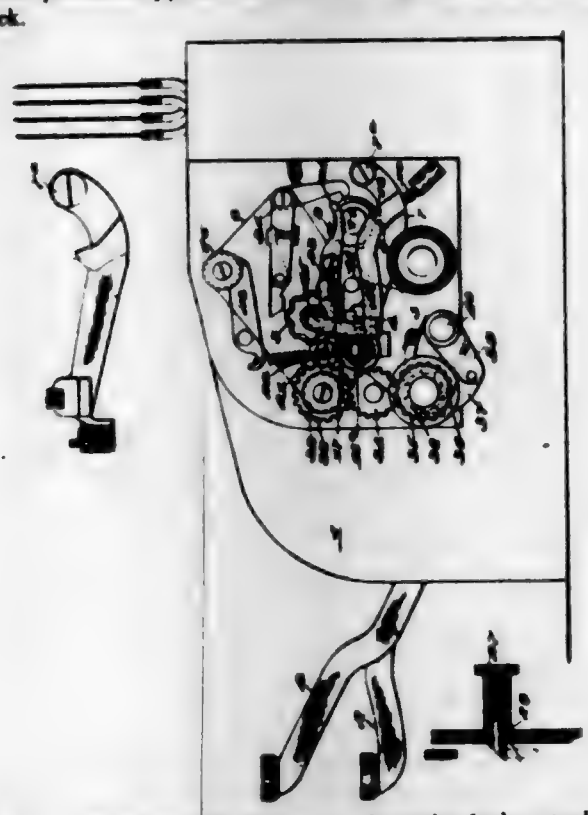
Claim.—1. In a cash-register, the combination with the driving mechanism and type-carriers, of a platen coöperating with the latter, operating means for the platen and an auxiliary operating mechanism arranged to actuate said platen independently of and subsequently to the aforesaid operating means.

2. In a cash-register, the combination with a printing mechanism, of a platen, two independent levers for operating said platen and means arranged to depress said levers and release them successively so as to give the platen two distinct operations.

3. In a cash-register the combination with the driving mechanism and type-carriers, of a movable member carrying a platen, a primary mover for operating said member, and an independent secondary mover operated by the primary mover and arranged to actuate said member after it has been operated by the primary mover.

4. In a cash-register, the combination with a series of keys and the

type-carriers arranged to print upon a paper check, of the platen and a segment or rack arranged to be moved in one direction to feed the check between the platen and type-carriers and in the opposite direction to eject said check.



5. In a cash-register which is arranged to print both a check and detail-strip, the combination with the series of keys and the type-carriers, of a platen, means actuated by the keys for performing the following operations in their assigned order, viz: feeding a loose check forward between the type-carriers and platen, forcing the check against the type-carriers, feeding the check backward, and forcing the detail-strip against the type-carriers.

6. In a cash-register, the combination with the series of keys and the type-carriers arranged to print upon a paper check, of the platen and a lever for operating the platen carrying a segment or rack arranged to feed the check.

7. In a cash-register, the combination with a printing mechanism, of a platen, two independent levers for operating said platen, means for successively operating said levers, and check-ejecting devices arranged to be operated by one of said levers.

8. In a cash-register the combination with a printing mechanism, of a platen, a check-ejector means, a lever for operating the platen, and means carried by the lever for operating the check-ejector means.

9. In a cash-register the combination with a printing mechanism, of a platen, a lever for operating said platen, a check-ejector means, and a segment or rack carried by said lever and arranged to operate said check-ejector means.

10. In a cash-register, the combination with a printing mechanism, of a platen, a lever for operating said platen, check-feeding disks operated by said lever and arranged to clamp the check between them and means coöperating with the said disks to separate them and release the check when it is to be ejected.

11. In a cash-register the combination with a printing mechanism, of a check-feeding disk, movable spring-pressed means carrying another feeding-disk arranged to contact with the first-named disk, devices for moving said disks to first feed a check forward and then to retract it, and means for automatically separating the disks to release the check when it is to be ejected.

12. In a cash-register, the combination with a printing mechanism, of a platen, two independent levers for operating said platen, springs for normally forcing said levers toward the printing mechanism and a cam connected to the movable parts of the machine and arranged to depress said levers against the tensions of their springs and then successively release them so that each in turn will cause a printing action of the platen.

13. In a cash-register, the combination with a printing mechanism, of a platen, two independent levers for operating said platen and a cam arranged to retract both levers and to afterward successively release them.

14. In a cash-register, the combination with a printing mechanism, of a platen, two independent levers for imparting a double stroke to said platen, a rack mounted on one of said levers and check-feeding devices meshing with said rack.

15. In a cash-register, the combination with a printing mechanism, of an operating-lever carrying a platen, an independent lever for operating said platen, and a cam engaging said levers and arranged to disengage therefrom at different times so that said levers are successively operated.

16. In a cash-register, the combination with a printing mechanism, of a platen, platen-operating means and an auxiliary independent operating device for said platen arranged to actuate the platen subsequent to its operation by the first-mentioned platen operating means.

17. In a cash-register, the combination with a printing mechanism, of a check-feeding mechanism comprising a feeding-roller, a projection mounted on said roller and arranged to act as a check-stop and a check-ejecting means.

18. In a cash-register the combination with the series of keys and type-carriers arranged to print upon a paper check, of the platen and devices arranged to move in one direction to feed the check between the platen and the type-carriers and in the opposite direction to eject said check.

19. In a cash-register the combination with a printing mechanism, of a platen, two independent levers for operating said platen, means for successively operating said levers, and check-ejecting devices arranged to be operated between the operations of the levers.

20. In a cash-register the combination with a printing mechanism, check-feeding disks, means arranged to operate said disks first in one direction and then in the other and devices coöperating with the said disks to separate them and release the check when it is to be ejected.

21. In a cash-register, the combination with a printing mechanism, of a lever carrying a platen, a second lever for operating said platen carrying a rack, a check-feeding disk carrying a pinion meshing with said rack, and a spring-pressed companion disk movable toward and from the first-mentioned disk.

22. In a cash-register, the combination with a printing mechanism, of a lever carrying a platen, a second lever for operating said platen carrying a rack and a check-feeding disk carrying a pinion which meshes with said rack.

23. In a cash-register, the combination with a printing mechanism, of a lever carrying a platen, a check-ejector means, a second lever for operating the platen and a rack carried by said second lever and arranged to operate the check-ejector.

24. In a cash-register, the combination with a printing mechanism, of a lever carrying a platen, a check-ejector means, a second lever for operating the platen and means carried by said second lever for operating the check-ejector means.

25. In a cash-register, the combination with a printing mechanism, of check-feeding devices arranged to be moved first in one direction to feed a check into coöperative relation with said mechanism and then in an opposite direction to eject said check.

26. In a cash-register, the combination with a series of keys, of type-carriers moved thereby, a platen, and devices arranged to be moved in one direction to feed a check and in the opposite direction to eject said check.

27. In a cash-register the combination with the series of keys, arranged to be operated by hand-pressure upon the same, of type-carriers arranged to be moved by said keys, a platen coöperating with said type-carriers and independent devices actuated by the keys for bringing said type-carriers and platen together twice during each operation of the keys.

28. In a cash-register, the combination with a printing mechanism, of a lever carrying a platen, a second lever for giving the platen a second operation and means for locking said second lever out of operative position at will.

29. In a cash-register, the combination with a printing mechanism, of a platen, independent devices for giving the platen two operations at each single operation of the machine and means for preventing one of said platen operations at will.

30. In a cash-register, the combination with a printing mechanism, of a platen, a lever for operating said platen independently of its regular operation, and means for rendering said lever inoperative at will.

31. In a cash-register, the combination with a printing mechanism, of a platen, two independent spring-pressed levers for operating said platen and means arranged to depress said levers against the tensions of their springs and release them successively so as to give the platen two distinct operations.

32. In a cash-register, the combination with a printing mechanism, of two independent spring-pressed levers, a platen mounted on one of said levers, a projection mounted on the remaining lever and arranged to engage the first-mentioned lever, and means arranged to depress said levers against the tensions of their springs and release them successively so as to give the platen two distinct operations.

33. In a cash-register, the combination with a printing mechanism, of a platen, two independent spring-pressed levers for operating said platen, and two cams arranged respectively to engage said levers, depress them against the tensions of their springs and release them successively so as to give the platen two distinct operations.

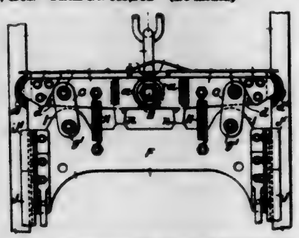
34. In a cash-register, the combination with a driving mechanism and type-carriers, of a platen coöperating with the latter, operating means for the platen connected to the driving mechanism, and an independent operating device for the platen also connected to the driving mechanism and arranged to automatically operate said platen subsequent to its operation by the first-mentioned means.

35. In a cash-register, the combination with a driving mechanism and type-carriers, of a platen coöperating with the latter, operating means for the platen connected to the driving mechanism, an independent operating device for the platen also connected to the driving mechanism, and check-feeding devices arranged to be operated by said independent platen-operating devices.

707,409. WASHING-MACHINE. OREN GUTAR, Columbia, Mo. Filed Nov. 1, 1900. Serial No. 35,705. (No model.)

Claim.—In a washing-machine of the class described, the combination, with the cylindrical rods-holder, of the rotatable clothes-holder comprising four radial, rectangular receptacles having perforations in their parallel sides and outer ends, and curved flanges which are arranged at the outer corners of said receptacles, their convex sides being placed in contact and thus curving in opposite directions, as shown and described for the purpose specified.

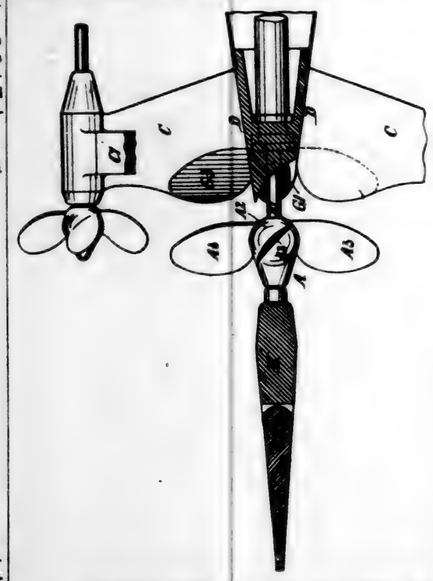
707,410. SAFETY SUSPENDING APPARATUS FOR ELEVATORS OR THE LIKE. BARTHOLOMEW HARRWOOD, Hull, England. Filed Apr. 29, 1902. Serial No. 105,944. (No model.)



Claim.—A safety apparatus for mine and lift cages, skips and the like, consisting of a pair of toggle-levers in angular relation to each other, united by a common pivotal joint connected to the hoisting-rope, and terminating at their outer ends in dogs of V form with narrow pyramidally-toothed cutting faces in immediate proximity to the faces of the cage-guides, in combination with a cross-beam, pairs of connecting-links pivoted to the toggle-levers and to the cross-beam, springs connected to the cross-beam and applied to act on the toggle-levers in opposition to the pull of the hoisting-rope, so as to tend to straighten the toggle-levers and cause their cutting faces to be thrust into forcible contact with the cage-guides, abutments on the cross-beam and stops on the levers counting with the connecting-links, to limit the normal angular relation of the toggle-levers under the pull of the rope, and a stop to prevent the descent of the common pivotal axis of the toggle-levers below the common line of centers of these levers, substantially as herein described.

707,411. MEANS FOR MOORING PROPELLERS OF SHIPS. JAMES HAMILTON, Glasgow, Scotland. Filed Apr. 8, 1902. Serial No. 101,923. (No model.)

Claim.—1. A ship having a propeller and shaft adapted to be moved longitudinally, and after portions of the ship in line with the propeller-blades, said after portions being shaped to conform with the propeller-blades, substantially as and for the purpose described.



2. A ship having a plurality of propellers, one propeller longitudinally movable, after portions of the ship in the way of each propeller, angular parts or surfaces on said after portions and shaped as counterparts of the blades to fit the surfaces of the blades, the propeller being adapted to be drawn up against the said angular or counterpart surfaces, substantially as set forth.

3. A ship having a central propeller and two wing propellers, a stern-post, with a bracket on each side of it adapted to carry the wing propellers, angular parts on the stern-post and brackets shaped as counterparts of the propeller-blades to fit the forward surfaces of the blades of the central propeller, a recess in the stern-post and for the boss of said propeller, the propeller being adapted to be drawn inward or forward from its working position till its blades engage against the angular or counterpart surfaces provided for them as aforesaid on the stern-post and side brackets, substantially as and for the purpose set forth.

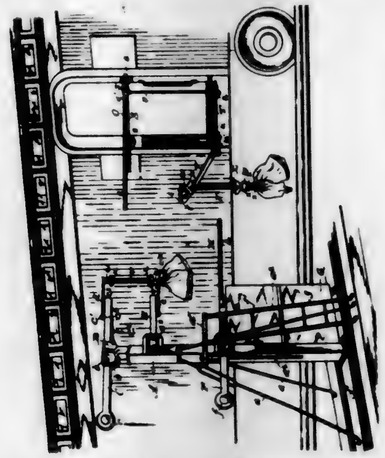
707,412. RECEIVING AND DELIVERING APPARATUS FOR MAIL-BAGS. AUGUSTUS P. HAHN, New Albany, Ind. Filed May 27, 1902. Serial No. 108,182. (No model.)

Claim.—1. In an apparatus for receiving and delivering mail-bags, a receiving-arm having a receiving-slot and retaining-hole, a dog adapted to move forward across the receiving-slot, a stop for said dog, and a trip-lever located in the retaining-hole and adapted to actuate the dog, said trip-lever being operated by contact of the mail-bag therewith.

2. In an apparatus for receiving and delivering mail-bags, a receiving-arm having a receiving-slot and retaining-hole, a dog adapted to swing outward across the receiving-slot, a slot for said dog, and a curved trip-lever pivoted to the receiving-arm in the rear part of the retaining-hole, one end of said lever being adapted to engage and throw the dog and the other end located for contact of the mail-bag therewith, substantially as shown and described.

3. In an apparatus for receiving and delivering mail-bags, a receiving arm or fork one member of which is provided with a shoulder forming a stop, a dog pivoted to the other member of the fork and adapted to be swung forward across the fork and engage the said stop, and a trip-lever for actuating the dog, said trip-lever being pivoted in the rear end of the fork and having one end in the path of the mail-bag.

4. In a receiving and delivering apparatus for mail-bags, a receiving-arm or catcher-fork, a dog pivoted in a recess in one member of the fork and adapted to extend across and engage a recess in the other member, and a curved trip-lever located in a recess in the fork, one end of said lever being adapted to engage the dog and the other end projected in the path of the mail-bag, so as to throw the dog when said projecting end is struck.



5. In a receiving and delivering apparatus for mail-bags, a crane, comprising a post or standard having delivering means at its upper end, a receiving-arm carrying a plate, and a wall or guide-plates between which the aforesaid plate is adapted to move, the said plates reinforcing the receiving-arm and forming a buffer for the mail-bag.

6. In a receiving and delivering apparatus for mail-bags, a crane comprising a post or standard, a pivoted supporting-arm carrying a receiving-arm, a plate attached to said supporting-arm, and a stationary guide-plate on a line with the aforesaid plate, the said plates reinforcing the receiving-arm and forming a buffer for the mail-bag.

7. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard, an arm pivoted in the upper end thereof and weighted at its rear end, a bar swiveled to the arm and provided with a clamping-jaw at its outer end, a second arm pivoted to the standard below the aforesaid arm and having a bar with a clamping-jaw, an arm pivoted in a slot in the standard, said arm being weighted at its rear end and provided with receiving-arms at its forward end, a plate attached to the last-mentioned arm, and a stationary guide-plate located on a line with the aforesaid plate, substantially as shown and described.

8. In a receiving and delivering apparatus for mail-bags, the combination with the crane, of a standard or post having delivering mechanism at its upper end and slotted near its lower end, a supporting-arm pivoted in said slot and carrying receiving-arms, a plate attached to said supporting-arm, and stationary guide-plates between which the aforesaid plate works, substantially as shown and described.

9. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard having a vertical slot therein, a supporting-arm pivoted in said slot and weighted at its rear end, a plate attached to said supporting-arm, and stationary guide-plates for the aforesaid plate, substantially as shown and described.

10. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard having a vertical slot therein, a supporting-arm pivoted in said slot, receiving-arms at the forward end of said supporting-arm, a plate attached to the supporting-arm, and stationary guide-plates for the aforesaid plate, substantially as shown and described.

11. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard, a supporting-arm pivoted thereto and carrying a receiving-arm at its forward end, and a plate attached to and depending from said arm.

12. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard, a supporting-arm pivoted thereto, a plate attached to said supporting-arm and means for bracing the lower or free end of said plate.

13. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard, a supporting-arm pivoted thereto, a plate attached to said supporting-arm and depending therefrom, and means for bracing the lower end of the plate.

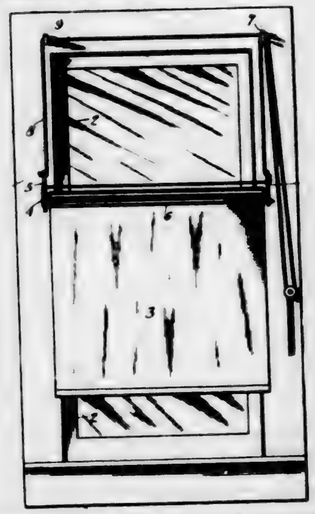
14. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard, a supporting-arm pivoted thereto and weighted at its rear end, catcher-arms at the forward end of said supporting-arm, a plate attached to the supporting-arm below the catcher-arms, and means for bracing the outer end of said plate.

15. In a receiving and delivering apparatus for mail-bags, the combination, of a post or standard slotted at its lower end, a supporting-arm pivoted in said slot and weighted at its rear end, catcher-arms secured to the forward end of said supporting-arm, a plate attached to the supporting-arm below the catcher-arms and bearing at its rear end in the aforesaid slot, and guide-plates attached to the post or standard below the aforesaid plate, and between which the lower end of the aforesaid plate is guided.

16. In a delivering and receiving mechanism for mail-bags, a suspending means for the mail-bag, comprising a flexible rod having rings at its ends, and disk-forming stops at either side of the center of said rod.

17. A suspending means for mail-bags, comprising a rope having rings attached to the ends thereof, disks secured to the rope at either side of the center thereof to form stops, and a leather and canvas covering between the stops, substantially as shown and described.

707,418. ADJUSTABLE WINDOW-SHADE HOLDER. PRESCOTT D. HEWES and FREDERICK J. RITTER, New York, N. Y. Filed Apr. 19, 1902. Serial No. 103,700. (No model.)



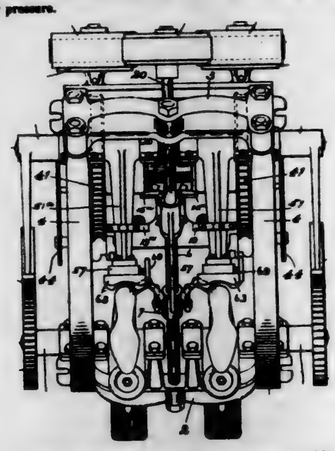
Claim.—1. In a device of the class described, a plate provided with a central round opening to receive a gudgeon at one end of a roller and with a perforation above and below said opening, a plate provided with a central rectangular opening to receive the rectangular gudgeon at the other end of the roller and with a perforation above and below such rectangular opening, a flexible member threaded through such perforations and retaining the plates in operative position, and adjustably mounted on the window-frame and a second flexible member secured to one of such plates and adjustably mounted upon the window-frame.

2. In a device of the class described, a plate provided with a central round opening to receive the gudgeon at one end of a roller and with a perforation above and below such opening, a plate provided with a central rectangular opening to receive the gudgeon at the other end of the roller and with a perforation above and below such opening and with a projection on the inner side of its upper portion, a cord secured at one end in the lower perforation of the first-mentioned plate and threaded through the perforations in the other plate and then through the upper perforation in the first-mentioned plate and secured near the upper end of said last-mentioned plate, a cord secured to said projection, and pulleys secured at the upper part of the window-frame to receive said cords.

707,414. LEVELING-MACHINE. JOHN J. HEYD, Lynn, Mass., assignor of one-half to Maurice V. Brosnahan, Lynn, Mass. Filed Apr. 25, 1901. Serial No. 57,431. (No model.)

Claim.—1. In a leveling-machine, a mold arranged to travel in a uniform arc, a complemental yieldingly-mounted last arranged to travel in a complemental arc, and means controlled by the bottom of the sole of the boot or shoe for limiting the movement of the last up or down whereby the sole of the boot or shoe upon the last is caused to move in the same arc, irrespective of the thickness of the sole.

2. In a leveling-machine, a mold arranged to travel in the arc of a circle, a complemental last and its standard, a pivoted support provided with two pivoted arms that are pivotally connected to said standard, and adjustable yielding connections between one of said arms and the support whereby the last may be given a predetermined yielding resistance and adjustment without changing the position of the bottom of the sole of the boot or shoe with relation to the axis of said support while the said sole is under pressure.



3. In a leveling-machine, two independent sets of molds and lasts confined to movement in the arc of a circle, and means connected with the lasts for automatically regulating the amount of pressure applied to the sole of the boot or shoe without changing the arc of movement of the mold or of the surface of said sole when under pressure.

4. In a leveling-machine, a mold-bed adapted for attachment to an arm or support, a mold formed with a locking member at one end, and at its other end carrying an adjusting member, said members being adapted to engage complemental members upon the mold-bed.

5. In a leveling-machine, a mold-bed adapted for attachment to an arm or support, a mold formed with a locking member at one end, and at its other end carrying an adjusting member, said members adapted to engage complemental members upon the mold-bed and means for locking the mold to the bed.

6. A mold for a leveling-machine, formed with a locking member at one end, and at its other end with an adjusting member.

7. In a leveling-machine, a last, a standard having provisions for attaching a last thereto, and an adjustable stop carried by the standard arranged to engage complemental means upon the last, whereby the sole of the last may be maintained in a predetermined plane irrespective of the size or shape of the last or the wear of its crown due to pressure, &c.

8. In a leveling-machine, two sets of pivoted molds and complemental lasts confined to movement in the arc of a circle, and automatic means for causing either of said sets to perform a predetermined number, one or more, of pressing operations and then stop with the last in a position of clearance.

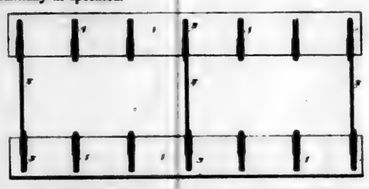
9. In a leveling-machine, a last having provisions for attachment to a standard and a pressure-resisting face upon the crown of said last adapted for engagement with a complemental support upon the jack or standard.

10. In a leveling-machine, a mold, a last, means for moving said parts in complemental arcs, comprising a last-standard, a pivoted support carrying two pivoted arms that are pivotally connected to said standard and yielding means engaging one of said arms whereby the last is yieldingly supported and will recede from or advance toward the mold in parallel lines irrespective of the point of contact between the mold and last.

11. In a leveling-machine, two sets of molds and complemental lasts, means for moving the last and mold of each set in complemental arcs and means whereby the last at the completion of the pressing operation is automatically brought to a vertical position of clearance.

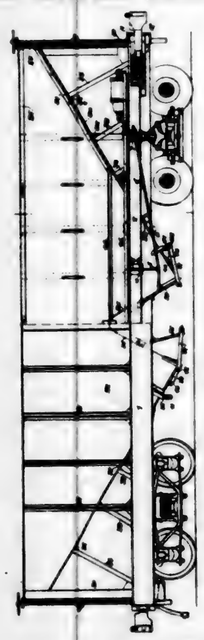
707,415. CELLULAR PACKING STRUCTURE. HOWARD H. HOBAR, Philadelphia, Pa. Filed June 27, 1900. Serial No. 21,001. (No model.)

Claim.—1. A cellular structure consisting of upper and lower cellular portions composed of interlocking cross-strips and connecting portions of less thickness than the strips in said cellular portions, the upper and lower portions of said connecting-strips being doubled and cemented together throughout the extent of the doubled portion in order to impart to them the thickness necessary for the strips of the cellular structure, substantially as specified.



2. A cellular packing structure composed of interlocking cross-strips each consisting of two or more thicknesses of material cemented together throughout their extent and a bottom sheet having upturned and folded edges also cemented together throughout the extent of the fold, and each constituting one of the strips of the cellular portion of the structure, substantially as specified.

707,416. METALLIC RAILWAY-CAR. RAYMOND H. HORSENDEN, Philadelphia, Pa., and WILLIAM H. WOODCOCK, Canton, Ohio. Filed Oct. 18, 1901. Serial No. 78,885. (No model.)



Claim.—1. A metallic car-frame having longitudinal side sills composed of channel-bars and a center sill composed of channel-bars of less depth than the side sills but provided with longitudinal truss-rods, substantially as specified.

2. The combination of the opposite channel-bars of the center sill, the transverse body-bolsters and longitudinal truss-rods bearing upon struts depending from the sill, said truss-rods passing through the body-bolsters and having nuts bearing thereupon, substantially as specified.

3. The combination of the opposite channel-bars, of the center sill with the body-bolsters, separator-plates interposed between and secured to the bars of the center sill, struts secured to and depending from said separator-plates, and longitudinal truss-rods bearing upon said struts and passing through the body-bolsters, substantially as specified.

4. The combination in a metallic car-frame, of side and center sills, with an end sill having inner and outer angle-bars secured to said center and side sills, substantially as specified.

5. The combination in a metallic car-frame, of side and center sills, with an end sill having inner and outer angle-bars at the top, and an outer angle-bar at the bottom, all of said bars being secured to the center and side sills, substantially as specified.

6. The combination in a metallic car-frame, of center and side sills with an end sill having inner and outer angle-bars at the top, an outer angle-bar at the bottom, and a transverse plate extending from top to bottom, said bars and plate being secured to the center and side sills, substantially as specified.

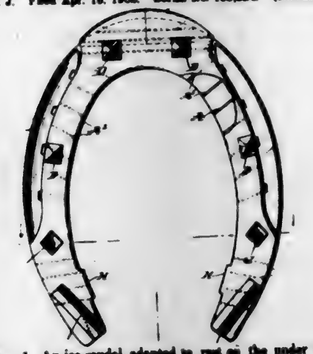
7. The combination in a metallic car-frame of the side sills and the end sills with diagonal braces extending from the corners of the frame and having bent ends connected to the said side sills, and a channel-bar connected to the brace and to both side and end sills, substantially as specified.

8. The combination in a metallic car-frame of the side sills, the center sills, the end sills, and the transverse body-bolster with diagonal braces extending from the corners of the frame formed by the junction of the end sills and the side sills to the angles formed by the junction of the center sill and body-bolsters, said diagonal braces presenting horizontal flanges secured to the flanges on the bolster and vertical flanges secured to the bolster and center sills, substantially as specified.

9. The combination of the upright sides of a metallic car with the transverse top braces consisting of rods having end eyes, angle-bars secured to the inner sides of the car and serving as vertical braces therefor, and bolts whereby the eyes at the ends of the transverse rods are secured to the said angle-bars, substantially as specified.

10. The combination of the end sills and upright corner-posts of a metallic car-frame, plates secured to and projecting inwardly from said corner-posts, and stay-rods extending diagonally from post to post and having shackles whereby they are secured to said inwardly-projecting plates, substantially as specified.

707,417. ICE-SANDAL FOR FLAT HORSESHOES. ISRAEL G. HOWELL, Hopewell, N. J., assignor of one-half to Matteo di Puglia, Hopewell, N. J. Filed Apr. 18, 1902. Serial No. 103,594. (No model.)



Claim.—1. An ice-sandal adapted to rest on the under side of a horseshoe, and provided with depending points and heels, belts for securing the sandal to the shoe at or about the quarters thereof, and a flange on the toe of the sandal, to engage a recess on the edge of the horseshoe-toe, as set forth.

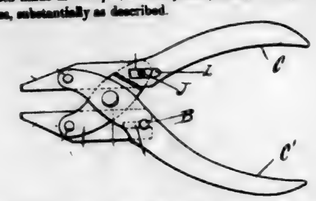
2. An ice-sandal adapted to rest on the under side of a horseshoe, and provided with depending points and heels, belts for securing the sandal to the shoe at or about the quarters thereof, a flange on the toe of the sandal, to engage a recess on the edge of the horseshoe-toe, and lugs on the inside of the sandal, to fit the inner edges of the sides of the shoe, at or about the quarters or heels, as set forth.

3. An ice-sandal fitting the under side of a horseshoe and formed on its side edges with cut-out portions, to leave the nail-grooves of the horseshoe unobstructed, the said sandal being provided with depending points and heels, belts for securing the sandal to the shoe, and a flange on the toe of the sandal to engage a recess in the rim of the horseshoe-toe, as set forth.

707,418. PLIERS. MATTHEW M. HOWLAND, Providence, R. I. Filed Feb. 3, 1902. Serial No. 92,802. (No model.)

Claim.—1. In pliers, the combination of an upper jaw and handle made in one piece, a lower handle having a fork at its front end pivoted to the upper jaw, a lower jaw held in said fork and connected with the upper handle by a plate, or plates pivoted to the lower jaws at their front ends, and connected to the upper handles by a pin passing through the plates and a slot in said handle, means to prevent said pin from moving in said slot when the jaws are opened by their front ends, a main pivot passing through said plates and fork, substantially as described.

2. In pliers, the combination of an upper jaw and handle made in one piece, a lower handle having a fork at its front end pivoted to the upper jaw, a lower jaw held in said fork and connected with the upper handle by a plate, or plates, pivoted to the lower jaw at their front ends and connected to the upper handles by a pin passing through the plates, and a slot in said handle, teeth made in the upper side of said slot, one or more teeth made in said pin, a main pivot passing through said fork and the plates, substantially as described.



3. A device of the character described, comprising a one-piece jaw and handle member; a separate handle member pivoted at one end to said member near its jaw portion; a separate jaw member having a slot at its inner end portion; a pin on the said handle member engaging the walls of said slot and slidable therein; said jaw and handle member having a slot at an intermediate portion; and a connecting member having a pin at one end slidable in said last-mentioned slotted portion; the connecting member having its other end pivoted to said separate jaw member at an intermediate part thereof; said separate handle member being pivoted intermediate of its said attaching parts to the intermediate part of the said connecting member.

4. In a device of the character described, the combination of a jaw and handle in one piece, a separate jaw, a separate handle, means for giving said jaws a parallel motion, and means for automatically locking the jaws on an object in the same.

5. In a device of the character described, a jaw and handle in one piece, a separate handle, a separate jaw, means for giving said jaws a parallel motion, in combination with means for automatically locking said jaws.

6. In parallel pliers, a jaw and handle in one piece, a separate jaw, a plate or plates having pins in each end engaging said separate jaw and said one-piece jaw and handle, and a separate handle pivoted on said separate jaw and the one-piece jaw and handle.

7. In parallel pliers, a jaw and handle in one piece, a separate jaw, a plate or plates having pins in each end engaging said separate jaw and said one-piece jaw and handle, a separate handle pivoted on said plate or plates having pins engaging said separate jaw and the one-piece jaw and handle, substantially as described.

707,419. SKYLIGHT. EDGAR J. HULSE, Washington, D. C. Filed Jan. 20, 1902. Serial No. 90,573. (No model.)

Claim.—1. The ridge-bar of a skylight provided with a supporting member having a central web with gutters at the lower end on opposite sides thereof, outturned flanges 3, 3, below the gutters, and a clamping-strip folded over at the edges to grip said flanges, substantially as set forth.

2. The ridge-bar provided with a bearing member consisting of a metallic sheet doubled on itself to form a doubled vertical web, extended outward at each side at the lower end of the web and bent to form upwardly-extending flanges of double thickness, and with downwardly-extending converging portions having outturned flanges 3, and means for connecting together said flanges 3, substantially as set forth.

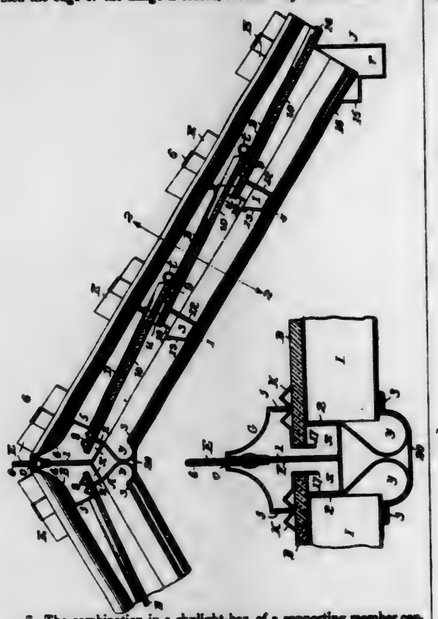
3. The ridge-bar provided with a bearing member consisting of a metallic sheet doubled on itself to form a doubled vertical web, extended outward at each side at the lower end of the web, and bent to form upwardly-extending flanges 2 of double thickness, and with downwardly-extending converging portions having outturned flanges 3, and a clamping-strip for connecting together said flanges 3, substantially as set forth.

4. The combination with a glass of a skylight, of a bearing consisting of a metallic strip bent to form parallel supporting-ribs, said ribs resting on said glass and forming a support for an overlapping glass, and the outer side of the outer rib extending downwardly and held in contact with the supporting-glass by the weight of the overlapping glass, substantially as set forth.

5. The combination with a glass of a skylight, of a bearing consisting of a metallic strip bent to form parallel supporting-ribs, said ribs resting on said glass and forming a support for an overlapping glass, the outer side of the outer rib extending downwardly and held in contact with the supporting-glass by the weight of the overlapping glass, and said strip having a downturned flange to fit over one end of the supporting-glass, substantially as set forth.

6. The combination with the glass of a skylight structure, of a member having a flange substantially perpendicular to said glass and a seal-

ing-piece consisting of a bent metallic strip having parallel ribs between which the edge of the flange is seated, substantially as set forth.



7. The combination in a skylight-bar, of a supporting member consisting of a strip bent to form a central web and two side flanges, each of double thickness, and with downwardly-extending converging parts with outwardly-extending lower flanges, and a clamping-strip folded over at the edges to grasp said flanges, substantially as set forth.

8. The combination in a skylight-bar, of a supporting member consisting of a strip bent to form a central web and two side flanges, each of double thickness, and with downwardly-extending converging parts with outwardly-extending lower flanges bent upward to form side gutters, and means for connecting together the converging parts, substantially as set forth.

9. The combination in a skylight-bar, of a supporting member consisting of a strip bent to form a central web and two side flanges, each of double thickness, and with downwardly-extending converging parts with outwardly-extending lower flanges, and a clamping-strip extending beneath said parts and connected with the edges thereof, substantially as set forth.

10. The combination with the supporting and cap members, of the sealing-pieces consisting of corrugated strips, the flanges of the cap members seated in the corrugations of said pieces, substantially as set forth.

11. The double cross-gutter consisting of a strip bent to form gutters *p* and *q* and doubled flanges, 18 and 19 and seat 20, substantially as set forth.

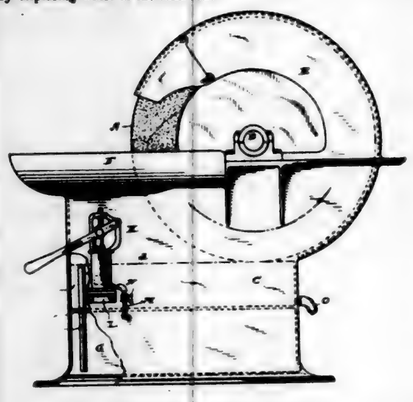
12. The inclined supporting-bar consisting of a strip of metal bent to form side bearings with vertical flanges 2, 2, each with a series of inclined edges and intermediate shoulders, combined with glass panes resting on said edges and projecting below said shoulders overlapping each other and with intermediate corrugated parting-strips, substantially as set forth.

13. The inclined supporting-bar consisting of a strip of metal bent to form side bearings with vertical flanges 2, 2, each with a series of inclined edges and intermediate shoulders, combined with glass panes resting on said edges and projecting below said shoulders overlapping each other and with intermediate corrugated parting-strips, consisting each of a strip of metal having corrugations and a flange extending across the edge of the lower pane, substantially as set forth

---

707,420. APPARATUS FOR WETTING EMERY-WHEELS. ELWIN E. HYDE, Bridgeport, Conn. Filed July 31, 1901. Serial No. 70,884. (No model.)

Claim.—The combination with a tank and a reservoir, of a pipe extending from near the bottom of the reservoir to the normal water-line in the tank, an air-pump and a pipe leading therefrom into the reservoir, whereby water may be maintained at the normal water-line in the tank by displacing water in the reservoir.



707,421. PROCESS OF PRODUCING TRICHROMATIC HALF-TONE-PROCESS NEGATIVES. FREDERIC E. IVES, Philadelphia, Pa. Filed June 30, 1902. Serial No. 113,732. (No specimens.)

Claim.—1. The mode herein described of producing trichromatic half-tone-process negatives, said mode consisting in simultaneously exposing three elements of the color-record through three half-tone-process screens having different dispositions of pattern and with dioptric light adjustment to meet the requirements of screen half-tone-process negative-making, substantially as specified.

2. The mode herein described of producing trichromatic half-tone-process negatives, said mode consisting in simultaneously exposing the three images of a color-record through the three half-tone-process screens having different dispositions of pattern and with dioptric light adjustment to meet the requirements of screen half-tone-process negative-making, and independent of adjustment for equalizing the chromatic light action upon the three images, substantially as specified.

3. The mode herein described of producing trichromatic half-tone-process negatives, said mode consisting in simultaneously exposing the three elements of a color-record through a single lens and diaphragm, and through three half-tone-process screens having different dispositions of pattern, substantially as specified.

707,422. PHOTOGRAPHIC ATTACHMENT FOR OPTICAL INSTRUMENTS. FREDERIC E. IVES, Philadelphia, Pa. Filed June 30, 1902. Serial No. 113,733. (No model.)

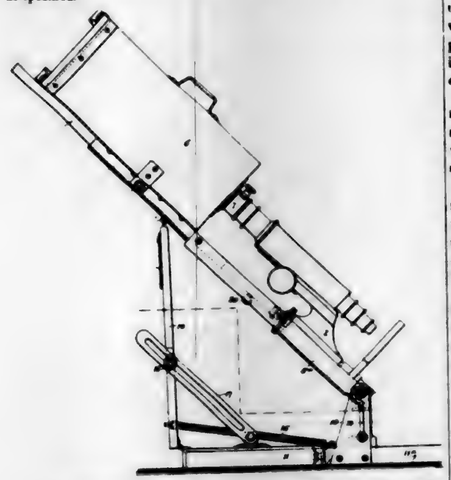
Claim.—1. The combination of an optical instrument having an eye-piece, with a camera complete with lens having a fixed focus similar to the image distance of the instrument, whereby the image seen in the eye-piece is reproduced without alteration of focus, definition or amplification, substantially as specified.

2. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby said camera is mounted in position for use in connection with an optical instrument, substantially as specified.

3. A camera focused for parallel rays and movable to and fro as a rigid whole in the line of its optical axis, in combination with a support whereby said camera is mounted in position for use in connection with an optical instrument, substantially as specified.

4. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby said camera is mounted in position for use in connection with an optical instrument, said support having as an element a base constructed to engage the base of said instrument, substantially as specified.

5. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby the camera is mounted in position for use in connection with an optical instrument, one of the elements of said support being a strut whereby the support is braced and stiffened when the camera is in position for use, substantially as specified.



6. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby the camera is mounted in position for use in connection with an optical instrument, one of the elements of said support being a pivoted strut whereby the support is braced and stiffened when the camera is in position for use, substantially as specified.

7. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby the camera is mounted in position for use in connection with an optical instrument, elements of said support being a base constructed for engagement with the base of said instrument, and a strut whereby the support is braced and stiffened when the camera is adjusted in position for use, substantially as described.

8. A camera focused for parallel rays and movable to and fro in the line of its optical axis, in combination with a support whereby the camera is mounted in position for use in connection with an optical instrument, elements of said support being a base constructed for engagement with the base of said instrument, and a pivoted strut whereby the support is braced and stiffened when the camera is adjusted in position for use, substantially as specified.

9. A camera focused for parallel rays and movable to and fro in the line of its optical axis, and a support whereby said camera is mounted in position for use in connection with an optical instrument, elements of said support being a base engaging the base of the instrument, and a strut interposed between said base and that portion of the support upon which the camera is mounted, substantially as specified.

10. A camera focused for parallel rays and movable to and fro in the line of its optical axis, whereby said camera is mounted in position for use in connection with an optical instrument, elements of said support being a base engaging the base of the instrument, and a pivoted strut interposed between said base and that portion of the support upon which the camera is mounted, substantially as specified.

11. The combination of a pivotally-mounted optical instrument, with a camera movable in the line of its optical axis, and a pivoted and swinging support for said camera having its pivotal axis concentric with the pivotal axis of the instrument, substantially as specified.

12. The combination of a pivotally-mounted optical instrument, with a camera focused for parallel rays and movable in the line of its optical axis, and a pivoted and swinging support for said camera having its pivotal axis concentric with the pivotal axis of the instrument, substantially as specified.

13. The combination of a pivotally-mounted optical instrument, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a pivoted and swinging support for said camera having its pivotal axis concentric with the pivotal axis of the instrument, substantially as specified.

14. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a base engaging the base of the instrument, and a camera-carrying element pivotally mounted upon said base in line with the pivotal axis of the instrument, substantially as specified.

15. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera, comprising a base engaging the base of the instrument, and a camera-carrying element pivotally mounted upon said base in line with the pivotal axis of the instrument, substantially as specified.

16. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, a pivoted and swinging support for said camera having its pivotal axis concentric with that of the instrument, and a strut for bracing said pivotal camera-support when the camera is adjusted for use, substantially as specified.

17. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, a pivoted and swinging support for said camera having its pivotal axis concentric with that of the instrument and a strut for bracing said pivotal camera-support when the camera is adjusted for use, substantially as specified.

18. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, a pivoted and swinging support for said camera having its pivotal axis concentric with that of the instrument and a pivotal strut for bracing said pivotal camera-support when the camera is adjusted for use, substantially as specified.

19. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, a pivoted and swinging support for said camera having its pivotal axis concentric with that of the instrument, and a pivoted strut for bracing said pivotal camera-support when the camera is adjusted for use, substantially as specified.

20. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a base constructed to engage the base of the instrument, a camera-carrying element pivoted to said base in line concentrically with the pivot of the instrument, and a strut interposed between the said camera-carrying element of the support and the base, substantially as specified.

21. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera comprising a base constructed to engage the base of the instrument, a camera-carrying element pivoted to said base in line concentrically with the pivot of the instrument, and a strut interposed between said camera-carrying element of the support and the base, substantially as specified.

22. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a base constructed to engage the base of the instrument, a camera-carrying element pivoted to said base in line concentrically with the pivot of the instrument, and a pivoted strut interposed between the said camera-carrying element of the support and the base, substantially as specified.

23. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera comprising a base constructed to engage the base of the instrument, a camera-carrying element pivoted to said base in line concentrically with the pivot of the instrument, and a pivoted strut interposed between the said camera-carrying element of the support and the base, substantially as specified.

24. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, a support for said camera, and pivotal mountings for said support located on opposite sides of the camera-mounting, and providing pivotal axes for the camera-support concentric with that of the instrument, substantially as specified.

25. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, a support for said camera, and pivotal mountings for said support located on opposite sides of the camera-mounting and providing pivotal axes for the camera-support concentric with that of the instrument, substantially as specified.

26. The combination of an optical instrument having pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a camera-carrying element and a base engaging the base of the instrument and having pivotal bearings for the camera-carrying element concentric with that of the instrument-mounting, said base also having an adjustable member for bearing upon the base of the instrument, substantially as specified.

27. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a camera-carrying element and a base engaging the base of the instrument and having on opposite sides of the latter pivotal bearings for the camera-carrying element which bearings are concentric with that of the instrument-mounting, substantially as specified.

28. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera comprising a camera-carrying element and a base engaging the base of the instrument and having on opposite sides of the latter pivotal bearings for the camera-carrying element, which bearings are concentric with that of the instrument-mounting, substantially as specified.

29. The combination of an optical instrument having pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera detachably mounted in pivotal bearings concentric with those of the instrument-mounting, substantially as specified.

30. The combination of an optical instrument having pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera detachably mounted in pivotal bearings concentric with those of the instrument-mounting, substantially as specified.

31. The combination of an optical instrument having pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a camera-carrying element and a base engaging the base of the instrument, said camera-carrying element being detachably mounted in pivotal bearings on said base, which bearings are concentric with that of the instrument-mounting, substantially as specified.

32. The combination of an optical instrument having pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising the camera-carrying element, a base engaging the base of the instrument and having pivotal bearings for said camera-carrying element which are concentric with the axis of the instrument-mounting, a pivoted strut interposed between the base and said camera-carrying portion of the support, a spring for acting upon said strut and causing it to accommodate itself to the various angular adjustments of said camera-carrying element of the support, and means for locking said strut in its different positions of adjustment, substantially as specified.

33. The combination of an optical instrument having a pivotal mounting, with a camera movable in the line of its optical axis, and a support for said camera comprising a camera-carrying element, a base engaging the base of the instrument and having pivotal bearings for the camera-carrying element concentric with the axis of the instrument-mounting, a pivoted strut interposed between the base and the camera-carrying element of the support, and means for locking said strut in its different positions of adjustment, substantially as specified.

34. The combination of an optical instrument having a pivotal mounting, with a camera focused for parallel rays and movable as a rigid whole in the line of its optical axis, and a support for said camera comprising a camera-carrying element, a base engaging the base of the instrument and having pivotal bearings for the camera-carrying element concentric with the axis of the instrument, a pivoted strut interposed between the base and the camera-carrying element of the support, a spring for acting upon said strut and causing it to accommodate itself to the various angular adjustments of said camera-carrying element of the support, and means for locking said strut in its different positions of adjustment, substantially as specified.

707,423. PROCESS OF OBTAINING ALBUMINOUS SUBSTANCES. ADOLF JOLLES, Vienna, Austria-Hungary. Filed May 29, 1902. Serial No. 109,567. (Specimens.)

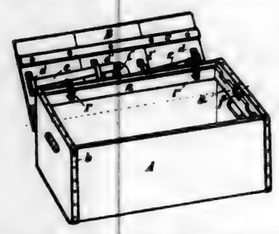
Claim.—1. A process of obtaining an albuminous substance from magma or blood-corpuscles consisting in destroying oxydases in the material, bringing the material to a suitable degree of alkalinity, suitably oxidising the alkalined material, and then suitably precipitating the albumen.

2. A process of obtaining an albuminous substance from magma or blood-corpuscles consisting in destroying the oxydases in the material by the suitable addition thereto of sulfurous acid, then bringing the material to a suitable degree of alkalinity, suitably oxidizing the alkalined material, and then suitably precipitating the albumen.

3. A process of obtaining an albuminous substance from magma or blood-corpuscles, consisting in destroying the oxydases in the material by suitably adding thereto a sulfurous acid, then bringing the material to a suitable degree of alkalinity by the addition thereto of ammonia, suitably oxidizing the alkalined material, and then suitably precipitating the albumen.

4. A process of obtaining an albuminous substance from magma or blood-corpuscles consisting in destroying the oxydases in the material by the addition thereto of sulfurous acid, then bringing the material to a suitable degree of alkalinity by the addition thereto of ammonia, suitably oxidizing the alkalined material by the addition thereto of hydrogen peroxid and the boiling of the mass, and then suitably precipitating the albumen.

707,424. BOX-FASTENER. WILLIAM JORDAN, Winona, Minn. Filed Sept. 27, 1901. Serial No. 76,733. (No model.)



Claim.—1. The combination, with a box-body and its cover, of the fastener described, comprising slidable locking-bars, a countersunk plate let into the cover and provided with stops arranged as shown, and an intermediate raised surface within the sunken portion, a lever-handle arranged in the latter and having a central pin passing through the plate, a spring-washer applied to said pin, a lever below the plate which is pivoted to the locking-bars and provided with a notched boss, and a pin which locks the pin of the lever-handle to said boss, as shown and described.

2. The combination, with the box body and cover, of slidable locking-bars, a recessed plate secured to the upper side of said cover and having a stop and adjacent raised surface in its recessed portion, a lever-handle arranged in the recess of the plate and provided with a pendent pin, a spring-washer applied to said pin, and a lever arranged below the plate, and means for securing it to said handle so that both rotate together, as shown and described.

3. The combination, with the box-body and its cover, of the recessed plate secured in a hole in the cover flush with the surface of the latter, a lever-handle arranged in the recess and having a pin that passes through the plate, a lever arranged under the latter and having a central recess, means for securing the lever to said pin, a washer encircling the handle-pin and arranged in the recess of the lever, and slidable bars connected with the ends of the latter, as shown and described.

4. The combination, with a box-body and its cover, of slidable bars, a lever with which said bars are connected, a lever-handle having a pendent pin, means for securing the lever to said pin, a plate secured to the upper side of the cover and having projections between which the said handle may lie, and a spring-washer which encircles the handle-pin and tends to hold the handle locked between the said projections, as shown and described.

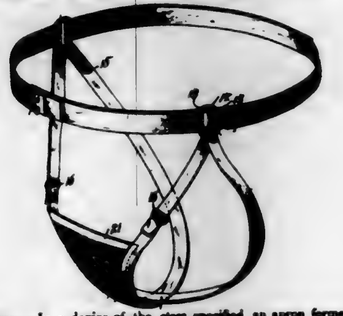
707,425. MANUFACTURE OF PLAYING-BALLS. ELBERT KENDRALL, Boston, Mass. Filed June 23, 1902. Serial No. 112,741. (No model.)

Claim.—1. A process in producing a playing-ball, consisting in winding in miscellaneous directions under high tension upon a center piece a multitude of layers of approximately pure acid-cured sheet-rubber which is drawn by the tension to such thinness that the layers pack together to form a solid body, and applying upon said body under heat and compression a cover of plastic material, the heat and compression being carried to an extent to cause at least the outer layers of rubber to cleave to one another.

2. A process in producing a playing-ball, consisting in winding in miscellaneous directions under high tension upon a center piece a multitude of layers of approximately pure acid-cured sheet-rubber which is drawn by the tension to such thinness that the layers pack together to form a solid body, and applying upon said body under heat and compression a cover of gutta-percha, the heat and compression being carried to an extent to cause at least the outer layers of rubber to cleave to one another and also cause the outer layer of rubber to adhere to the gutta-percha cover.

3. A process in producing a playing-ball, consisting in winding under high tension upon a center piece a multitude of layers of approximately pure acid-cured sheet-rubber which is drawn by the tension to such thinness that the layers pack together to form a solid body, and applying upon said body under heat and great compression a cover of plastic material, and maintaining the compression while the cover cools and hardens.

707,426. COMPRESS. MARX M. KERR, Cincinnati, Ohio. Filed Apr. 10, 1902. Serial No. 102,308. (No model.)



Claim.—In a device of the class specified, an apron formed of a triangular section of netting having reinforced edges, and a supporting device comprising a pair of straps crossing each other at the lower corner of the netting and secured to the opposite edges thereof, said straps having terminal fastening devices at points above the top of the apron, a supporting-belt, adjustable buckles carried by the belt, the straps from each side of the apron at the front of the body extending continuously to the buckle of the belt at the opposite side of the body and thence to the fastening devices above the apron.

707,427. CUFF-HOLDER. WILLIAM C. KEWER, Rochester, N. Y. Filed Aug. 5, 1901. Serial No. 70,977. (No model.)

Claim.—1. A cuff-holder comprising an elongated hollow body formed with an opening, and with parallel flanges near one end, a catch-piece shorter than the body held longitudinally between said flanges, and a transverse pintle in the body piercing the catch-piece, with means for turning the latter on said pintle to engage the body, and a pointed shaft or pin adapted to move longitudinally in the body adjacent to said opening in the latter, substantially as and for the purpose specified.

2. A cuff-holder comprising a hollow body having an opening in its side, a pivotal catch-piece held by said body, a sliding piece or slide adapted to move longitudinally within the body, a pin carried by said slide to cross said opening in the body, and means for actuating the catch-piece, substantially as shown and described.

3. A cuff-holder comprising a hollow body formed with a side opening, a pin adapted to move longitudinally in said body to cross said opening, parallel flanges on the body carrying a transverse pintle, a catch-piece held pivotally on said pintle, and a spring controlled by said pintle, with its extreme ends pressing the catch-piece and said body respectively, substantially as and for the purpose specified.

4. A cuff-holder having a body formed with an opening, a catch-piece held pivotally by said body and adapted to engage the latter, a pin adapted to slide longitudinally within the body adjacent to said opening, and means for turning said catch-piece against the body, the catch-piece and said opening being on opposite sides of the body, substantially as shown and described.

5. A cuff-holder comprising a hollow body formed with an opening, a pivotal catch-piece held by the body, a slide adapted to move longitudinally in said body, a pin carried by the slide to cross said opening in the body, and stops to limit the longitudinal motions of said slide, substantially as set forth.

6. A cuff-holder comprising a hollow body formed with an opening, a pivotal catch-piece held by the body, a slide adapted to move longitudinally in said body, a pin carried by the slide to cross said opening in the body, the slide being bent transversely or doubled with ends of unequal length, the longer one projecting from the body and the other confined within the body, substantially as shown and described.

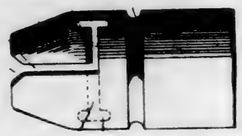
707,428. APPARATUS FOR REMOVING BARK FROM TREES. WELLINGTON P. KINSER, Boston, Mass., assignor, by mesne assignments, to himself, George R. Matthews, and Frank H. Goodyear and Charles W. Goodyear, doing business under the firm-name of F. H. & C. W. Goodyear, Buffalo, N. Y. Filed Nov. 5, 1900. Serial No. 35,562. (No model.)

Claim.—1. In apparatus for removing bark from standing trees, the combination of a tree-engaging, reach-guide support; a reach-guide on said support; a bark-stripper; and a flexible reach attached to said bark-stripper and passing over said guide.

2. In apparatus for removing bark from standing trees, the combination of a pair of independent tree-engaging, reach-guide supports; a reach-guide on each support; a double-ended bark-stripper intermediate said guides; a pair of independent flexible reaches, each attached to the bark-stripper and each passing over a guide.

3. In apparatus for removing bark from trees, a web having a bark-separating edge and a pair of bark-cutters which project forwardly of said web at opposite ends of the web, in combination with a rectangular frame; means for connecting said web to the frame; and a roller journaled in said frame and parallel with said bark-separating edge.

707,429. INSULATOR FOR ELECTRIC WIRES. THEODORE F. KIRK, Nashville, Tenn. Filed Sept. 21, 1901. Serial No. 76,082. (No model.)



Claim.—An insulator having an opening, or slot, extending from its upper end downward, a lateral slot extending outwardly upon opposite sides of the insulator, said lateral slot terminating in a vertical orifice, or bed, for the wire, said orifice extending upwardly and downwardly upon opposite sides of said lateral slot.

707,480. WATCHCASE. RICHARD KUHN, East Orange, N. J., assignor to GUSTAV BUHRE and ERNST BUHRE, New York, N. Y. Filed Mar. 6, 1902. Serial No. 96,949. (No model.)

Claim.—A watchcase, the body portion of which is composed of a single piece of metal, a flange formed therewith and partly inclosing one

side of the same, said flange having countersinks for the movement-fastenings, and the said body portion being adapted for the attachment of a rear plate and a bezel.

707,481. GATE. ANDREW M. LABOR, Paris, Pa. Filed Mar. 17, 1902. Serial No. 98,594. (No model.)

Claim.—1. The combination of a gate, a support on which the same swings, a supplemental support adjacent to the first-mentioned support but separate and distinct therefrom, and a turning connection between the supplemental support and the free or swinging portion of the gate, whereby the front portion of the gate is sustained by the said supplemental support, and the first-mentioned support is relieved of tendency to sag.

2. The combination of a gate, a support on which the same swings, a supplemental support above the first-mentioned support and separate and distinct therefrom, and a longitudinally-compensating, inclined, turning connection between the supplemental support and the free or swinging portion of the gate, said supplemental support and connection sustaining the free front portion of the gate and relieving the first-mentioned support of tendency to sag.

3. The combination of a gate, a support on which the same swings, a supplemental support adjacent to the first-mentioned support but independent thereof, a rope movable over the supplemental support and connected at one end to the free or swinging portion of the gate, and a weight secured to the opposite end of the rope and exerting a constant pull thereon, said weight being of sufficient size to counterbalance the forward or swinging portion of the gate and thereby relieve the support upon which the gate swings of tendency to sag.

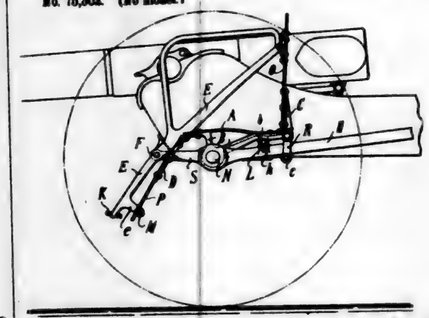
4. The combination of a gate, a post on which the gate swings, a supplemental post adjacent to the first-mentioned post but separate and distinct therefrom, a pulley in said supplemental post and a second pulley at the rear thereof, a line extending over said pulleys and at its forward end connected to the swinging portion of the gate, and a weight on the opposite end of the line.

5. The combination of a swinging gate, a support at the hinged end of the gate, a weighted rope movable over the support and connected to the gate, a vertically-oscillating latch on the gate, an upwardly-extending lever adapted to oscillate laterally on the latch, the upper end of said lever being connected to the said rope, and means for exerting lateral pull on the rope.

6. The combination of a swinging gate including a gate-post, posts 14, 15 and 16 at one side of the roadway and substantially in line with the gate-post, the gate being adapted to open against post 14, rope 26 extending from the gate to post 15, rope 27 extending from the gate to post 14 and from thence to post 16, gate latch mechanism, and an operative connection between the same and the gate ends of ropes 26 and 27.

7. The combination of a swinging gate including a gate-post, post 14 against which the gate opens, a gravity-latch on post 14 adapted to automatically engage the gate and hold it open, longitudinally-movable rod 30, and a cam device on said rod adapted to be moved thereby beneath and elevate the gravity-latch.

707,482. COMBINED AXLE-SEAT AND SHIELD FOR GUN-CARRIAGES. OTTO LAUBER and FRIEDRICH STOCK, Essen, Germany, assignors to Fried. Krupp, Essen, Germany. Filed Sept. 13, 1901. Serial No. 75,302. (No model.)



Claim.—1. In a wheeled gun-carriage, the combination with a plate revoluble on the carriage, of plates permanently hinged at their inner ends to said revoluble plate, and means locking the plates either in a bent position to form a seat or in a nearly-extended position to form a shield, substantially as specified.

2. In wheeled gun-carriages the combination of a seat-plate revoluble on the carriage, a back plate hinged to said seat-plate, arm-supports hinged to the back plate and to the carriage, the seat, back, arm-supports and carriage forming a jointed quadrangle, and means for rigidly connecting two adjacent sides of the jointed quadrangle, both in the bent and nearly-extended position of the seat and back plate, substantially as specified.

3. In wheeled gun-carriages the combination of a seat-plate revoluble on the carriage, a back plate hinged to said seat-plate, arm-supports hinged to the back plate and to the carriage, a leg-support plate hinged to the seat-plate and having sliding connection with the arm-supports, the seat, back, arm-supports and carriage forming a jointed quadrangle, and means for rigidly connecting two adjacent sides of the jointed quadrangle, both in the bent and in the nearly-extended position of the seat, back and leg-support plate, substantially as specified.

707,438. SHADE-SUPPORT. ERNEST A. LIVET, London, England, assignor to the Hiram Maxim Lamp Company, Limited, London, England. Filed Mar. 19, 1901. Serial No. 51,691. (No model.)

Claim.—1. The herein-described means for directly and detachably affixing a shade, reflector, or screen to an electric-lamp bulb, said means consisting of longitudinally-extensible helical springs attached in tension and in one place to the shade, reflector or screen, and occupying therein the position of the sides of an inscribed regular polygon, so as to be capable of being stretched and deflected in order to pass over the part of the bulb of greatest diameter, and of contracting about the neck of the bulb so as to retain the shade, reflector or screen in position thereon, substantially, as specified.

2. The combination with means for attaching a shade, reflector, or screen to an electric-lamp bulb consisting of spiral springs distended in the form of a regular polygon and carried by the shade, reflector or screen, of means of steadying the latter consisting of an eye carried by the shade, reflector or screen and adapted to receive the sealing-off point of the bulb, substantially, as specified.

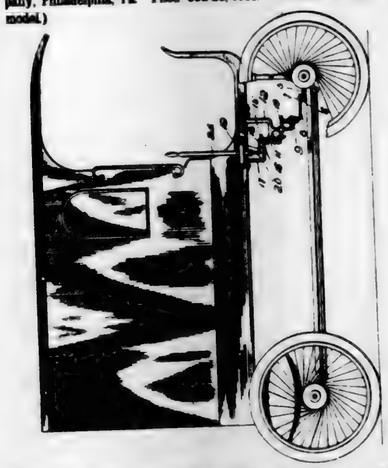
3. The combination with a shade reflector or screen for electric lamps, of spiral springs carried by the shade reflector or screen and distended in the form of a polygon so as to be capable of being stretched or deflected in order to pass over the part of the bulb of greatest diameter and of contracting about the neck of the bulb, as set forth.

707,484. PROCESS OF MAKING PIGMENTS. JOSEPH LOWES Smethwick, England, assignor of two-thirds to Jabez Lowes and Edward Holden, Smethwick, England. Filed Dec. 5, 1901. Serial No. 84,616. (No specimens.)

Claim.—1. A process of manufacturing white pigments from zinc ores which consists in converting the ore into crude zinc oxid, suitably dissolving the oxid to form a solution of acetate of zinc, precipitating from the said solution any lead which may be contained therein, crystallizing out of the solution zinc acetate, suitably dissolving the crystals, precipitating from the said solution zinc sulfid, and then suitably treating the zinc sulfid to form a pigment.

2. A process of manufacturing white pigments from ores or compounds containing zinc which consists in heating the zinc ore so as to convert it into crude zinc oxid, dissolving the said zinc oxid in strong hot acetate acid so as to form a solution of acetate of zinc, then precipitating from the clear liquid any lead which the zinc ore may have contained and which the acetate acid may have dissolved, by the addition to the solution of sheet-zinc, crystallizing out of the solution zinc acetate, dissolving the crystals in water, passing sulfureted hydrogen into the solution thereby precipitating the zinc as zinc sulfid and then treating the zinc sulfid with free sulfur out of contact with air forming thereby a white pigment.

707,485. STEERING-GEAR FOR AUTOMOBILES. JOHN G. MACPHERSON, Philadelphia, Pa., assignor to MacPherson Automobile Company, Philadelphia, Pa. Filed Oct. 28, 1901. Serial No. 80,120. (No model.)

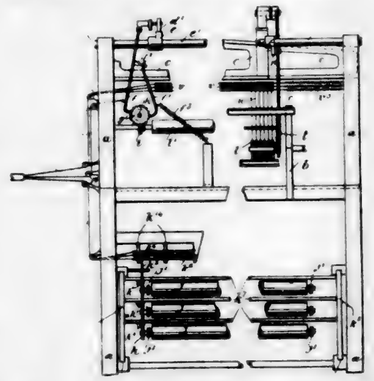


Claim.—1. In combination with a vehicle, of a steering-gear therefor comprising a hand-lever, a bell-crank lever operated thereby, a segmental gear operated by said bell-crank lever, a vertical shaft, a gear carried thereby and meshing with said segmental gear, a worm-gear operated by said shaft, a large gear meshing with said worm-gear, and means operated by said large gear to steer the front wheels of the vehicle.

2. In combination with a vehicle of a steering-gear therefor comprising a hand-lever, a bell-crank lever operated thereby, a segmental gear operated by said bell-crank lever, a vertical shaft, a gear carried thereby and meshing with said segmental gear, a worm-gear operated by said shaft, a large gear meshing with said worm-gear, a rod or arm connected to said large gear, and means connected to said arm for steering the front wheels of the vehicle.

3. In combination with a vehicle of a steering-gear therefor comprising a hand-lever, a bell-crank lever operated thereby, a segmental gear operated by said bell-crank lever, a vertical shaft, a gear carried thereby and meshing with said segmental gear, a worm-gear operated by said shaft, a large gear meshing with said worm-gear, a rod or arm connected to said large gear, a connecting-rod connected to said arm, and levers carried by the front wheels' axles connected to the connecting-rod so as to be moved in unison.

707,486. LACE-MACHINE. CHARLES MARTIN, Nottingham, England. Filed Nov. 17, 1900. Serial No. 36,900. (No model.)



Claim.—1. In a lace-machine, the combination of devices for turning the work-beam in either direction, devices for turning the warp-beams in a backward direction, a jacquard for controlling said devices, and means for partially rotating the bobbins to take up slack threads, substantially as described.

2. In a lace-machine, the combination of the lace-beam, a worm-wheel thereon, a worm, worm-spindle, a pair of clawkers for turning said wheels in opposite directions, a spring for drawing one of said clawkers into engagement with its ratchet, and jacquard mechanism for disengaging said clawkers and bringing the other one into action at the proper times, substantially as described.

3. In a lace-machine, the combination of the warp-beams, ratchet-wheels at the ends of said beams, pawls engaging said ratchet-wheels, and jacquard mechanism for controlling the engagement of said pawls, substantially as described.

4. In a lace-machine, the combination of the warp-beams, beam-arms carrying the same, ratchet-wheels on said beams, pawls engaging said ratchet-wheels, means for connecting said pawls with spring-controlled sliding plates, and jacquard mechanism for operating said sliding plates, substantially as described.

5. In a lace-machine, the combination of the bobbins, the bobbin-carriers, pivoted grippers adapted to clip the edges of said bobbins, means for reciprocating said grippers, and jacquard mechanism for causing said grippers to act on the bobbins, substantially as described.

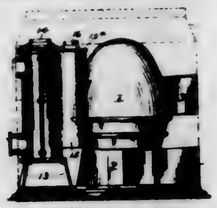
6. In a lace-machine, the combination of the bobbins, the bobbin-carriers, a catch-bar therefor, teeth on said catch-bar for properly spacing said bobbins, spring-grippers for engaging said bobbins above their centers, and means for operating said grippers, substantially as described.

7. In a lace-machine, the combination of the bobbins, grippers for engaging the same having bifurcated spring ends, a carrier-bar in which said grippers are pivoted, mechanism for reciprocating said carrier-bar from the main cam-shaft of the machine, jacquard wires connected to said grippers, spring-controlled sliding plates to which said wires are connected, and jacquard mechanism for operating said plates, substantially as described.

707,487. HOT-AIR FURNACE. THOMAS J. MARCH, Pottstown, Pa. Filed Feb. 5, 1902. Serial No. 92,729. (No model.)

Claim.—1. In a furnace, the combination with a combustion-cham-

ber, of a series of hot-air tubes abutting against the combustion-chamber and open at their lower ends, a plate covering the upper ends of said hot-air chambers, and means on said plate for the direct connection with said chambers of hot-air-circulating flues.

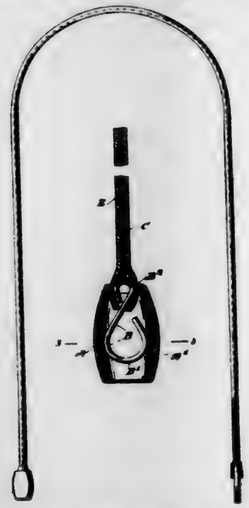


2. In a furnace, the combination with a combustion-chamber and a drum located a short distance from and communicating with said combustion-chamber, of hot-air chambers located between and abutting against the combustion-chamber and said drum, said chambers open at their lower ends, means at the upper ends of said chambers for the direct attachment of hot-air flues, a sleeve or tube extending through the said drum and open at both ends, and means at the upper end of said sleeve or tube for the direct attachment of a hot-air flue.

3. In a furnace, the combination with a furnace-casing and a combustion-chamber therein, of a drum located near the combustion-chamber and communicating therewith, a sleeve or tube open at its ends and located in said drum, said sleeve having flaring ends closing the ends of the chamber between said sleeve or tube and the wall of the drum, a cap on the upper end of said drum, communicating with the sleeve or tube and means on said cap for the direct attachment of a hot-air flue.

4. In a furnace, the combination with a combustion-chamber and an inclosing casing, of a sleeve forming a hot-air chamber, an annular chamber inclosing the sleeve and having an inlet and an outlet at its upper end on opposite sides thereof, a partition or partitions projecting down a proper distance into said annular chamber, a flue connecting the inlet of said annular chamber with the combustion-chamber, and a funneled cap on said sleeve adapted to be connected with a hot-air flue.

707,438. MEDICAL ELECTRODE. GEORGE G. MARSHALL, Wallingford, Vt. Filed May 2, 1902. Serial No. 105,630. (No model.)



Claim.—1. An electrode comprising a cap of non-conducting material, having a passage from one end of the cap to the other, and a metallic conductor held in the said cap and adapted to pass into the said passage at the large end thereof, and held against outward movement through the small end of the passage by the sides of the conductor engaging the side walls of the passage between the ends, as set forth.

2. An electrode comprising a cap of non-conducting material and having a tapering opening or passage, and a metallic conductor held in the said cap and engaging the walls of the passage at the widest portion thereof, as set forth.

3. An electrode comprising a cap having an opening or passage lengthwise through the cap, and a conductor removably held in the said passage, as set forth.

4. An electrode comprising a cap of non-conducting material, formed with an opening or passage contracted at one end, and a conductor in the cap, engaging the walls of the passage, the reduced outer end of the said conductor extending through an end opening of the cap, as set forth.

5. An electrode comprising a cap of non-conducting material, formed with a tapering opening, and a conductor in the form of a tapering metallic plate, engaging the side walls of the opening, between the ends of the opening, as set forth.

6. An electrode comprising a cap of non-conducting material, formed with a tapering opening, and a conductor in the form of a tapering metallic plate, engaging the side walls of the opening, between the ends of the opening, the plate having a shank and a nut screwing thereon and seated on the cap at the reduced end of the opening, as set forth.

707,439. CARRIAGE-POLE ATTACHMENT. PATRICK MASTERSON, Newington, Canada. Filed Feb. 8, 1902. Serial No. 93,194. (No model.)

Claim.—1. The combination with the pole and cross-arm, of a pair of converging draw-rods having suitable sockets at their rear ends, braces secured at their front ends to said pole and formed with enlarged portions at their rear ends, said enlarged portions being bent to form guideways for said draw-rods, means for securing the outer ends of said braces to said cross-arm, and means for securing said draw-rods adjustably in said guideways as and for the purpose specified.

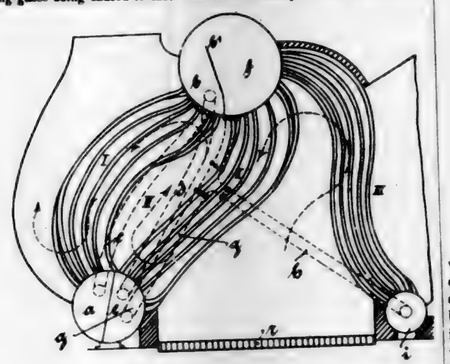
2. The combination with the pole and cross-arm of a pair of draw-rods having suitable sockets at their rear ends, braces secured at their front ends to said pole and formed at their rear ends with enlarged portions said enlarged portions being bent to form guideways for said draw-rods, and flat portions to overlap said cross-arm, screws or bolts passing through said flat portions and said cross-piece and set-screws extending through said enlarged portion of the braces to hold said adjustable draw-rods in position as and for the purpose specified.

3. The combination with the pole and cross-arm, of a pair of adjustable draw-rods having recesses formed therein, the distance of each of said recesses on one rod from the end of its rod, being equal to the distance of a corresponding recess on the other rod from the end of its rod, braces secured at their front ends to said pole and formed with enlarged portions at their outer ends, said enlarged portions being bent to form guideways for said draw-rods and flat portions to overlap said cross-arm, screws or bolts to secure said flat portions to said cross-arm and set-screws extending through said enlarged portion and engaging the recesses in said draw-rods as and for the purpose specified.

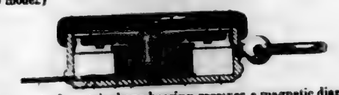
707,440. WATER-TUBE STEAM-BOILER. ALFRED MEILBORN, Dietrichsdorf, Germany. Filed Mar. 28, 1902. Serial No. 100,467. (No model.)

Claim.—1. In a steam-generator, the combination with lower drums or compartments *a*, *e*, *i*, and upper drums or compartments *b*, *f*, of a series of heating-tubes I, connecting the compartments *a*, *b*, a series of heating-tubes II connecting the compartments *e*, *f*, a series of heating-tubes III connecting the compartments *f*, *i*; pipes *c*, *d*, connecting compartments *a*, *e*, with compartment *b*; pipe *g* connecting compartments *e*, *f*, and pipe *h* connecting the compartment *i* and pipe *g*, the various series of heating-tubes being so arranged that the series III will be acted upon first by the heating-gases, and the other series II, I, in succession thereafter and said heating-gases caused to take a direction contrary to that of the water.

2. In a steam-generator, the combination with the masonry, of lower drums or compartments *a*, *e*, *i*, and upper drums or compartments *b*, *f*, arranged within the space inclosed by the masonry, a series of heating-tubes I connecting the compartments *a*, *b*, a series of heating-tubes II connecting the compartments *e*, *f*, a series of heating-tubes III connecting the compartments *f*, *i*; pipes *c*, *d*, connecting compartments *a*, *e*, with compartment *b*; pipe *g*, connecting compartments *e*, *f*, and pipe *h* connecting the compartment *i* and pipe *g*, said pipes *c*, *d*, *g*, *h*, being arranged outside of the masonry, the various series of heating-tubes I, II, III, being so arranged that the series III will be acted upon first by the heating-gases, and the other series II I in succession thereafter, and said heating-gases being caused to take a direction contrary to that of the water.



707,441. TELEPHONE-RECEIVER. LEMUEL MELLETT, Somerville, Mass., assignor to the American Otophone Company, Boston, Mass., a Corporation of Maine. Filed July 5, 1901. Serial No. 67,080. (No model.)



Claim.—1. In a telephone hearing-receiver, a magnetic diaphragm, electromagnetic means exerting attraction on said diaphragm, the receiver being provided with such means on one side only of the diaphragm, spring means exerting an outward pressure on the diaphragm in opposition to the magnetic attraction, and spring means exerting inward pressure on the diaphragm in opposition to the pressure of the first said spring means, substantially as and for the purpose described.

2. In a telephone hearing-receiver, a magnetic diaphragm free at its edges, a magnet coöperating with the diaphragm on one side thereof and springs acting in opposition to each other on the diaphragm.

3. In a telephone hearing-receiver, a magnetic diaphragm, a magnet coöperating with said diaphragm on one side thereof, a spring on the inner side of the diaphragm acting in opposition to the attraction of the magnet, a spring on the outer side of the diaphragm acting in opposition to the first said spring, and an apertured cover for the outer side of the diaphragm forming an outer support for the last said spring.

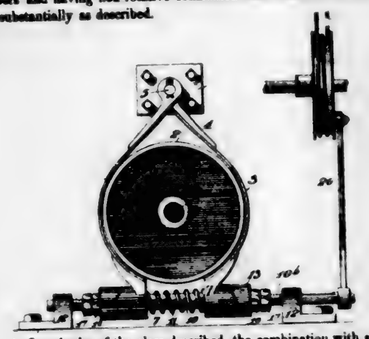
4. In a telephone-receiver, a diaphragm, a magnet operating behind the diaphragm to directly vibrate the same, and a series of differently-tuned harmonic vibrators located behind the diaphragm.

707,442. BRAKE FOR MOTOR-SHAFTS OF ELEVATORS. EDWARD W. MOOR, St. Louis, Mo. Filed Mar. 7, 1902. Serial No. 97,102. (No model.)

Claim.—1. In a brake of the class described, the combination with a brake-wheel, of a pair of brake-straps located at the rim of said wheel, a rock-shaft, a pair of inner cam members having connection with said brake-straps and through which said rock-shaft passes, and a pair of outer cam members non-rotatably mounted on said rock-shaft and arranged in engagement with said inner cam members, substantially as described.

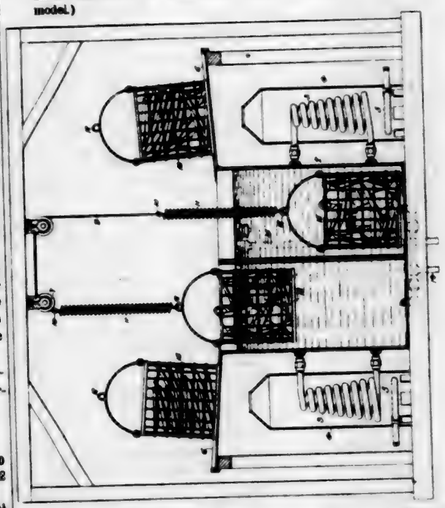
2. In a brake of the class described, the combination with a brake-wheel, of a pair of brake-straps located at the rim of said wheel, a rock-shaft, a pair of inner cam members having connection with said brake-straps and through which said rock-shaft passes, a pair of outer cam members non-rotatably mounted on said rock-shaft and arranged in engagement with said inner cam members, and an expansible spring located between said inner cam members, substantially as described.

3. In a brake of the class described, the combination with a brake-wheel, of a pair of brake-straps located at the rim of said wheel, a pair of inner cam members having inclined faces and connected to said brake-straps, a spring located between said inner cam members, outer cam members having inclined faces arranged to engage the inclined faces of said inner cam members, and a rock-shaft passing loosely through said inner cam members and having non-rotative connection with said outer cam members, substantially as described.



4. In a brake of the class described, the combination with a brake-wheel, of a pair of brake-straps located at the rim of said wheel, a pair of inner cam members having inclined faces and connected to said brake-straps, a spring located between said inner cam members, outer cam members having inclined faces arranged to engage the inclined faces of said inner cam members, a rock-shaft passing loosely through said inner cam members and having non-rotative connection with said outer cam members, and means on said rock-shaft for adjusting said outer cam members to said inner cam members, substantially as described.

707,448. DISH-WASHING APPARATUS. JOSEPH D. MORLEY, Lake Pleasant, N. Y. Filed Dec. 14, 1901. Serial No. 85,906. (No model.)



Claim.—1. The combination in dish-washing apparatus, of a tank for containing wash-water, a dish-receptacle movable up and down in said tank, and a reciprocable suspension device for said receptacle having as one of its elements a vertically expansible and contractible spring, substantially as specified.

2. The combination in dish-washing apparatus, of a tank for containing wash-water, a circular dish-receptacle movable up and down in said tank, and a supporting device from which said receptacle is suspended by means of an eye, whereby it is free to turn back and forth, said suspension device being also susceptible of up-and-down movement, substantially as specified.

3. The combination in dish-washing apparatus, of a tank for containing wash-water, a dish-receptacle movable up and down in said tank, and a suspension device on which said receptacle is mounted so as to be free to turn back and forth, said suspension device being also susceptible

of up-and-down movement, and having as an element a spring capable of expanding and contracting vertically, substantially as specified.

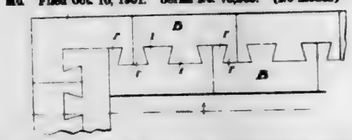
4. The combination in dish-washing apparatus, of a pair of tanks located side by side, one for containing wash-water and the other for containing rinse-water, a pair of dish-receptacles, one in each tank, and a suspension device extending from one dish-receptacle to the other, whereby one is caused to counterbalance the other, and up-and-down movements of the receptacle can be readily effected by hand, substantially as specified.

5. The combination in dish-washing apparatus, of a pair of tanks located side by side, one for containing wash-water and the other for rinse-water, a pair of dish-receptacles one in each tank, a pair of pulleys located one above each tank and a flexible connection passing over said pulleys and having a dish-receptacle suspended from each end, substantially as specified.

6. The combination in dish-washing apparatus, of a pair of tanks located side by side, one for containing wash-water and the other for rinse-water, a pair of dish-receptacles one in each tank, a pair of pulleys located one above each tank and a flexible connection passing over said pulleys and having a dish-receptacle suspended from each end by means of a coiled spring, substantially as specified.

7. The combination in dish-washing apparatus, of a pair of tanks disposed side by side, one for containing wash-water and the other for containing rinse-water, a pair of dish-receptacles one in each tank, a pair of pulleys located one above each tank, and a flexible connection passing over said pulleys and having a dish-receptacle suspended from each end of it, said flexible connection having enlargements whereby its movement over the pulleys is restricted, substantially as specified.

707,444. MASONRY WALL AND BRICKS FOR SAME. ALFRED H. MOSES, St. Louis, Mo., assignor to J. H. Moses & Co., St. Louis, Mo. Filed Oct. 10, 1901. Serial No. 78,263. (No model.)



Claim.—1. In a wall, a brick having a series of tongues and grooves disposed on one of the vertical faces thereof, and suitable marginal grooves for "pointing" purposes, substantially as set forth.

2. A wall composed of a series of layers or courses interlocking along their vertical faces with a similar adjacent series, the individual bricks being provided with alining openings disposed parallel to each interlocking face and collectively forming flues through the completed wall, substantially as set forth.

3. A wall composed of a series of layers or courses of brick, a second adjacent and similar series, and keys disposed in different planes from said courses for locking the series together, substantially as set forth.

4. In a wall, a brick having a series of tongues and grooves disposed on one of the vertical faces thereof, a series of marginal grooves along the opposite vertical face, and an additional dovetail groove disposed along the face of the brick, substantially as set forth.

5. In a wall having a series of interlocking and overlapping bricks, a corner-brick having its faces disposed at an angle to one another, and having a groove on the inner face of one member thereof, said groove being adapted to receive the adjacent ends of the abutting bricks located at the corner of the wall, substantially as set forth.

6. In a wall, a corner-brick having its faces disposed at an angle to one another and having grooves disposed along the inner faces of its respective members adapted to interlock simultaneously with corresponding tongues of the adjacent bricks of two courses of the walls meeting at such corner, substantially as set forth.

7. A wall comprising a series of overlapping bricks interlocking with one another by tongues and grooves disposed along the vertical faces of the bricks, in combination with corner-bricks, one member of each of which is provided with a groove on the inner face thereof for the reception of the adjacent ends of the abutting bricks located at the corner of the wall, substantially as set forth.

8. In a wall, a brick having a dovetail groove disposed on one of the vertical faces thereof, terminal fractional tongues forming the outer bounding walls of the groove, and a tongue or lug projecting from one end of the brick adapted to lock with the vertical member of a window-frame, substantially as set forth.

707,445. INHALER. JOHN H. MCCULLOCH, Sewerville, Pa. Filed Apr. 10, 1902. Serial No. 102,310. (No model.)

Claim.—1. A medicator, comprising parallel side nasal tubes, and a mouth-tube communicating therewith and rotating upon an axis transverse to the side tubes, whereby said mouth-tube may be folded to lie in the same plane with the side tubes; substantially as described.

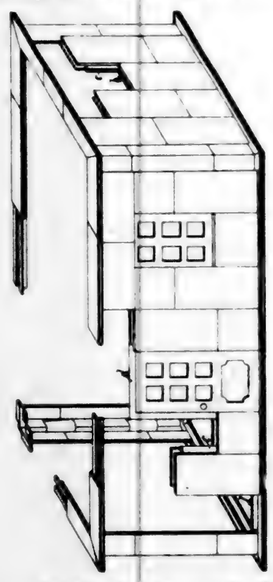
2. A medicator, comprising parallel side nasal tubes, and an intermediate mouthpiece having transverse oppositely-projecting tubes, communicating with and pivotally attached to the side tubes; substantially as described.

3. A medicator, comprising parallel side nasal tubes with projecting lower portions, and a mouth-tube having projecting lower portions adapted to rotatably engage the said projecting lower portions; substantially as described.

4. A medicator, comprising parallel side nasal tubes, elbows to which the same are attached, a mouth-tube having projecting lower portions pivotally attached to said elbows; substantially as described.

5. A medicator, comprising parallel side nasal tubes having projecting lower portions with a peripheral opening, and a mouth-tube, having projections rotatably secured to said projecting lower portions, and having a peripheral opening registering with the peripheral opening in the projecting lower portion of the nasal tube; substantially as described.

707,446. BOX OF BUILDING MATERIAL. OTTO NESTWIG, Neustadt, Germany. Filed Sept. 5, 1901. Serial No. 74,447. (No model.)

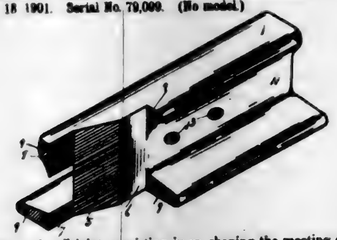


Claim.—1. Toy building-blocks representing wall-surfaces, doors, windows, and roof-covering having tongues and grooves on their respective edges, in combination with T-shaped strips, whose stem or tongue portion is adapted to fit the grooves of the said blocks and hold them in line, substantially as and for the purposes set forth.

2. Toy building-blocks representing wall-surfaces, doors, windows, and roof-covering having tongues and grooves, in combination with T-shaped strips, whose stem or tongue portion is adapted to fit the grooves of the said blocks and hold them in line, of channeled bars adapted to slide over the flange portion of the T-shaped strip and rigidly tie the same together, substantially as and for the purposes set forth.

3. Toy building-blocks representing wall-surfaces, doors, windows, and roof-coverings having tongues and grooves, in combination with corner-blocks provided with hollow tongues adapted to fit the grooves of the said building-blocks and hold them in line vertically, and splice-plates fitting the said hollow tongues of the corner-blocks, substantially as and for the purposes set forth.

707,447. RAIL-JOINT. DANIEL H. NOBLE, Sheridan, Mont. Filed Oct. 18 1901. Serial No. 79,099. (No model.)



Claim.—A rail-joint consisting in so shaping the meeting ends of each rail that each end will be provided with an obliquely-disposed surface 5 in its central or rib portion, each rail also having the longitudinally-disposed surfaces 6, 7 and 8 paralleling each other, each rail being further provided with the transversely-disposed surfaces 9, said parts on each rail being parallel with the parts on the other rail all substantially as specified and for the purpose set forth.

707,448. WATER DISTRIBUTION. WESLEY O'NEILL and WILLIAM H. GORDON, Russellville, Pa. Filed June 24, 1901. Serial No. 65,734. (No model.)

Claim.—1. The combination with the tank A; of the water-supply pipe C; the valve-casing D, fixed in communication with said supply-pipe, and provided with the main port D'; the lever fulcrumed on said casing; the valve-head D^2, upon said lever arranged to register with said port D'; the vent-port d^3, in said lever; the pipe D^3, connecting said port d^3, with the atmosphere; and the flexible connectors E, E', operatively attached to said pipe D^3, upon the opposite sides thereof, substantially as set forth.

2. In a valve, the combination with a casing provided with a main port; of a bracket-arm projecting from said casing; a lever fulcrumed in said bracket-arm; a valve-head upon said lever arranged to register with said main port; a vent-port extending through said valve-head and lever, in communication with the atmosphere; and flexible connectors attached to the opposite sides of said vent-pipe, substantially as set forth.

3. In a valve, the combination with a casing provided with a main port; of a bracket-arm projecting from said casing; a lever fulcrumed in said bracket-arm; a valve-head upon said lever arranged to register with said main port; a vent-port extending through said valve-head and lever, in communication with the atmosphere; and an abutment fixed upon said casing to limit the motion of said valve-head with respect to said main port, substantially as set forth.

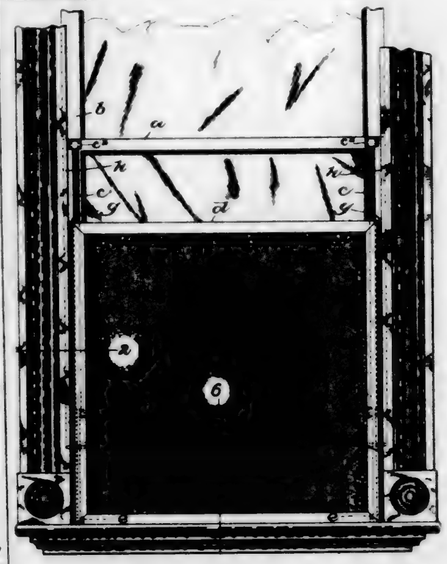
4. In a valve, the combination with a casing provided with a main port; of a bracket-arm projecting from said casing; a lever fulcrumed in said bracket-arm; a valve-head upon said lever arranged to register with said main port; a vent-port extending through said valve-head and lever, in communication with the atmosphere; an abutment fixed upon the bracket-arm of said casing, arranged to limit the motion of said valve-head with respect to said main port; and guides upon said valve-casing for said valve-head, substantially as set forth.

707,449. WINDOW-SCREEN. OVIDE OUELLETTE, Lowell, Mass. Filed Dec. 5, 1901. Serial No. 84,776. (No model.)

Claim.—1. A window-sash having screen-guides on its inner side, and a screen having runners engaged frictionally with said guides, whereby the screen may be raised and lowered either with the sash or independently thereof.

2. A window-sash having screen-guides on its inner side, a screen having runners engaged with said guides, and adapted to be raised or lowered either with the sash or independently thereof, and a flexible continuous inwardly-projecting guard on the bottom rail of the sash, formed to bear yieldingly on the outer side of the screen.

3. A window-sash having screen-guides on its inner side, a screen having runners engaged with said guides, and flexible guards on the edges of the screen, formed to bear on the window-casing.

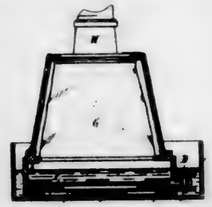


4. A window-sash having screen-guides on its inner side, a screen having runners engaged frictionally with said guides, and flexible guards on the bottom rail of the sash, formed to bear yieldingly on the outer side of the screen, and flexible guards on the edges of the screen, formed to bear on the window-casing.

5. A window-sash having slots in the bottom of its lower rail, detents on the top of its meeting-rail, and sash-guides having boot ears at their lower ends formed to enter said slots, and spring-hooks at their upper ends formed to spring into engagement with said detents.

6. A window-sash having screen-guides on its inner side, and a screen having runners engaged with said slides, said runners having hooks at their ends adapted to detachably engage the upper and lower ends of the screen.

707,450. PHOTOGRAPHIC DEVELOPING APPARATUS. EMILE REMAILHO, Paris, France. Filed Nov. 15, 1897. Serial No. 658,553. (No model.)



Claim.—1. A holder for use in developing photographic negatives in full daylight, comprising a frame provided with a closable opening to admit a photographic plate and having passages arranged to admit liquid from the exterior of the frame to the interior thereof and at the same time prevent light from entering within the frame, a dark chamber combined with said frame and having a closable inspection-aperture at the end opposite to the frame and a non-actinic glass plate forming the bottom of the frame and secured in grooves therein, substantially as set forth.

2. A holder for use in developing photographic negatives in full daylight, comprising a frame with a closable opening through which a photographic plate is adapted to be inserted and having passages arranged to admit liquid from the exterior of the frame to the interior thereof and at the same time prevent light from entering within the frame, means for sealing said closable opening against the admission of light after the photographic plate has been inserted and a non-actinic glass plate forming the bottom of the frame and secured in grooves in the latter, substantially as set forth.

3. A holder for use in developing photographic negatives in full

daylight, comprising a frame having passages arranged to admit liquid from the exterior of the frame to the interior thereof and at the same time prevent light from entering within the frame, a projection on the frame having an opening through which the plate is adapted to be inserted, a plug having a slot to correspond to the width and thickness of the plate and adapted to register with an opening in the projection, and a non-actinic glass plate forming the bottom of the frame and secured in grooves in the latter, substantially as set forth.

4. A holder for use in developing photographic negatives in full daylight, comprising a frame with a closable opening to admit a photographic plate and having passages arranged to admit liquid from the exterior of the frame to the interior thereof and at the same time prevent light from entering within the frame, and a non-actinic glass plate forming the bottom of the frame and secured in grooves in the latter, in combination with a second frame into which the first frame is adapted to be placed, and a receptacle M carried by said second frame, all as and for the purposes specified.

5. A holder for use in developing photographic negatives in full daylight, comprising a frame with a closable opening to admit a photographic plate and having passages arranged to admit liquid from the exterior of the frame to the interior thereof and at the same time prevent light from entering within the frame, and a non-actinic glass plate forming the bottom of the frame and secured in grooves in the latter, in combination with a second frame into which the first frame is adapted to be placed and means for detachably securing the two frames together.

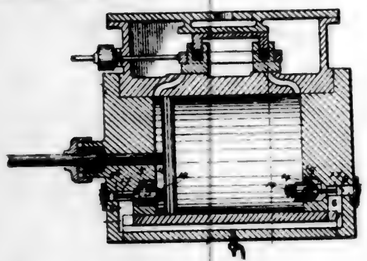
707,451. FOLDING UMBRELLA. ADAM SCHAEFER and FREDERICK SCHAEFER, Williamsport, Pa. Filed Feb. 23, 1903. Serial No. 96,161. (No model.)

Claim.—1. A folding umbrella, comprising a stick composed of an outer and an inner tubular member, a tubular cap-piece fixedly secured upon the upper end of the outer tubular member, extensible ribs pivotally secured to said cap-piece, the inner and outer tubular members each including an upper and a lower section, the lower sections of the said inner and outer tubular members being fixedly connected, the two sections of the inner member having a hinged joint, the upper section of the outer member with its attached cap being slidable upon the upper end of the inner tubular member, whereby to project above the tip end of the stick when the parts are folded, the cover secured to the cap, a single runner slidable on the stick, the braces joined with the said runner and the extensible ribs, and spring-actuated detents, one on the upper and one on the lower end of the stick for coöperating with the single runner, all being arranged substantially as shown and for the purposes described.

2. A foldable umbrella, comprising in combination, a stick consisting of an outer tubular member, formed of an upper and a lower section a single runner slidable upon the stick, a detent on the lower section for engaging with the runner when the latter is pulled down, a tubular cap-piece fixedly mounted on the upper end of the outer tubular member, the other section of said outer tubular member having an upper slot 18 and a lower slot 18ª, an inner tubular member slidable within the outer tubular member, and composed of an upper and a lower section, the two sections being hinged together, and the lower section fixedly joined with the lower section of the outer tubular member, a spring-detent mounted on the upper section of the said inner member, adapted to project through the slot 18 of the outer member, when the inner and outer members are adjusted in vertical alinement, a spring-detent on the lower section of the inner member, adapted to engage the slot 18 of the outer member, and lock the lower section of the inner member with the upper section of the outer member, whereby to hold the inner and outer stick portions from movement upon each other, said detents being arranged to automatically extend within the tubular member when the stick portions are adjusted to their folded position, the extensible ribs secured to the tubular cap-piece, the cover secured to said cap and ribs, and the brace secured to the single runner and the ribs, all being arranged substantially as shown and for the purposes described.

707,452. VALVE-MOTION. GEORGE M. SEWELL, Birmingham, Ala. Filed Oct. 9, 1901. Serial No. 77,975. (No model.)

Claim.—1. The combination with the cylinder, cylinder-heads, inclosed piston-head, exhaust-recesses in the inner faces of said cylinder heads, having valve-seats, exhaust-valves working in said recesses, coiled springs attached to the front ends of said valves, stems secured to the valves, cross-heads attached to the valve-stems, connecting-rods secured to the cross-heads, cavities or grooves in the outer faces of the cylinder-heads adapted to receive the cross-heads, passages leading from the exhaust-recesses in the cylinder-heads through the same, a jacket or casing partly or wholly inclosing the steam-cylinder, said casing inclosing an exhaust-steam-cylinder heating-space, having communication with exhaust-passages in the cylinder-heads, an opening in said jacket or casing communicating with the atmosphere or condenser, and means for alternately admitting live steam to each end of the cylinder, substantially as shown and described.



2. The combination with a steam-cylinder having cylinder-heads and inclosed piston, of exhaust recesses or cavities in the cylinder-heads, valve-seats in the said exhaust-recesses, scallops or pockets adjacent to and surrounding said valve-seats, exhaust-valves comprising a head, coiled springs secured to the head of said exhaust-valves and projecting forwardly therefrom, a stem projecting rearwardly from the valve-heads, cross-heads secured to the valve-stems, a cavity or groove in the rear face of each cylinder-head, adapted to receive the cross-heads, passages leading from the exhaust-recesses, downwardly and forwardly through the cylinder-heads, exhaust-steam spaces surrounding the cylinder and communicating with the exhaust-passages, rods connecting the cross-heads of the exhaust-valves, said rods passing through the cylinder-heads and within the exhaust-steam space surrounding the cylinder, and means substantially as described for admitting steam alternately to the ends of the cylinder.

3. In a steam-engine, the combination with a cylinder and cylinder-heads, exhaust-recesses in said heads, passages leading from the recesses through the cylinder-heads, valve-seats in said recesses, scallops or pockets adjacent to and surrounding said valve-seats, and an inclosed piston, of exhaust-valves adapted to be seated in said valve-seats, and each having rearwardly-extending stem, cross-heads attached to the stems, and rods connecting the said cross-heads, whereby the valves are adapted to be alternately opened and closed by the impact of the piston against the faces of said valves.

4. A steam-engine comprising a cylinder, cylinder-heads, a jacket separated from and surrounding said cylinder, exhaust-recesses in the cylinder-heads communicating with the space formed between the jacket and the cylinder, a piston, and steam-chest provided with a steam-inlet, exhaust-valves in said exhaust-recesses, rods connecting said exhaust-valves, whereby the said valves are adapted to alternately open and close, and means in the steam-chest for admitting steam directly therefrom, alternately to the ends of the cylinder.

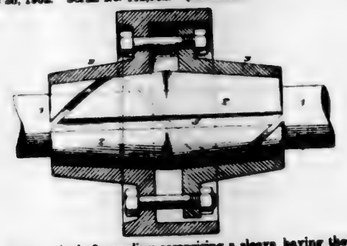
5. In a steam-engine, cylinder-head exhaust-valves located in each cylinder-head and adapted to alternately project into the cylinder, said valves each consisting of a head, a stem and a spring projecting forwardly from the face of the valve into the cylinder, said projecting springs being adapted to receive the impact of the piston-head and be compressed thereby, whereby the exhaust-valves will be gently moved to their seats, and rods connecting said exhaust-valves.

6. In a steam-engine, the combination with a cylinder, cylinder-heads, inclosed piston, exhaust-passages in the cylinder-heads, valve-seats in the said exhaust-passages, scallops or pockets adjacent to and surrounding said valve-seats, of exhaust-valves comprising a head, a stem, forwardly-projecting compressible cushions secured to the front face of the valve, and rods connecting the said valves, whereby they are adapted to alternately open and close the exhaust-passages in the cylinder-heads by the impact of a piston.

7. A cylinder having its heads provided with sockets in their inner faces adapted to receive exhaust-valves, scallops or pockets adjacent to and surrounding said sockets, said valves carrying forwardly-projecting springs adapted to receive and be compressed by the impact of a piston, whereby the faces of said valves will be caused to lie flush with the inner faces of the heads, when moved to their seats.

8. A steam-engine comprising a cylinder, cylinder-heads, exhaust-ports in said cylinder-heads, a piston, a steam-chest provided with a steam-inlet, exhaust-valves in the said exhaust-ports, rods connecting said exhaust-valves whereby they are adapted to alternately open and close, and means wholly within the steam-chest for admitting steam directly therefrom, alternately to the ends of the cylinder between the cylinder-heads and piston.

707,453. SHAFT-COUPLING. ROBERT W. SCOTT, Philadelphia, Pa., assignor of one-half to Louis H. D. Williams, Ashbourne, Pa. Filed June 23, 1902. Serial No. 112,912. (No model.)

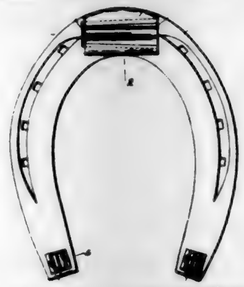


Claim.—1. A shaft-coupling comprising a sleeve having therein a spiral slot substantially encircling the same, in combination with means for compressing said sleeve so as to tighten the same upon the shafts to be coupled.

2. A shaft-coupling consisting of a sleeve having a spiral slot substantially encircling the same and having an exterior double-cone formation in combination with a pair of compressing-cones acting upon said sleeve, substantially as specified.

3. A shaft-coupling consisting of a sleeve having therein a spiral slot substantially encircling the same and having between the ends of said slot a substantially uninterrupted longitudinal portion with key-seat formed therein, in combination with means for compressing the sleeve, substantially as specified.

707,454. HORSESHOE. FRED SHEELEY, Fleischmanns, N. Y. Filed Dec. 27, 1901. Serial No. 87,414. (No model.)



Claim.—1. In a horseshoe, a block secured to the toe portion of the shoe, and having a slot, the opposite side walls of this slot being undercut, a toe-calk, a base on said toe-calk having its edges designed to engage with said undercut walls, and a lip on one end of the base adapted to be turned against the block.

2. In a horseshoe, a block on the toe portion of said horseshoe, and having a channel or groove, the opposite side walls of which are undercut and converged at one end, a wedge-shaped toe-calk, a base on said calk having beveled edges for engaging with said walls of the channel, and a lip on one end of the base adapted to be turned against the end of the block.

707,455. WIRE FENCING. MADISON D. SHIPMAN, DeKalb, Ill. Filed Apr. 28, 1897. Renewed Apr. 14, 1902. Serial No. 102,959 (No model.)

Claim.—In a wire fence, the combination of twisted wire cables and intersecting tie-wires, the latter having loops, the crowns of which are passed between the strands of the cable to closely embrace one of said strands.

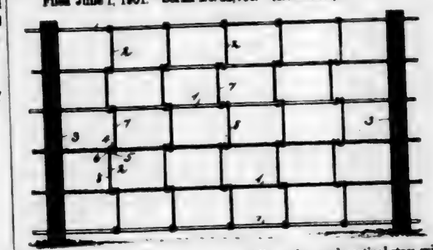
707,456. BUTTON AND PROCESS OF MAKING SAME. MADISON D. SHIPMAN, DeKalb, Ill. Filed May 1, 1900. Serial No. 15,103. (No model.)

Claim.—1. A plastic button having a fastener clenching recess in its back surface, said recess having a smooth round inner wall and a contracted opening thereto, said button being secured to the material by a fastener having a closed upper end passed through the material into the recess and clenched by the inner wall of the recess, the contracted opening engaging the fastener on a line with the upper surface of the material, substantially as described.

2. A plastic button having a smooth round recess in its back surface to form an upsetting-anvil for a fastener, and a contracted entrance to said recess, to hold the fastener in place, in combination with a fastener having a closed upper end forced into the recess and spread against the wall of the recess, substantially as described.

3. The process of molding plastic buttons which consists in forming a fastener-clenching recess or anvil in the back surface of the button-blank, said recess being of equal extent from its entrance-opening to the round clenching-surface, at the base of the recess, and subsequently compressing the plastic material around the opening of said recess prior to the attachment of the button to the material by a fastener to form a contracted entrance to said recess, substantially as described.

707,457. WIRE FENCE. MADISON D. SHIPMAN, DeKalb, Ill. Filed June 1, 1901. Serial No. 62,716. (No model.)



Claim.—A wire fence consisting of line-wires and vertical stay-wires secured thereto by loops in the stay-wires, said loops being doubled and clamped tightly around the line-wires and forming double arm-clamps extending around one-half of the circumference of the line-wires, and the vertical portions at opposite sides of the loop lying upon opposite sides of the line-wires and in parallel vertical planes.

707,458. AUTOGRAPHIC REGISTER. JAMES C. SHOUP, New York, N. Y., assignor to Henrietta Prewett Shoup, New York, N. Y. Filed July 30, 1901. Serial No. 69,096. (No model.)

Claim.—1. In an autographic register, a two-part writing-tablet and a plurality of reels bearing strips of paper, in combination with primary gripping-rolls for feeding strips of paper over the tablet out of the machine, and secondary gripping-rolls located below and actuated by the primary rolls for feeding a strip of paper over a portion of the tablet to a storage-roll.

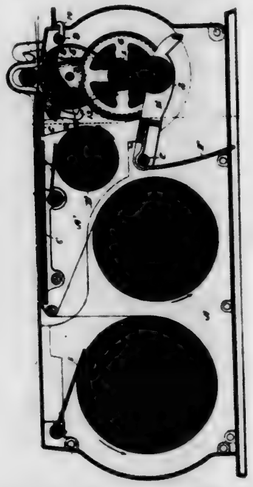
2. In an autographic register, a two-part writing-tablet and a plurality of leaves bearing strips of paper, in combination with primary gripping-rolls for feeding strips of paper over the tablet out of the machine secondary gripping-rolls below the primary rolls for feeding a strip of paper over a portion of the tablet to a storage-roll and reducing-gearing between the primary and the secondary rolls.

3. In an autographic apparatus, divided in two parts hinged together, a tablet, a pair of gripping-rolls supported in one part in combination with a second pair of gripping-rolls, having one roll supported in the part carrying the first pair of gripping-rolls, and one of the gripping-rolls forming the second pair supported in the other part of the casing.

4. In an autographic register, a stationary portion having mounted therein a spring-pressed frame carrying a storage-roll, and a series of dispensing-reels, in combination with a movable portion carrying a two-part writing-tablet and a supplemental dispensing-reel, mechanism for feeding the paper from the reels over the writing-tablet without the machine, and a guide-roll for feeding the paper from the supplemental reel over a portion of the tablet and winding it upon the storage-reel.

5. In an autographic register employing a check-strip and a record-strip, the combination of a tablet-plate adapted to have the check-strip

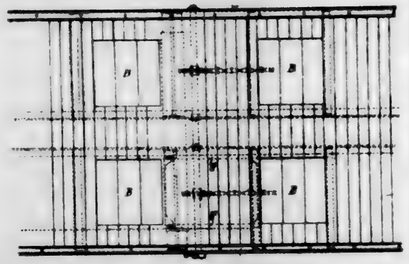
passed over the entire length of it and provided with an opening through which the record-strip may be passed and led over only a portion of the plate, and a transfer-sheet between the two strips, whereby only a part of the matter written upon the check-strip will be duplicated upon the record-strip.



6. In an autographic register employing a check-strip and a record-strip, the combination of a tablet-plate adapted to have the check-strip passed over the entire length of it and provided near one end with a transverse slot through which the record-strip may be passed from the under side of the plate and led over only a portion of the plate, and a transfer-sheet between the strips, whereby only a part of the matter written upon the check-strip will be duplicated upon the record-strip.

7. In an autographic register employing a check-strip and a record-strip, the combination of a tablet-plate adapted to have the check-strip passed over the entire length of it and provided with an opening through which the record-strip may be passed and led over only a portion of the plate, a transfer-sheet between the strips, and a storage-reel for winding up the record-strip, substantially as described.

707,459. OPERATING DEVICE FOR CAR-DOORS. JACKSON S. HOSTON, Altoona, Pa. Filed May 17, 1902. Serial No. 107,747. (No model.)



Claim.—1. The combination of a car having an opening or openings through the bottom thereof, sliding doors for said openings, a revoluble shaft supported by the car, and a series of links having its free ends connected respectively to said shaft and to the doors, the said series being constructed to operate positively and directly both to open and to close said doors, substantially as described.

2. The combination of a car having an opening or openings through the bottom thereof, sliding doors for said openings, a revoluble shaft carried by the car, an operating-wheel on the shaft and a link or links connected at one end to the said wheel and connected at the other end with the doors, with means whereby said wheel and links are caused to operatively move said doors irrespective of the direction of revolution of the shaft, substantially as described.

3. The combination of a car having an opening or openings through the bottom thereof, sliding doors for said openings, a revoluble shaft carried by the car, a toothed wheel on the shaft and a link or links positively connected at one end to the wheel and connected at the other end with the door or doors and constructed to be engaged by the teeth of the wheel, with means for causing said parts to operate directly upon the doors when the shaft is revolved in either direction, substantially as described.

4. The combination of a car having an opening or openings through the bottom thereof, sliding doors for said openings, a revoluble shaft carried by the car, a toothed wheel on said shaft, a series of links extending between said wheel and one of the doors, said links having on them means whereby they are retained in a substantially straight line when subjected to a compressive strain in operating said doors, substantially as described.

5. The combination of a car having openings therein, a door or doors for the same, a revoluble shaft supported by the car, a wheel thereon, links pivoted together and connecting said wheel with the door, certain of said links having sockets and others having portions constructed to engage said sockets when the links are subjected to a compressive strain, whereby they are maintained in a substantially straight line, substantially as described.

6. The combination of a car having openings therein, a door or doors for the same, a revoluble shaft supported by the car, a wheel thereon, links loosely pivoted together and connecting the wheel with the door, certain of said links having sockets and others having portions constructed to engage the same, the said connections between the links including means whereby they are maintained in a substantially straight line when subjected to a compressive strain while being free to turn on their pivots when under a tensile strain, substantially as described.

7. The combination of a car having openings, a door or doors for the same, a revoluble shaft supported by the car, a toothed wheel thereon, a series of loosely-connected links connecting the said wheel and the doors, arms on the links placed to be engaged by the teeth of the wheel and be thereby subjected to a compressive strain, with means for maintaining the links in a substantially straight line when so operated, substantially as described.

8. The combination of a car having openings, a door or doors for the same, a revoluble shaft supported by the car, a toothed wheel thereon, a series of loosely-connected links connecting the said wheel and the doors, arms on the links placed to be engaged by the teeth of the wheel and be thereby subjected to a compressive strain, certain of said links being free to move longitudinally relatively to each other and having means whereby they are held in a substantially straight line when so moved under a compressive strain, substantially as described.

9. The combination of a car, a plurality of openings therein, sliding doors for said openings, means operatively connecting certain of the doors, a revoluble shaft, a wheel thereon, links connecting the wheel with said connected system of doors, with means whereby said links are caused to transmit power to operate the system of doors both when subjected to a compressive strain and when under tensile strain applied through said wheel, substantially as described.

10. The combination of actuating mechanism, a system of links for transmitting power from said means both when subjected to compression and when under tension, the same consisting of individual links pivoted together so as to have a certain amount of lost motion, certain of the links being provided with sockets and others having portions constructed to engage with said sockets when the system is under compression, the sockets being constructed to retain the system of links in a substantially straight line as long as said system is under compression, with a device constructed to be operated by motion of a system of links, substantially as described.

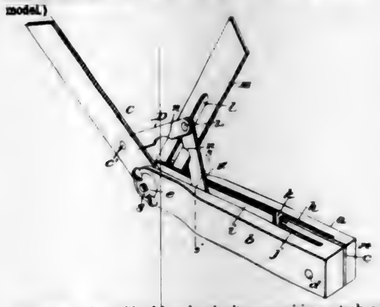
707,460. FINGER-BAR FOR HARVESTING-MACHINES. JOHN F. STEWARD, Chicago, Ill. Filed July 11, 1902. Serial No. 115,198. (No model.)

Claim.—1. A platform-bottom for harvesting-machines having a downward depression immediately below the conveyer driving-rollers, substantially as described.

2. A finger-bar for harvesting-machines having a downward depression immediately below the conveying-canvas rollers, substantially as described.

3. A platform for harvesting-machines, having a finger-bar with a downward depression and a bottom with a downward depression corresponding therewith, said depression being immediately below the endless conveyer-rollers, substantially as described.

707,461. COMBINED BEVEL AND MITER. CHARLES R. STEDMAN, Cleveland, Ohio. Filed Nov. 30, 1901. Serial No. 84,231. (No model.)



Claim.—1. A combined bevel and miter comprising a stock, a blade pivotally connected thereto, a second blade pivotally connected to the stock and having a longitudinal slot, and leaves pivotally connected together and to the first-named blade and stock, and having a lateral projection arranged to be pushed endwise into and withdrawn from the slot of the second-named blade.

2. A combined bevel and miter comprising a stock, a blade pivotally connected thereto, a second blade pivotally connected to the stock and having a longitudinal slot, resilient leaves pivotally connected to the first-named blade and the stock, respectively, and a pintle pivotally connecting the adjacent ends of the leaves and having an extended portion adapted, by reason of the resiliency of the leaves, to be sprung endwise into and out of the slot of the second-named blade.

3. A combined bevel and miter comprising a stock, a blade pivotally connected thereto, a second blade pivotally connected to the stock, and having a longitudinal slot, leaves pivotally connected together and to the first-named blade and stock, and having a lateral projection arranged to be pushed endwise into and withdrawn from the slot of the second-named blade, means for adjustably fixing the first-named blade and the leaves with respect to the stock, and means for adjustably fixing the second-named blade with respect to the stock.

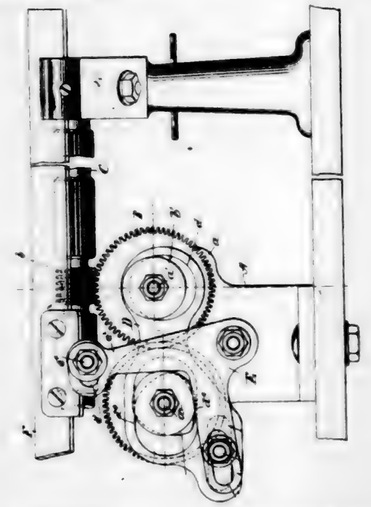
4. A combined bevel and miter comprising a stock having a division-plate and side sections, and also having the pockets *h i j* and the notch *k*, blades B, C, the former of which is slotted, a transverse bolt pivotally connecting said blades and the stock, and having screw-threaded ends and nuts thereon, and leaves pivotally connected together and to the stock and blade C, respectively, and having a lateral projection arranged to be pushed endwise into and withdrawn from the slot of blade B.

5. A combined bevel and miter comprising a stock having a division-plate and side sections, and also having the pockets *h i j* and the notch *k*, blades B, C, the former of which is slotted, a transverse bolt pivotally connecting said blades and the stock, and having the collar *f*, and also having screw-threaded ends, and nuts thereon, and leaves pivotally connected together and to the stock and blades C, respectively, and having the notches *n* in their inner edges, and also having a lateral projection arranged to be pushed endwise into and withdrawn from the slot of blade B.

6. A combined bevel and miter comprising a stock, blades pivotally connected to the stock upon a common axis, and leaves pivotally connected together and one of them to one of the blades and the other to the stock, and adjustably connected to the other blade; the said leaves being of a greater length than the distance between the points at which they are connected to the stock and blade and the point where the blades are connected to the stock, whereby an increased range of action is afforded.

707,462. SPINNING OR ROVING MACHINE. WILLIAM V. TERRELFALL, Biddeford, Me., assignor to Saco & Pettee Machine Shops, Newton, Mass., a Corporation of Massachusetts. Filed Apr. 19, 1902. Serial No. 103,759. (No model.)

Claim.—1. In a machine of the character specified, the combination of a driven gear, an eccentric on its face, a second gear meshing with and driven by the first, a cam, constructed as specified, upon its face, a lever provided at one end with a hole to fit the eccentric on the first-named gear and at its other end with a slot to receive the cam upon said second gear, adapted to have an endwise movement imparted to it by the eccentric and a continuous crosswise and quick reversing movement by contact of said cam with coöperating surfaces of said slot, the said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, the traverse slide or rail and a connection between said traverse slide or rail and said lever.



2. In a machine of the character specified, the combination of a driven gear, an eccentric on its face, a second gear meshing with and driven by the first but at a rate of rotation differing from that of the first, a cam, constructed as specified, upon its face, a lever provided at one end with a hole to fit the eccentric on the first-named gear and at its other end with a slot to receive the cam upon said second gear, adapted to have endwise movement imparted to it by the eccentric and a continuous crosswise and quick reversing movement by contact of said cam with coöperating surfaces of said slot, the said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, the traverse slide or rail and a connection between said traverse slide or rail and said lever.

3. In a machine of the character specified, the combination of a stand, a driven gear mounted thereon, an eccentric on its face, a second gear mounted upon the stand meshing with and driven by the first at a rate of rotation differing from that of the first, a cam, constructed as specified, upon its face, a lever provided at one end with a hole to fit the eccentric on the first-named gear and at its other end with a slot to receive the cam upon said second gear, adapted to have endwise movement imparted to it by the eccentric and a continuous crosswise and quick reversing movement by contact of said cam with coöperating surfaces of said slot, the said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, the traverse slide or rail and a connection between said traverse slide or rail and said lever.

4. In a machine of the character specified, the combination of a driven gear, an eccentric on its face, a second gear meshing with and driven by the first and at a rate of rotation varying from that of the first, a cam, constructed as specified, upon its face, a lever connected with said eccentric and with said cam, to be continuously moved and rapidly reversed by their conjoint action, a second lever, an adjustable connection between the two levers, a traverse slide or rail and an adjustable connection between the second lever and said slide or rail.

5. In a machine of the character specified, the combination of a driven gear, an eccentric on its face, a second driven gear adapted to be rotated at a rate varying from that of the first, a cam, constructed as specified, upon its face, a lever connected with said eccentric and with said cam to be positively and continuously moved and rapidly reversed by their conjoint action, the said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, a traverse slide or rail and a connection between said slide or rail and said lever.

6. In a machine of the character specified, the combination of an eccentric, a cam, constructed as specified, and adapted to be rotated at a speed varying from that of the eccentric, a lever connected with said eccentric and with said cam, to be positively moved and with a continuous and variable stroke and to be quickly reversed by their conjoint action, said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, a traverse slide or rail and said lever.

7. In a machine of the character specified in combination with the

drawing-rolls, a traversing thread slide or rail and means for imparting to it strokes varying in length but of uniform speed throughout and with a quick reversing movement at the end of each stroke, said means comprising an eccentric, a cam and a lever connecting said eccentric and said cam, and means operated thereby for imparting motion to said traversing thread-slide, said cam being constructed to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric.

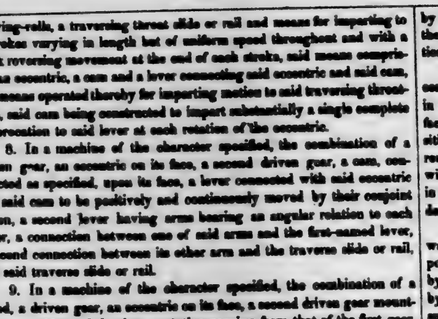
8. In a machine of the character specified, the combination of a driven gear, an eccentric on its face, a second driven gear, a cam, constructed as specified, upon its face, a lever connected with said eccentric and said cam to be positively and continuously moved by their conjoint action, a second lever having arms bearing an angular relation to each other, a connection between one of said arms and the first-named lever, a second connection between its other arm and the traverse slide or rail, and said traverse slide or rail.

9. In a machine of the character specified, the combination of a stand, a driven gear, an eccentric on its face, a second driven gear mounted upon said stand, having a rotation varying from that of the first gear, a cam, constructed as specified, upon its face, a lever connected with said eccentric and with said cam to be positively and continuously moved in strokes varying in length, and having a quick reversal by their conjoint action, a second lever pivoted to said stand, having arms angularly arranged with relation to each other, an adjustable connection between one of said arms and said lever, a connection between the other of said arms and the traverse slide or rail, and said traverse slide or rail.

10. In a machine of the character specified, the combination of an eccentric, a cam independent of the eccentric, constructed as specified and rotated at a speed varying from that of the eccentric, means for operating said eccentric and said cam, a lever connected with said eccentric and with said cam, to be positively and continuously moved in variable strokes at substantially the same speed throughout by their conjoint action, said cam being adapted to impart substantially a single complete reciprocation to said lever at each rotation of the eccentric, a traverse slide or rail, and an adjustable connection between said traverse slide or rail and said lever.

11. The combination in a machine of the character specified of a stand, two gears mounted thereon substantially side by side and so as to mesh with each other and having their faces exposed and one of which gears is driven by a worm, an eccentric-fulcrum on the face of one of said gears, a vibrator-cam upon the face of the other of said gears, a lever mounted upon said fulcrum and cam having a hole at one end to receive the fulcrum and an elongated slot at the other end to receive the cam, the said lever also having a slot in which an engaging pin or stud is adapted to play, a rock-lever mounted upon said stand having two arms, one of which has a longitudinal slot carrying a pin or stud which enters the pin-slot of said lever, and the other of which has a cross-slot which carries a pin connecting it with the traverse slide or rail, and the said traverse slide or rail.

707,463. ROLLER-BEARING. JOHN D. TWEED, Jr., New York N. Y. Filed Feb. 17, 1900. Renewed May 16, 1902. Serial No. 107,684. (No model.)



Claim.—1. A roller-bearing, comprising a block made in sections removably connected together and formed with an annular raceway, rollers mounted in said raceway and adapted to travel therein and on the peripheral surface of the journal, and a retaining device carried by the upper section of the block for holding the rollers in position in the upper section of the said block when the lower section is removed, substantially as shown and described.

2. A roller-bearing, comprising a block made in sections removably connected together and formed with an annular raceway, rollers mounted in said raceway and adapted to travel therein and on the peripheral surface of the journal, and automatically-movable retaining devices carried by the upper section of said block, and arranged to automatically retain the rollers in the upper section in position upon removing the lower section, substantially as shown and described.

3. A roller-bearing, comprising a block made in sections removably connected together and formed with an annular raceway, rollers mounted in said raceway and adapted to travel therein and on the peripheral surface of the journal, and a retaining device for holding the rollers in position on the upper section of the said block when the lower section is removed, the retaining device being normally held out of engagement with the rollers by the lower block-section as long as the latter is secured in place in connection with the upper section, substantially as shown and described.

4. A roller-bearing, comprising a block formed with an annular raceway, rollers mounted in said raceway, and a lubricant-reservoir on the top portion of the block and extended lengthwise of the rollers and connected by conducting-channels with the annular raceway to lubricate the rollers by a lubricant flowing by gravity from the reservoir, substantially as specified.

5. A roller-bearing comprising a block formed with an annular raceway, rollers mounted in said raceway, a lubricant-reservoir on the top of the upper portion of the block and extended lengthwise of the rollers, the said reservoir communicating with the raceway, and a casing or box containing said block and having filling-holes for filling the said reservoir with lubricant, substantially as specified.

6. A roller-bearing, comprising a block made in sections removably connected together and formed with an annular raceway, rollers mounted in said raceway, and adapted to travel therein and on the peripheral surface of the journal, a retaining device for holding the rollers in position in the upper section of the said block when the lower section is removed, said retaining device comprising a retaining-plate mounted to slide on the under side of the upper block-section at one side of the rollers, and a weighted lever fulcrumed on the upper section and engaging the said plate, to shift the latter inward under the lowermost roller in the upper section upon removing the lower section, substantially as shown and described.

7. A roller-bearing, comprising a block made in sections removably connected together and formed with an annular raceway, rollers mounted in said raceway and adapted to travel therein and on the peripheral surface of the journal, a retaining device for holding the rollers in position in the upper section of the block when the lower section is removed, said retaining device comprising a retaining-plate mounted to slide on the under side of the upper block-section at one side of the rollers, and a weighted lever fulcrumed on the upper section and engaging the said plate, to shift the latter inward under the lowermost roller in the upper section upon removing the lower section, the weight on the lever normally resting on the lower section, substantially as shown and described.

707,464. LOCKING DEVICE FOR VEHICLE STEERING MECHANISM. CORNELIUS S. VAN WAGONER, Cleveland, Ohio, assignor to M. L. Van Wagoner, Brooklyn, N. Y. Filed Sept. 6, 1901. Serial No. 74,533. (No model.)

Claim.—1. In a locking device for vehicle steering mechanism the combination of a friction-clutch comprising a non-rotatable member adapted to be secured to the frame or body of a vehicle, and a rotatable member surrounding said non-rotatable member and adapted to be secured to a vehicle steering mechanism, means for normally maintaining said members in frictional engagement, and means for releasing such engagement and imparting rotary motion to said rotatable member for moving said steering mechanism, substantially as described.

2. In a locking device for vehicle steering mechanism, the combination of a friction-clutch comprising a fixed member adapted to be secured to the frame or body of a vehicle, a rotatable member surrounding said fixed member and adapted to normally grasp the same, means for connecting said rotatable member to the vehicle steering mechanism, and means for releasing it from and rotating it around said fixed member, substantially as described.

3. In a locking device for vehicle steering mechanism, the combination of a clutch, means for connecting the fixed member thereof to the frame or body of a vehicle, a rotatable case inclosing said clutch, means for connecting said case to a vehicle steering mechanism, suitable connections between said clutch and case for normally holding the latter against rotation, and means for releasing said clutch and rotating said case, substantially as described.

4. In a locking device for vehicle steering mechanism, the combination of a fixed clutch member, means for rigidly securing said member to the frame or body of a vehicle, a rotatable clutch member surrounding said fixed member and adapted to normally grasp the same, means for connecting said rotatable member to a vehicle steering mechanism, a rotatable shaft, and suitable connections from said shaft to said rotatable clutch member whereby the latter will be released from and rotated around said fixed member by the rotation of said shaft, substantially as described.

5. In a locking device for vehicle steering mechanism, the combination of a cylindrical clutch member, means for rigidly securing said member to the frame or body of a vehicle, hinged clutch-sections surrounding said fixed member and adapted to normally grasp the same, means for connecting said clutch-sections to a vehicle steering mechanism, and means for separating said sections and rotating them around said fixed member, substantially as described.

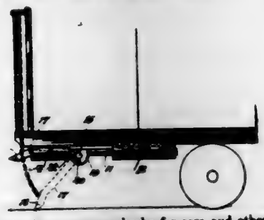
6. In a locking device for vehicle steering mechanism, the combination of a cylindrical clutch member, annular wedge-shaped projections thereon, means for rigidly securing said member to the frame or body of a vehicle, hinged clutch-sections surrounding said fixed member and adapted to frictionally engage the same, said sections being provided with grooves for receiving the annular projections on the fixed clutch member, means for connecting said sections to a vehicle steering mechanism, and means for separating said sections and rotating them around the fixed clutch member, substantially as described.

7. In a locking device for vehicle steering mechanism, the combination of a cylindrical clutch member, means for rigidly securing said member to the frame or body of a vehicle, hinged clutch-sections surrounding said fixed clutch member, means for connecting said sections to a vehicle steering mechanism, a shaft journaled in said fixed member, and connections from said shaft to said hinged sections whereby the latter will be moved from and rotated around said fixed member by the rotation of said shaft, substantially as described.

8. In a locking device for vehicle steering mechanism, the combination of a cylindrical clutch member, means for rigidly securing said member to the frame or body of a vehicle, clutch-sections surrounding said fixed member and adapted to normally grasp the same, a rotatable case inclosing said sections and connected thereto, means for connecting said case to a vehicle steering mechanism, and means for separating and rotating said sections, substantially as described.

9. In a locking device for vehicle steering mechanism, the combination of a cylindrical clutch member, means for rigidly securing said member to the frame or body of a vehicle, hinged clutch-sections surrounding said fixed member and adapted to normally grasp the same, a rocking lever between said sections for separating the same, a rotatable case inclosing said sections and coupled thereto, means for connecting said case to a vehicle steering mechanism, a shaft journaled in said fixed clutch member, and a projection therefrom for moving said rocking lever and thereafter rotating said case, substantially as described.

707,465. EMERGENCY-BRAKE. CARL VOGEL, Newburgh, N. Y. Filed Mar. 7, 1902. Serial No. 97,995. (No model.)



Claim.—1. An emergency-brake for cars and other vehicles, comprising a brake-bar having a body portion consisting of curved members and mounted to turn at its ends, the said body portion being provided with an arm at an angle to the body of the bar and in the same plane with said body, a beak extending downwardly and outwardly from the arm at an obtuse angle to the same, and means for limiting the turning movement of the brake-bar to hold it in operative position, the movement of the vehicle forcing the beak into the surface over which the vehicle is passing, as set forth.

2. In emergency-brakes, cylinders adapted for attachment to a car, pistons for the cylinders, bearings secured to the pistons, a brake-bar having its ends journaled in said bearings and provided with an arm at an angle to the body of the bar and in the same plane therewith, a beak extending at an obtuse angle from the arm in a downward and outward direction, and means for operating the piston-rods in one direction through the rotation of the brake-bar, as described.

3. In emergency-brakes, cylinders arranged in pairs, the cylinders of a pair being one behind the other, which cylinders are adapted for attachment to a car, springs located in the inner cylinders, pistons operating in the cylinders of a pair and against the springs in the inner cylinders, bearing-boxes secured to the pistons at points between the cylinders, said bearing-boxes having angular recesses in their side surfaces, facing in opposite directions and extending from the front and rear faces of the boxes to a connection with the bores thereof, a brake-bar the ends of which are journaled in the bores of the said boxes, the brake-bar being provided with lugs at its journaled ends at right angles to each other, a lug being adapted to operate in each recess of the bearing-boxes, an arm extending at an angle from the brake-bar, which arm is in the same plane with the body of the brake-bar, a beak extending downward and outward from the arm at an obtuse angle thereto, and means for raising the said brake-bar, which brake-bar is adapted to drop through gravity, as and for the purpose specified.

4. The combination with the body of a car, of a gravity emergency-brake, comprising a bar journaled at its ends in bearings carried by a support mounted to slide beneath the car, the said bar being provided with a beak at an obtuse angle to the body of the car and having a downward and outward inclination, means for raising the said brake, the brake being arranged to drop through gravity and the beak being adapted to strike and dig into the surface over which the car is passing, at an obtuse angle to the body of the car, means for limiting the turning movement of the brake-bar in its bearings, to hold the brake in operative position, and a cushion device for the sliding support for the bearings for the brake-bar, as set forth.

5. The combination with the body of a car, of a gravity emergency-brake comprising a bar pivoted at its ends in bearings beneath the car and provided with a beak at an obtuse angle to the body of the car and having a downward and outward inclination, which beak is adapted to strike the surface over which the car is passing, at an obtuse angle to the horizontal of the car, means for limiting the turning movement of the brake-bar in its bearings, and cushions operated by the movement of the brake-bar to check the car, as and for the purpose set forth.

6. In emergency-brakes, the combination with the body of a car or other vehicle, of cylinders secured to the under surface of the body of the vehicle one behind the other, a piston-rod provided with heads operating in the cylinders, a bearing on the piston-rod at a point between the cylinders, and a gravity-brake journaled in the bearing and adapted to engage the surface over which the vehicle is passing, as described.

7. In emergency-brakes, cylinders adapted for attachment to a car or other vehicle, pistons for the said cylinders, bearings secured to the piston-rods, and a brake-bar having its ends journaled in said bearings and provided with a member adapted to engage the surface over which the vehicle may be traveling, and means for operating the piston-rods in one direction from the brake-bar as set forth.

8. An emergency-brake for cars and other vehicles, comprising a brake-bar having a body portion consisting of curved members, the body portion being mounted to turn at its ends and provided at said ends with means for limiting their turning movement, the brake-bar having an outwardly-extending arm at an angle to the body of the bar and in the same plane with said body, and a beak extending downwardly and outwardly from the outer end of said arm at an obtuse angle to the same, for the purpose set forth.

9. The combination with the body of a car or other vehicle, of a gravity emergency-brake journaled beneath the car and provided with a beak adapted to engage the surface over which the car is passing, and a clutch connection between the brake and the bearing in which it is journaled, to limit the turning movement of the brake and hold it in operative position, as set forth.

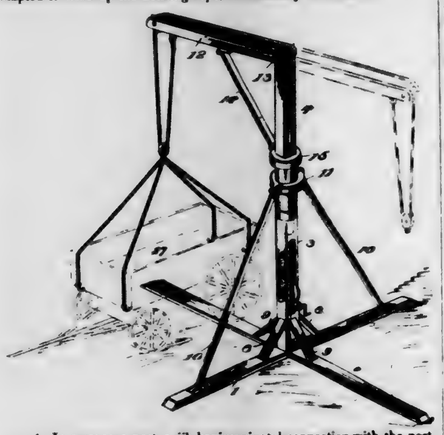
707,466. WAGON-BODY LIFTER. GEORGE H. WARE, Greeley Hehr. Filed Nov. 21, 1901. Serial No. 83,161. (No model.)

Claim.—1. In a wagon-body lifter, a crane comprising a jib, hoisting-tackle, a sectional post, and braces, the lower section of the post being fixed and the upper section being journaled thereto to turn about a vertical axis, and braces between the upper turnable section of the post and the support upon which the crane is placed, substantially as set forth.

2. In a wagon-body lifter, a crane comprising a jib, hoisting-tackle, a sectional post having its lower portion fixed and its upper part mounted to turn upon the lower section, braces between the lower section of the post and the post-support, a ring fitted to the upper section of the post, and braces between the said ring and the said post-support, substantially as set forth.

3. In combination, a sectional post, the lower section being fixed and the upper section mounted to turn upon the lower section about a verti-

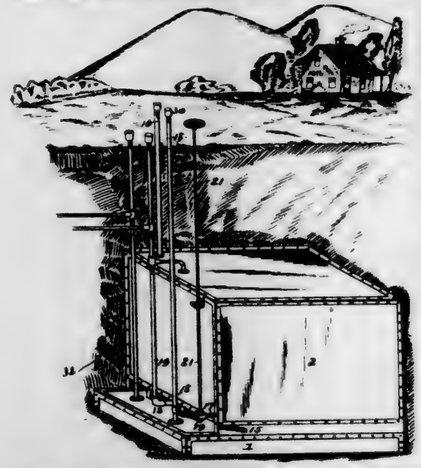
cal line, hoisting-rope passing through the joint between the sections of the post, and a windlass journaled to the fixed section of the post and adapted to wind up the hoisting-rope, substantially as set forth.



4. In a crane, a post, a jib having pivotal connection with the post, and braces having pivotal connection at its upper end with the jib, and an automatic clamp movable upon the post and having the lower end of the aforesaid braces pivoted thereto, substantially as set forth.

5. The herein-described wagon-body lifter comprising a base, a sectional post secured at its lower end to the base and having its upper portion mounted to turn upon the lower fixed portion, a jib pivoted to the turnable section of the post, and braces between the jib and the outer portion of the post and adjustable for varying the elevation of the outer end of the jib, a ring applied to the upper portion of the post, braces between the said ring and base, a windlass applied to the fixed section of the post, and a hoisting-rope passing through the joint between the sections of the post and adapted to have its lower end wind upon the windlass, substantially as specified.

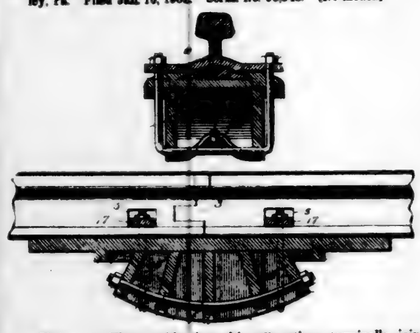
707,467. CARBURETER. EDWARD WALTHER, Washington Iowa. Filed Apr. 24, 1902. Serial No. 104,450. (No model.)



Claim.—1. In a carbureter, the combination with a vapor-generator located below the surface of the ground, of a perforated pipe screwed into a threaded aperture in said generator and extending up to the surface of the ground, an oil-shut-off valve mounted in said pipe and carrying a float located in said generator, a pipe surrounding said first-mentioned pipe and extending to the surface of the ground and supplied with a detachable cap, and gasolene connections for said last-mentioned pipe, substantially as described.

2. In a carbureter, the combination with a vapor-generator and a gasolene-supply tank both located below the surface of the ground, of a pipe connected to said generator and extending above the ground, said pipe having a detachable cap thereon, a pipe connecting said gasolene-supply tank and said pipe, a perforated pipe inclosed in said first-mentioned pipe and containing a valve arranged to be operated by the gasolene in said generator to regulate the flow of gasolene from said supply-tank to said generator, said last-mentioned pipe being mounted to be removed to obtain access to said valve, substantially as described.

707,468. RAILWAY-JOINT. THORSTON L. WATTS, Muncy Valley, Pa. Filed Jan. 18, 1902. Serial No. 90,348. (No model.)



Claim.—1. The combination with rail-sections terminally joined and having slots extending transversely therethrough, of a truss attachment disposed under the joint, and clip-bars projecting through the said slots and secured to the truss attachment.

2. The combination with rail-sections terminally joined and having slots extending therethrough, of a truss attachment disposed under the joint, clip-bars extending through the slots, and tie-clamps surrounding the truss attachment and terminally secured in the opposite extremities of the clip-bars.

3. The combination with rail-sections terminally joined and having slots extending transversely therethrough, of a truss attachment comprising a brace member, means partially extending through said slots for securing the brace member to the rail-sections, and a bonding-rod extending through said brace member.

4. The combination of rail-sections terminally joined and having transversely-extending slots therethrough, a chair in which the joint-terminals of the rail-sections are seated, a brace member disposed against the under side of the chair, clip-bars extending through the slots of the rail-sections, tie-clamps surrounding the brace member and terminally secured in the opposite extremities of the clip-bars, and a bonding-rod extending longitudinally through the lower portion of the brace member.

5. The combination with a railroad-rail joint, of a brace member disposed thereunder and secured thereto, said brace member having depending partitions with connecting side webs, and a bonding-rod extending centrally through the partitions, the said brace member having its greatest depth directly under the joint.

6. The combination with a railroad-rail joint, of a brace member disposed thereunder, means for securing the said brace member to the rail-sections and surrounding the brace member adjacent to the ends of the latter, and a bonding-rod extending longitudinally through the center of the lower portion of the brace member.

7. The combination with a railroad-rail joint, of a chair applied to the rail-sections under the joint and having opposite transversely-extending ribs at the bottom, a brace member having a top plate disposed against the bottom of the chair and terminally engaging the said ribs, means for connecting the brace member to the rail-sections and the chair, and means for longitudinally bonding said brace member.

707,469. GAME. WILLIAM M. WATTS, Detroit, Mich. Filed Oct. 23, 1901. Serial No. 80,242. (No model.)

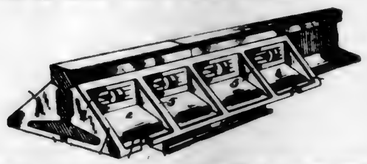
Claim.—The herein-described game comprising a map having represented thereon given cities, railway routes of different railway systems connecting the different cities, and distances between adjacent cities on any railway-line indicated on that line, a playing-piece for each player for advancement along the railway routes from city to city at a single jump, and a pack of cards each bearing the name of only one city represented on the map and corresponding in number to the cities represented on the map and used to indicate the starting-point and continuous course of travel of the playing-pieces over the map in traveling from one city to another according to the city represented on succeeding cards used by the player

---

707,470. SOLDER FOR SOLDERING ALUMINIUM. JOSEPH C. WEBSTER, Philadelphia, Pa. Filed Nov. 18, 1901. Serial No. 82,566. (No specimens.)

Claim.—The herein-described solder for soldering aluminium, which consists, respectively, of from five to six parts of tin, four to five parts of lead, six to four parts of aluminium, and one part of zinc, as described.

707,471. RAIL-JOINT. OLIVER R. WEDDELL, McKeesport, Pa. Filed Apr. 21, 1902. Serial No. 103,967. (No model.)



Claim.—1. In combination with the rails having apertures, fish-plates having underlying portions provided with oblong apertures and provided with cam-surfaces on their outer faces, means extending through the apertures in said underlying portions and engaging said cam-faces, and means extending through apertures in the webs of the fish-plates and through the apertures in the rails and wedging against the outer faces of the fish-plate webs, substantially as described.

2. In combination with rails having apertures in the web thereof, fish-plates provided with ribs and having oblong apertures, underlying portions carried by said fish-plates and having oblong apertures therethrough, the outer faces of the fish-plates and the underlying portions having cam-surfaces, and means extending through the fish-plates and apertures in the rails for wedging action against the cam-faces, substantially as described.

3. In a rail-joint, a fish-plate provided in its web portion with a series of oblong apertures and having cam-faces above and below said apertures, and an underlying portion carried by said fish-plate provided with oblong apertures and having cam-faces above and below said apertures substantially as described.

4. In a rail-joint, a fish-plate having a series of strengthening-ribs and provided with oblong apertures, cam-faces formed on the outer face of the web of said fish-plate, and an underlying portion carried by the fish-plate with oblong apertures therethrough and cam-faces on the outer face of said underlying portion, as and for the purpose specified.

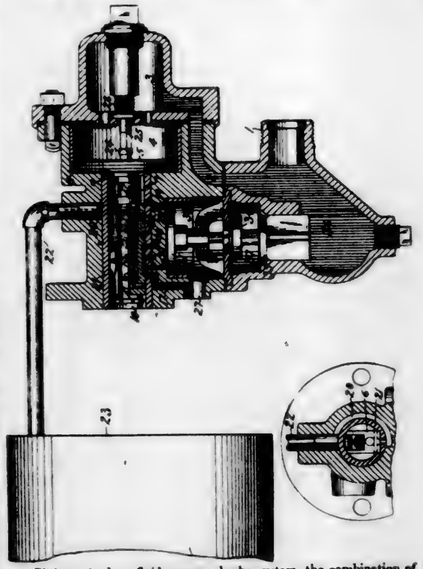
5. In a rail-joint, the combination with the rails having apertures, of fish-plates having apertures to register with the apertures in the rails, double-headed bolts passing through said apertures and wedging against the outer face of both fish-plates, underlying portions carried by the fish-plates and provided with apertures, and double-headed bolts passing through said last-named apertures and wedging against the outer face of the underlying portions, substantially as described.

6. The combination with the rails, of a pair of fish-plates having oblong openings which are enlarged near one end, each fish-plate having inclined recesses in the outer face to form countersunk inclined walls above and below the oblong openings, a series of strengthening-ribs on each of said plates, bolts having a substantially T-shaped head on each end and having shanks square in cross-section, the said rails having openings of a diameter substantially equal to the greatest diameter of the bolt-heads, the shanks of said bolts engaging the walls of the oblong openings in the fish-plates and free from engagement with the walls of the openings in the rails when the bolts are in the locked position, and the inner faces of the bolt-heads adapted to wedge against the countersunk inclined walls of the fish-plates, substantially as described.

707,472. TOOL-HOLDER. SAMUEL WELTER and JOHN ARMSTRONG, Chicago, Ill., assignors to Armstrong Bros. Tool Co., a Corporation of Illinois. Filed Mar. 27, 1901. Serial No. 53,156. (No model.)

Claim.—In a tool-holder for planing-machines, in combination, a shank, a head carried by the shank and having a curved slot, a bolt passing through the slot for securing the head to the shank, an adjustable stop entering the slot and adapted to engage the bolt, and a plurality of cutting-tools secured in and arranged in a line parallel to the head, the head being adapted to be adjusted so that the cutting edges of the tools will be in a line at an angle to the direction of travel.

707,478. FLUID-PRESSURE BRAKE. HENRY H. WESTINGHOUSE, Edgewood Park, Pa., assignor to the Westinghouse Air Brake Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Dec. 8, 1900. Serial No. 39,182. (No model.)



Claim.—1. In a fluid-pressure brake system, the combination of a train-pipe, a brake-cylinder, an auxiliary reservoir, a supplemental reservoir, a valve-chamber in communication with the auxiliary reservoir, a valve, a movable abutment for operating the valve according to variations of pressure in the train-pipe, and a port leading from the supplemental reservoir to the valve-chamber and adapted to be opened when

the valve is moved either to "release" position or to emergency position, and closed when the valve is at an intermediate position.

2. In a fluid-pressure brake system, the combination with a train-pipe, a brake-cylinder, an auxiliary reservoir and a supplemental reservoir, of an automatic valve mechanism operated by variations of the pressure in the train-pipe, said valve adapted to open communication from the supplemental reservoir to the auxiliary reservoir when in "release" position and also when in "emergency" position, and to close communication from the supplemental reservoir when in an intermediate position.

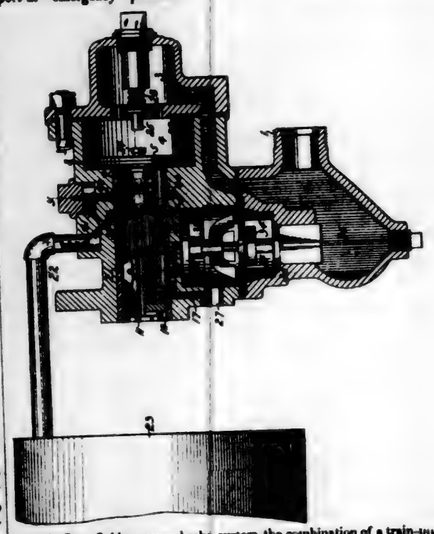
3. In a fluid-pressure brake system, the combination of a train-pipe, a brake-cylinder, an auxiliary reservoir, a supplemental reservoir, a valve-chamber communicating with the auxiliary reservoir, a valve, a movable abutment operated by variations in the train-pipe pressure for moving said valve to open communication from the auxiliary reservoir to the brake-cylinder and to close communication from the supplemental reservoir, when the valve is in an intermediate position, and to open communication from the supplemental reservoir to the valve-chamber when the valve is moved either to "release" position or to "emergency" position.

4. In a fluid-pressure brake system, the combination with a train-pipe, a brake-cylinder, an auxiliary reservoir and a supplemental reservoir, of an automatic valve mechanism operated by variations of pressure in the train-pipe and adapted, when in one position, to open communication from the train-pipe to the auxiliary reservoir and to the supplemental reservoir, and when in another position to open communication from the auxiliary reservoir to the brake-cylinder and to close communication to or from the supplemental reservoir, and when in a third position to open communication from the auxiliary reservoir to the brake-cylinder and from the supplemental reservoir to the auxiliary reservoir.

5. In a fluid-pressure brake system, the combination with a train-pipe, auxiliary reservoir, brake-cylinder and supplemental reservoir, of a valve device having a movable abutment operated by variations in train-pipe pressure, a main valve actuated thereby and adapted when in release position to open communication between the supplemental and auxiliary reservoirs, and when in service position to close communication from the supplemental reservoir and to open communication from the auxiliary reservoir to the brake-cylinder, and a graduating-valve having a movement relative to the main valve for controlling the fluid-supply to the brake-cylinder in service applications.

6. In a fluid-pressure brake system, the combination with a train-pipe, auxiliary reservoir, brake-cylinder, supplemental reservoir, of a valve-chamber in communication with the auxiliary reservoir, ports leading from the valve-chamber to the supplemental reservoir and to the brake-cylinder, a movable abutment operated according to variations in train-pipe pressure, a main valve actuated thereby to open said port leading to the supplemental reservoir when in release position, and to close said port and open the port leading from the auxiliary reservoir to the brake-cylinder when in service position, and a graduating-valve actuated by said abutment and having a movement relative to the main valve for controlling the supply-passage to the brake-cylinder.

7. In a fluid-pressure brake system, the combination with a train-pipe, auxiliary reservoir, brake-cylinder, and supplemental reservoir, of a triple-valve device having a valve-chamber in communication with the auxiliary reservoir, a port leading from the valve-chamber to the supplemental reservoir, a valve adapted to open said port at both release and emergency positions and to close said port at service position, and an emergency-valve controlling a passage from the train-pipe to the brake-cylinder in the train-pipe, a passage having a non-return valve for feeding the supplemental reservoir, and a port leading from the valve-chamber to the supplemental reservoir, said abutment-operated valve being adapted to close said port at "release" and "service-stop" positions and to open said port at "emergency" position.



4. In a fluid-pressure brake system, the combination of a train-pipe, a brake-cylinder, an auxiliary reservoir, a supplemental reservoir, a valve-chamber in communication with the auxiliary reservoir, a valve, a movable abutment or piston for operating said valve according to variations of pressure in the train-pipe, a port leading from the valve-chamber to the supplemental reservoir and provided with a non-return valve, and another separate port leading from the valve-chamber to the supplemental reservoir and adapted to be closed by said abutment-operated valve when in "release" and "service-stop" positions and opened when the valve is moved to "emergency" position.

5. In a fluid-pressure brake system, the combination with an automatic triple-valve device having a valve-chamber and a valve therein, of a supplemental reservoir and two ports leading from the interior of the valve-chamber to the supplemental reservoir, said valve being adapted to close both said ports when in "service-stop" position.

6. In a fluid-pressure brake system, the combination with an automatic triple-valve device having a valve-chamber and a valve therein, of a supplemental reservoir and two ports leading from the interior of the valve-chamber to the supplemental reservoir, said valve being adapted, when in "release" position, to open one of said ports and close the other, and when in "service-stop" position, to close both of said ports.

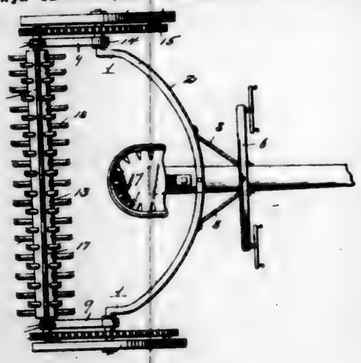
707,474. FLUID-PRESSURE BRAKE. HENRY H. WESTINGHOUSE, Edgewood Park, Pa., assignor to the Westinghouse Air Brake Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Dec. 13, 1900. Serial No. 39,675. (No model.)

Claim.—1. In a fluid-pressure brake system, the combination of a train-pipe, a brake-cylinder, an auxiliary reservoir, a supplemental reservoir, a feed-passage for said supplemental reservoir with means for preventing backflow through said passage, a valve-chamber, a valve with a movable abutment for operating the same according to variations of pressure in the train-pipe, and a port leading from the valve-chamber to the supplemental reservoir, said valve being adapted to close said port when in "service-stop" position and to open said port when in "emergency" position.

2. In a fluid-pressure brake system, the combination with an automatic triple-valve device having a valve-chamber in constant open communication with the auxiliary reservoir, of a supplemental reservoir and two passages leading from the valve-chamber to the supplemental reservoir, one of said passages having a non-return valve.

3. In a fluid-pressure brake system, the combination of a train-pipe, a brake-cylinder, an auxiliary reservoir, a supplemental reservoir, a valve-chamber in communication with the auxiliary reservoir, a valve, a movable abutment for operating the valve according to variations of pressure

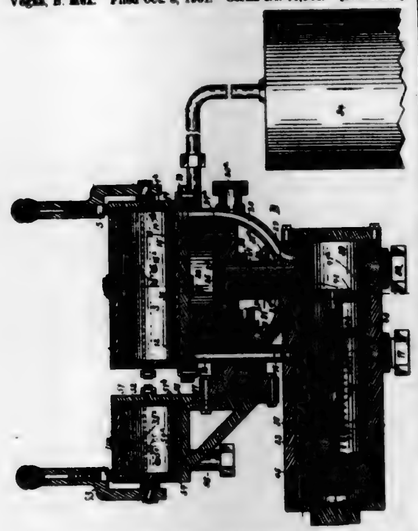
707,475. WEED-PULLER. JOSEPH A. WHELAN, Rock Springs, Wyo. Filed Oct. 23, 1901. Serial No. 79,731. (No model.)



Claim.—1. The combination with a frame having its ends outturned to form axles, of wheels journaled thereon, gear-wheels secured to said wheels, depending arms loosely mounted on said axles between the wheels and the frame and provided with bearings at their lower ends, a shaft journaled in said bearings, a toothed roller carried by said shaft, pinions mounted on said shaft to mesh with said gear-wheels, upwardly-extending arms on the lower ends of the said depending arms and having openings in their upper ends, and a rod mounted in the openings of the said arms for clearing the roller-teeth.

2. The combination with a frame formed with axles, of wheels journaled thereon, depending arms loosely mounted on said axles and provided with bearings at their lower ends, a shaft journaled in said bearings, a toothed roller carried by said shaft, an upwardly-extending arm formed integral with the lower ends of each of the said depending arms, and having openings in their upper ends, and a rod mounted in the openings of the said arms for clearing the roller-teeth.

707,476. EQUALIZING-VALVE. PAUL WHITING, East Las Vegas, N. Mex. Filed Oct. 3, 1901. Serial No. 77,970. (No model.)



Claim.—1. In a valve of the class described, the combination of a cylinder divided into front and rear compartments by a transverse partition, an adjustable head fitted into the rear end of said cylinder and provided with a stem, a piston located in said front compartment and having a hollow stem mounted in said partition and fitting over said stem, and a spring mounted on said hollow stem and bearing on said adjustable head, substantially as described.

2. In a valve of the class described, the combination of a cylinder divided into front and rear compartments by a transverse partition, an adjustable head fitted into the rear end of said cylinder and having a grooved stem, a piston located in said forward compartment and having a hollow stem slidingly mounted in said partition, and fitting over said stem, and a spring mounted on said hollow stem, substantially as described.

3. In a valve of the class described, the combination of a casing divided into front and rear compartments by a transverse partition, each of said compartments having an air-passage connected thereto, a piston mounted in said front compartment and having a hollow stem which is slidingly mounted in said partition, a valve-seat located in said rear compartment in position to close said hollow stem when seated thereon, a spring mounted on said hollow stem and arranged to hold it normally unseated, and a cylinder-valve comprising an outer and inner cylinder having ports located to be brought into register by turning said inner cylinder, said cylinder-valve being connected to regulate the flow of air through said air-passage, substantially as described.

4. In a valve of the class described, the combination of a lower cylinder divided into front and rear compartments by a transverse partition, a valve-seat mounted in said rear compartment, a piston mounted in said front compartment and provided with a hollow stem slidingly mounted in said partition and constructed to fit said seat, a spring surrounding said stem and arranged to normally hold it unseated, an exhaust-passage connected to said front compartment, an upper cylinder a piston mounted in said upper cylinder and provided with a stem constructed to regulate the exhaust of air through said passage, a passage connecting said upper and lower cylinder, air-passages connected to said upper cylinder and to the front and rear compartment of said lower cylinder, and means for regulating the flow of air through said passages, substantially as described.

5. In a valve of the class described, the combination of a lower cylinder divided into front and rear compartments by a transverse partition, a valve-seat mounted in said rear compartment, a piston mounted in said front compartment and provided with a hollow stem slidingly mounted in said partition and constructed to fit said seat, a spring constructed to normally hold said stem unseated, an air-passage connected to said rear compartment, means for regulating the flow of air through said passage, a pipe and an exhaust-passage connected to said front compartment, an upper cylinder, a piston mounted in said upper cylinder and provided with a stem constructed to serve as a valve to regulate the flow of air through said exhaust-passage, and an air-passage connecting said upper cylinder and said forward compartment, substantially as described.

6. In a valve of the class described, the combination of a lower cylinder comprising front and rear compartments, a valve-seat mounted in said rear compartment, a piston mounted in said front compartment and provided with a hollow stem extending into said rear compartment and constructed to fit said seat, a spring mounted to normally hold said stem unseated, an exhaust-passage and a pipe connected to said front compartment, an upper cylinder, a piston mounted in said upper cylinder and provided with a stem constructed to serve as a valve to regulate the flow of air through said exhaust, a reservoir connected to said upper cylinder to increase the capacity thereof, air-passages connected to said rear compartment and said upper cylinder, means for regulating the flow of air through said passages, and an air-passage connecting said upper cylinder and said front compartment, substantially as described.

7. In a valve of the class described, the combination with a cylinder, of a piston mounted in said cylinder and having a hollow stem forming a valve, a valve-seat located to coöperate with said hollow stem to regulate the flow of air from one side of said piston to the other, a spring mounted to regulate the amount of pressure necessary to move said piston to operate said valve, a passage connecting said cylinder to the open air, a second cylinder, connected to said first-mentioned cylinder by a passage, a piston mounted in said second cylinder and provided with a stem constructed to serve as a valve to open and close said passage to the open air, substantially as described.

8. In an air-brake system, the combination with a cylinder, of a piston mounted in said cylinder and having a hollow stem, a valve-seat mounted to close said stem when seated thereon, a spring mounted to oppose the seating of said hollow stem on said valve-seat, a main reservoir connected to said cylinder in the rear of said piston, a train-line connected to said cylinder at a point in front of said piston, a second cylinder, a piston mounted in said cylinder and bearing a stem mounted to serve as a valve to open and close an exhaust-passage communicating with the forward end of said first-mentioned cylinder, said second cylinder being connected to said first-mentioned cylinder at a point in front of the said piston therein, and means for regulating the flow of air into and out of said second cylinder, substantially as described.

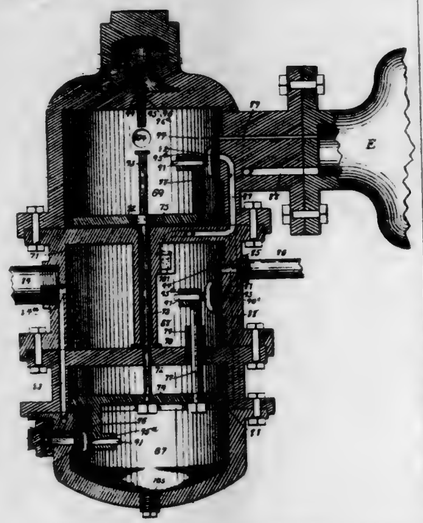
707,477. QUADRUPLE VALVE. PAUL WHITING, East Las Vegas, N. Mex. Filed Oct. 9, 1901. Serial No. 78,168. (No model.)

Claim.—1. In a valve of the class described, the combination, of a casing divided transversely into upper, middle and lower compartments, pistons located in said upper and lower compartments, a piston-rod connecting said pistons, an air-passage connected to each of said compartments, and a valve located in each of said compartments and connected to be simultaneously operated by said pistons to regulate the flow of air through said passages, substantially as described.

2. The combination with an auxiliary reservoir, of a valve-casing divided by transverse partitions into upper, middle, and lower compartments, a piston mounted in each of said upper and lower compartments, a piston-rod slidingly mounted in said partitions and connecting said pistons, an air-passage connecting said upper compartment and said reservoir, a valve mounted in said upper compartment and connected to operate in unison with said piston-rod, said valves being located to regulate the flow through said passage, a pipe connected to said upper compartment, a passage connecting said reservoir and said lower compartment, a passage connected to said lower compartment, and a valve mounted in said lower compartment, said valve being connected to operate in unison with said piston-rod, to regulate the flow of air through said last-mentioned passage, substantially as described.

3. In a valve of the class described, the combination of a casing divided transversely into upper, middle and lower compartments, pistons

located in said upper and lower compartments, a piston-rod mounted to slide and connecting said pistons, a pipe connected to said middle compartment and communicating with a passage communicating with said lower compartment, said passage having a triangular port, a slide-valve mounted to operate in unison with said piston-rod to open and close said triangular port, a passage connecting said upper and lower compartments, and a valve mounted in said upper compartment and designed to close said passage, substantially as described.



4. In a valve of the class described, the combination of a casing divided transversely into upper, middle and lower compartments, a piston-rod located in each of said upper and lower compartments, a piston-rod mounted to slide and connecting said pistons, an auxiliary reservoir, a passage connecting said auxiliary reservoir and said upper compartment, a passage connecting said upper and middle compartments, a slide-valve mounted in said upper compartment and arranged to operate in unison with said piston-rod to open and close said passages, a pipe adapted to be connected to a brake-cylinder, and communicating with said middle compartment, and a spring-actuated stem mounted in line with said piston-rod at the upper end thereof, said stem being constructed to normally serve as a bumper to limit the movement of said rod, but to be displaced by the contact of the piston-rod when an abnormal reduction of pressure is made in the said upper compartment, substantially as described.

5. In a device of the class described, the combination with a valve-seat, having a port and a longitudinal groove therein, a slide mounted in said groove and having transverse dovetailed slots in the back thereof, a transversely-apertured arm, a stem slidingly mounted in said arm and provided with dovetailed feet mounted in said dovetailed grooves, and a spring mounted on said stem and designed to hold said slide in its seat, substantially as described.

6. The combination with an auxiliary reservoir, of a valve-casing having an upper, a middle and a lower compartment, said upper compartment being connected by a first passage to said reservoir and by a second passage to said middle compartment, said middle compartment being constructed to communicate with the open air and to be connected to the main train-line, said lower compartment being connected by a passage to said reservoir and by a second passage to said middle compartment, pistons mounted in said upper and lower compartments, and connected to operate in unison, and valves mounted in said compartments and connected to be operated in unison with said piston to regulate the flow of air through said passages, substantially as described.

7. In a valve of the class described, the combination of a casing having an upper and a lower compartment, said upper compartment being constructed to be connected to a main train-line and to an auxiliary reservoir, said lower compartment being constructed to be connected to said auxiliary reservoir and to a brake-cylinder, pistons of equal area mounted in said upper and lower compartments, said pistons being connected to move in unison, and a valve mounted in each of said compartments, said valves being located to regulate the flow of air to said auxiliary reservoir and to said brake-cylinder, and connected to be actuated in unison with said pistons, substantially as described.

707,478. VALVE MECHANISM FOR STEAM-CARRIAGE BURNERS. ROLLIN H. WHITE, Cleveland, Ohio, assignor to the White Sewing Machine Company, Cleveland, Ohio, a Corporation of Ohio. Filed Apr. 19, 1901. Serial No. 56,542. (No model.)

Claim.—1. A valve-casing having an inlet-opening, a discharge-nozzle, and a valve-seat between them, and a valve having a screw-threaded connection with said casing, combined with a bracket having two integral bearing-sleeves, two shafts respectively mounted in said sleeves, intermeshing bevel-gears secured to said two shafts, and operative connection between one of said shafts and said valves, substantially as specified.

2. A valve-casing having an inlet-opening, a discharge-nozzle, and a valve-seat between them, combined with a valve having a screw-threaded connection with said casing, a rotatable shaft, and a universal-joint connection between said shaft and valve, and mechanism carrying said shaft and liable to be out of alinement with said valve, substantially as specified.

3. A valve-casing having an inlet-opening, a discharge-nozzle and a valve-seat between them, combined with a valve having a screw-threaded connection with said casing, a rotatable shaft, a universal-joint connection between said shaft and valve, the intermediate link being connected with said shaft or valve by pivot-pins, fast to one of the parts so connected, and passing through longitudinal slots in the other part, and mechanism carrying said shaft and liable to be out of alinement with said valve, substantially as specified.

4. In combination, a valve-casing having the following integral parts, viz. a vertical tube and an integral horizontal tube which extends across the end of said vertical tube, and a housing, said vertical tube having an inlet-opening and a valve-seat between said opening and the horizontal tube, the horizontal tube having at one end a discharge-nozzle and a valve-seat between said nozzle and the vertical tube, a valve in the vertical tube, a bell-crank lever pivoted in said housing and engaging with said valve, a rod for operating said bell-crank lever, a valve screwed into the horizontal tube, and a shaft operatively connected with said valve, substantially as specified.

5. A valve-casing comprising the following parts, viz. a vertical tube having an inlet-opening, a discharge-opening at its lower end, and a transverse valve-seat between said openings, a horizontal tube on the lower end of said vertical tube and communicating therewith through said discharge-opening, said horizontal tube having a discharge-nozzle and a valve-seat, and a laterally-projecting housing on said vertical tube and communicating therewith, combined with a valve screwed into the horizontal tube, operating mechanism therefor, a vertically-movable valve in the vertical tube, a collar adjustably secured upon the stem of this valve, a bell-crank lever pivoted in said housing with its horizontal arm beneath said collar, a plate secured to the end of said housing, a rod passing through said plate and engaging with the vertical arm of said bell-crank lever, said rod being part of a thermostat which is secured to said plate, and a steam-pipe embracing this thermostat, substantially as specified.

6. A valve-casing comprising the following parts, viz. a vertical tube having a screw-threaded opening through its upper end, a discharge-opening at its lower end, an inlet-opening between said ends, and a transverse valve-seat between said inlet and discharge openings, a plug screwed into the upper end of said vertical tube, a horizontal tube on the lower end of said tube and communicating therewith through said discharge-opening, said horizontal tube having a discharge-nozzle and a valve-seat, and a laterally-projecting housing on said vertical tube and communicating therewith, combined with a valve screwed into the horizontal tube, operating mechanism therefor, a vertically-movable valve in the vertical tube, a collar adjustably secured upon the stem of this valve, a bell-crank lever pivoted in said housing with its horizontal arm beneath said collar, a plate secured to the end of said housing and having a hole through it and a concentric circular rabbet in its inner face, a thermostat comprising an outer tube which passes through said hole and has on its inner end an external flange which lies in said rabbet, and a rod in said tube, which rod engages with the vertical arm of the said bell-crank lever, a screw-plug embracing said rod and screwing into said rabbet against the end of said thermostat-tube, and a steam-pipe embracing said thermostat, substantially as specified.

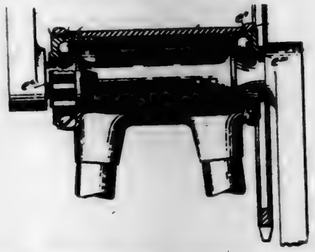
707,479. RIBBON AND STOCK SUPPORTER. JOSEPH H. WHITTINGTON, Buffalo, N. Y., assignor to The New York Supply Company, Buffalo, N. Y., a Firm. Filed Dec. 10, 1901. Serial No. 85,408. (No model.)

Claim.—1. An improved means for holding a ribbon, stock, or other article in place around the neck of a person, comprising a back member and a front member, each formed in one integral piece and having a plurality of retaining-fingers separated by slots through which the ribbon or other article is adapted to be passed, substantially as set forth.

2. An improved means for holding a ribbon, stock or other articles in place around the neck of a person, comprising a back member formed in one piece and having a body portion provided with a buttonhole adapted to engage the rear button of a garment and upwardly-extending fingers between which the ribbon or other article is adapted to be passed, and a front member formed in one piece provided with a buttonhole adapted to engage the front button of a garment and downwardly-extending fingers between which the ribbon or other article is adapted to be passed, substantially as set forth.

3. An improved means for holding a ribbon, stock, or other article in place around the neck of a person, comprising a back member and a front member, each having a plurality of retaining-fingers separated by slots through which the ribbon or other article is adapted to be passed, and one of said members having slits through which the band of the garment is adapted to pass, substantially as set forth.

707,480. BICYCLE. WILLIAM E. WHITELY, Springfield, Ohio. Filed Jan. 13, 1897. Serial No. 619,086. (No model.)

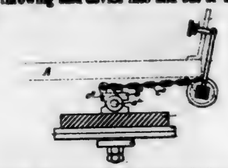


Claim.—1. A barrel or hub of a vehicle-bearing, having a straight internal screw-threaded portion, and an enlarged plain tapered portion at the end, in combination with a ball-cup screwed into said screw-threaded portion, having an enlarged plain tapered end fitting the taper of said barrel or hub, for the purpose of securely connecting said ball-cup to said barrel or hub, substantially as specified.

2. In a vehicle-bearing, a barrel or hub, a shouldered axle extending through the same, ball-cups arranged adjacent to said shoulders, and balls between said cups and shoulders, each of said ball-cups being screw-threaded on a portion of the periphery and a plain extension on the remainder of the periphery, one of said ball-cups having its plain extension tapered and the other ball-cup having its extension grooved, the barrel being formed at each end to conform to said extended portions, and means on each of said cups for turning the same into said barrels, and a set-screw adapted to engage the grooves on one of said cups, substantially as specified.

707,481. BRAKE FOR PIVOTAL RUNNING-GEAR OF VEHICLES. WILLIAM WIDDOWSON, Norristown, Pa. Filed June 6, 1902. Serial No. 110,505. (No model.)

Claim.—1. The combination of a vehicle having a body portion and running-gear, two bearing-surfaces carried by said members respectively, a pivot connecting the same, a device having means for simultaneously acting upon the pivot and one of the bearing-surfaces whereby the pressure of the bearing-surfaces upon each other may be varied, and mechanism for throwing said device into and out of action, substantially as described.



2. The combination of a vehicle having a body portion and running-gear, two bearing-surfaces carried by said members respectively, a pivot connecting the same and in positive engagement with one of said surfaces, a device for moving said pivot longitudinally and simultaneously pressing the second of the bearing-surfaces against the surface engaged by the pivot, and mechanism for operating said device to any desired extent and thereby varying the amount of friction between the two surfaces, substantially as described.

3. The combination in a vehicle having a body portion and running-gear pivotally connected together, a bearing-surface lying in a horizontal plane connected to each of said members, operating means carried by the body, and a device whereby the said pivotal connection may be moved and thereby made to vary the amount of friction between said surfaces, substantially as described.

4. The combination in a vehicle having a body portion and running-gear, a bearing-surface attached to one of said members, a pivotal piece connecting the members, a piece coacting with said bearing-surface and operated by the pivotal piece to press against the bearing-surface, with a device operative upon said pivotal piece for moving the same longitudinally and thereby controlling the movement of the body upon the running-gear, substantially as described.

5. The combination of a vehicle having a body portion and running-gear, a bearing-surface on each of said members, a bar having a projecting portion and attached to one of said members, a shaft having an eccentric portion operative upon said projecting part of the bar, a lever on the body and means for connecting the lever to said shaft whereby said eccentric-portion thereof is made to operate upon the bar and vary the amount of friction between the two bearing-surfaces when the lever is manipulated, substantially as described.

6. The combination of a body, running-gear therefor, a lever pivotally carried by the body, a shaft having an eccentric portion and a projecting arm, means for connecting the arm to the lever, pieces having bearing-surfaces carried by the body and the running-gear respectively, and a member or members operated by the eccentric portion of the shaft and operative upon one of the said pieces whereby the motion of the pieces relatively to each other may be controlled, substantially as described.

707,482. NEEDLE FOR BINDERS. EDDIE WILL, Bigstone, S. D. Filed Aug. 30, 1901. Serial No. 73,857. (No model.)

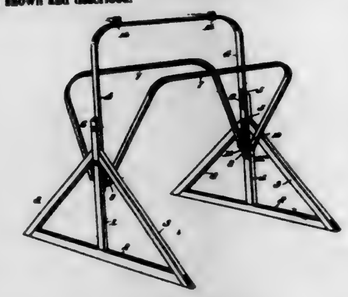
Claim.—A needle for knotting mechanism comprising an arc-shaped head and a stem formed integral from sheet metal, the metal of the head being bent upon itself to form spaced members and a connecting-web, the spaced members at the front of the head being bent inwardly into mutual contact to form a point, guide-rollers having shafts mounted in the spaced members within the head and a guide-roller mounted upon the stem.

707,488. CANOPY. FRANK C. WILMETH, Dallas, Tex. Filed Sept. 23, 1899. Serial No. 731,995. (No model.)

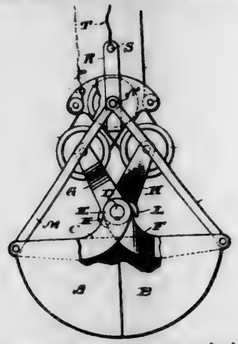
Claim.—1. A portable carriage-cover consisting of a portable frame having a base, supporting-posts secured to said base, plates 6, bows 7 journaled on said plates, a center bow adjustably secured to said supporting-frame, said plates adjustably secured to said center bow, a cover made of canvas or other suitable material, covering said frame, ropes secured to said canvas cover at the bottom of the ends thereof, pulleys secured to said center bow, said ropes passing through said pulleys and over each side of said cover substantially as shown and described.

2. A portable carriage-cover consisting of a supporting-frame, plates 6, bows 7 journaled on said plates, the center bow adjustably secured to

said supporting-frame, said plate adjustably secured to said center bow, a cover made of canvas or other suitable material, covering said frame, said cover having drop-curtains at each end, said curtains having a series of loops or rings secured thereto, pulleys secured to said center bow, operating-ropes secured to one end of said drop-curtains passing through said rings or loops and pulleys and over each side of said cover, substantially as shown and described.



707,484. HOISTING-BUCKET MECHANISM. ANDREW WIRSING, Milwaukee, Wis. Filed June 9, 1902. Serial No. 110,728. (No model.)



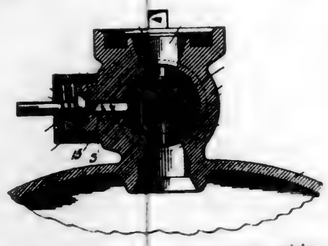
Claim.—1. A separable hoisting-bucket mechanism comprising a center spindle, crank-arms fast on the spindle, a bucket-section fast to said arms, sleeves loose on said spindle and having lower outer arms as well as inner upper arms, a bucket-section fast to the lower outer sleeve-arms, a bracket fast on the aforesaid spindle intermediate of said sleeves, an upper shell having central and end pulleys, link-rods connecting the outer corners of the bucket-sections with the shell central of the same, pulleys in suspension from the inner upper sleeve-arms and the spindle-bracket, a suspension-cable in connection with the aforesaid shell, and a draft-cable trained in contact with the several pulleys to control opening and closing of the bucket.

2. A separable hoisting-bucket mechanism comprising a center spindle, a bucket-section crank-arms rigid with the spindle, other bucket-section crank-arms loose on said spindle, upper arms radiating in opposite directions from the spindle over bucket-sections and respectively fast and loose in their connection with said spindle, pulleys in suspension from these arms, an upper shell having central and end pulleys, link-rods connecting the outer corners of the bucket-sections with the shell central of the same, a suspension-cable in connection with the aforesaid shell, and a draft-cable trained in contact with the several pulleys to control opening and closing of the bucket.

3. A separable hoisting-bucket mechanism comprising a center spindle, a bucket-section crank-arms rigid with the spindle, other bucket-section crank-arms loose on said spindle, upper arms radiating in opposite directions from the spindle over bucket-sections and respectively fast and loose in their connection with said spindle, pulleys in suspension from these arms, an upper shell having central and end pulleys, link-rods connecting the outer corners of the bucket-sections with the shell central of the same, a suspension-cable in connection with the aforesaid shell, and a draft-cable that being also in connection with the shell is trained in contact with the several pulleys to control opening and closing of the bucket.

4. A separable hoisting-bucket mechanism comprising a center spindle, a bucket-section crank-arms rigid with the spindle, other bucket-section crank-arms loose on said spindle, upper arms radiating in opposite directions from the spindle over bucket-sections and respectively fast and loose in their connection with said spindle, pulleys in suspension from these arms, an upper shell having central and end pulleys, link-rods connecting the outer corners of the bucket-sections with the shell central of the same, a suspension-cable in connection with the aforesaid shell, a draft-cable trained in contact with the several pulleys to control opening and closing of the bucket, and meeting stops on the arms that radiate in opposite directions over said bucket-sections.

707,485. SAFETY-VALVE. WILLIAM WIBKART and BRUNO SEIDEL, Chicago, Ill., assignors to the Adams & Westlake Company, a Corporation of Illinois. Filed Oct. 25, 1901. Serial No. 79,968. (No model.)



Claim.—1. In an apparatus for generating or containing a fluid under pressure, in combination, a normally closed relief-valve, a movable element independent of the valve and which is an essential part of the generating or other apparatus, and an operative connection between the movable element and the valve whereby the said valve is tripped at each operation of the movable element.

2. In an apparatus for generating or containing a fluid under pressure, in combination, a spring-closed relief-valve, a movable element of the apparatus and which is independent of the valve, and an adjunct of the valve in the path of and which is tripped by the movable element during its ordinary operation to move the valve from its seat.

3. The combination of a pipe or nipple, a port in the wall thereof, a valve normally closing the port, a valve in the pipe or nipple, and means tripped by the latter valve for moving the former from its seat.

4. The combination of a pipe or nipple, a port in the wall thereof, a reciprocating valve normally closing the port, an oscillating valve in the pipe or nipple, and means tripped by the oscillating valve for moving the reciprocating valve from its seat.

5. The combination of a pipe or nipple, a port in the wall thereof, a spring-pressed valve normally closing the port, an oscillating valve in the pipe or nipple, a passage in the oscillating valve leading to the port, and a stem projecting from the port-valve and which is tripped by the oscillating valve to move the port-valve from its seat.

6. The combination of a pipe or nipple, a port in the wall thereof, a spring holding the valve normally closed, a stem projecting from the valve and into the passage of the pipe, an oscillating valve in the pipe and which engages the stem to move the port-valve from its seat, a passage through the oscillating valve communicating with the port in the wall of the pipe, and a recess in the oscillating valve to receive the end of the valve-stem when the oscillating valve is open.

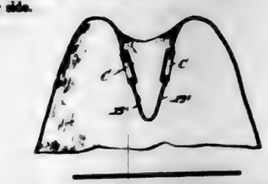
7. In a generating-tank, the combination with a spring-closed blow-off valve, of a part movable in bringing the generator into service, and connection between such valve and movable part for unseating the valve as such part is moved.

8. In a generating-tank, in combination, a valve controlling the throat of the tank, a blow-off port, and a spring-closed valve therefor, the controlling-valve being provided with a tripping adjunct engaging the blow-off valve.

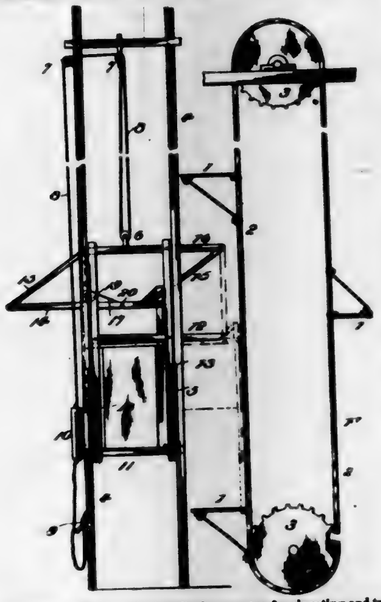
9. In an apparatus for generating or containing a fluid under pressure, in combination, a spring-closed relief-valve, a movable element of the apparatus independent of the valve, and a valve-unseating trip in the path of the movable element.

707,486. VENTILATED HAT. JULIUS WOLBRIGHT, Manila, Philippine Islands. Filed Jan. 22, 1902. Serial No. 90,795. (No model.)

Claim.—A hat having a soft crown and provided in the top of said crown on opposite sides of a median line drawn from front to rear with ventilators arranged approximately midway between the front and rear edges of the crown, whereby when the hat is creased from front to rear in alpine form the ventilators will be within the crease and in the opposite walls thereof approximately midway between the front and rear sides of the crown and will be obscured and in position to receive air coming from either side.



707,487. APPARATUS FOR ELEVATING OR CONVEYING AND TRANSFERRING ICE, &c. EDGAR A. WRIGHT, Canton, Ohio, assignor to the Aultman Company, Canton, Ohio, a Corporation of Ohio. Filed Feb. 15, 1900. Serial No. 4,370. (No model.)



Claim.—1. The herein-described apparatus for elevating and transferring or storing ice, consisting of the combination of an elevator and an automatic transferring device having means for engaging the ice at its farther side for removing the ice from said elevator.

2. In an apparatus for elevating and transferring ice, and for other purposes, the combination of an elevator, a receiving means within the storage-chamber or otherwise suitably situated, and an automatic laterally-acting transferring device having means for engaging the ice on its farther side while on said elevator, to remove it therefrom, and transfer it to said receiving means.

3. The combination of an elevator, a cage for receiving the ice from said elevator movable in the direction of movement of the ice, a means for engaging and transferring the ice carried by said cage and operated by the movement of the cage, a bar or stop carried by the cage and adapted to be engaged by the ice, and means for receiving the ice from said cage.

4. The combination of an elevating or conveying means, a receiving-cage having a tilting platform, means for automatically transferring the ice from said conveying means to said platform, and means for tilting said platform automatically to deliver the ice.

5. The combination with an elevating or conveying means, a receiving-cage having a tilting platform hinged on said cage and connected with a fixed point, means for engaging and transferring the ice from said conveying means to said platform operated by the movement of the cage, and a bar or stop carried by the cage and adapted to be engaged by a part moved by said elevating means to operate said cage.

6. The combination with the storage-chamber having a receiving-opening *a* of a frame situated near said opening, a cage movable in said frame, an elevator, and means for automatically transferring the ice from said elevator to said cage, and means for automatically delivering the ice from said cage through said opening.

7. The combination of the storage-chamber having a series of openings *a* one above the other, a frame extending by said openings, a cage movable in said frame and adjustable with respect to each of said openings, an elevating or conveying device, means for automatically transferring the ice from said conveying device to said cage, and means for automatically delivering the ice from said cage to one of said openings.

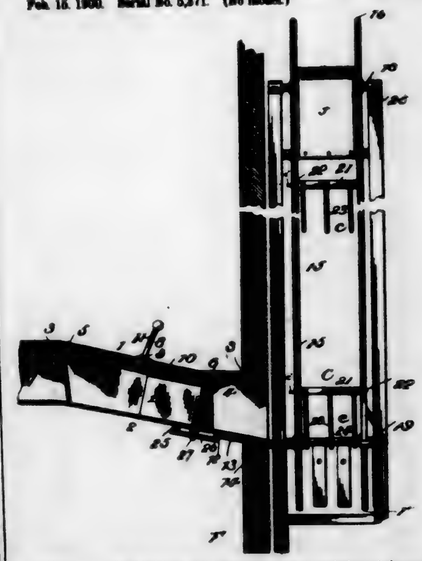
8. The combination of a storage-chamber having an opening *a*, a frame extending by said opening, a receiving-cage movable in said frame, an automatic transferring device adapted to engage the ice and movable toward and from the cage, means for delivering the ice from the cage to said opening, and a conveying or elevating means adapted to carry the ice and acting to actuate said transferring device.

9. The herein-described apparatus for elevating and transferring or storing ice, consisting of the combination of an elevator and an automatic reciprocating transferring device having means for engaging the ice at its farther side for removing the load from said elevator.

10. The herein-described apparatus for elevating and transferring or storing ice, consisting of the combination of a receiving-elevator, a discharging-elevator and a reciprocating automatic transferring device operated by the movement of one of said elevators and acting to remove the load from the receiving-elevator and permit its transfer to the discharging-elevator.

11. The herein-described apparatus for elevating and transferring or storing ice, consisting of the combination of an elevator, an automatic transferring and draft device having means for positively engaging the ice to draw the same from the elevator platform or support, and means whereby the movement of the elevator is caused to actuate said device.

707,488. APPARATUS FOR ELEVATING OR CONVEYING AND TRANSFERRING ICE, &c. EDGAR A. WRIGHT, Canton, Ohio, assignor to the Aultman Company, Canton, Ohio, a Corporation of Ohio. Filed Feb. 15, 1900. Serial No. 5,371. (No model.)



Claim.—1. The herein-described apparatus consisting of the combination with a storage-chamber, of an air-lock having inner and outer doors and an intermediate ice-space, and an elevating or conveying means within said chamber for receiving ice or other material from said lock.

2. The combination with a storage-chamber, of an air-lock having inner and outer doors and an intermediate ice-space, and an elevating or conveying means within the chamber acting to open said lock and adapted to receive the ice or other material therefrom.

3. The combination with a storage-chamber, of an inclined air-lock having inner and outer doors and an intermediate ice-space, and an endless conveying or elevating device within the chamber and acting to receive the ice or other material from said lock.

4. The combination with a storage-chamber, of an air-lock, a means for loosening a cake of ice therein, and an elevating or conveying means within said chamber acting to operate said loosening means and adapted to receive the ice or other material from said lock.

5. The combination of a conveying or elevating means, an inclined chute or platform, a device for loosening a cake of ice or other material therefrom, and an actuating means whereby the conveyer or elevator operates said loosening device.

6. The combination, with the elevator having a carrier provided with a space or spaces, of a discharging device having a supporting arm or arms in line with said spaces, and means for adjusting said discharging device bodily longitudinally of the elevator.

7. The combination with the elevator C, of the chute 1 having an air-lock with inner and outer doors and an intermediate ice-space and an indicator 8, having an arm extending into said lock between the doors.

8. The combination of the elevator C having carriers provided with hooks 23, the support 24, the chute having an air-lock and adapted to deliver a cake of ice to said support, and a vertically-adjustable discharging device D.

9. The combination of the storage-chamber, an elevator within the same, means for directing the ice through the wall of said chamber to the elevator comprising a passage-way, a door or stop for holding the ice, a latch or fastening device for said door, and means whereby the elevator releases said latch.

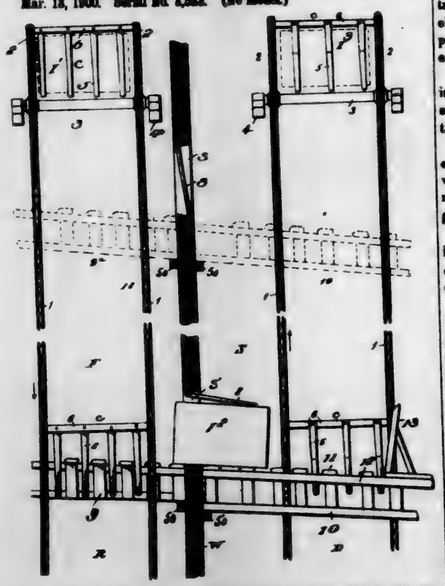
10. The combination with the endless elevator and the swinging carriers *c*, of the shield J arranged between the upper wheels or pulleys of said elevator and adapted to engage the under side of the carriers.

11. The combination of an endless elevator comprising two chains or members, a swinging carrier *c* suspended and adapted to swing between said members and having its line of pivotal connection with the elevator situated at one side of the load-supporting portion of the carrier, means for discharging the load situated longitudinally of the elevator in line with said carrier, and a guide for holding said carrier out of its normal suspended position and in line with the discharging means.

12. The combination of an elevator having a carrier provided with a space or spaces and a discharging device having an arm or arms in line with said spaces and inclined in a direction toward the end of said carrier.

13. The combination of an elevator having a carrier provided with a space or spaces, a discharging device having an arm or arms in line with said spaces, and inclined in a direction toward the end of said carrier, and guides in which said discharging device is adjustable longitudinally of the elevator.

707,489. APPARATUS FOR ELEVATING OR CONVEYING AND TRANSFERRING ICE, &c. EDGAR A. WRIGHT, Canton, Ohio, assignor to the Aultman Company, Canton, Ohio, a Corporation of Ohio. Filed Mar. 13, 1900. Serial No. 8,562. (No model.)



Claim.—1. The herein-described elevating or conveying and transferring apparatus comprising a receiving-elevator, a delivering-elevator and means in a position intermediate between the ends of the receiving-elevator for transferring the load from the former to the latter.

2. The herein-described elevating or conveying and transferring apparatus comprising a receiving-elevator, a delivering-elevator and means for transferring the load from the former elevator to the latter, such means being adjustable relative to both said elevators, substantially as set forth.

3. The combination of an endless elevator or carrier, a second endless elevator or carrier, and means for transferring the load from the descending leg of the first elevator to the ascending leg of the second elevator, said transferring means being adjustable relative to both said elevators.

4. The combination with the storage-chamber 8 having a wall provided with a contracted opening, an elevator or carrier without said wall, a second elevator, or carrier on the inside of said wall, and means for transferring the load from the first elevator through said opening to the second elevator, in a direction substantially transverse to that which is imparted to the load by the first elevator.

5. The combination with the storage-chamber 8, having a wall provided with a contracted opening, an endless elevator or carrier without said wall, a second endless elevator or carrier on the inside of the said wall, and means for transferring the load from the first elevator through said opening to the second elevator, in a direction substantially transverse to that imparted to the load by the first elevator.

6. The combination of the receiving elevator or carrier, an automatic discharging device by which the load is taken from said elevator, a second elevator or carrier, a receiver adapted to support the load and arranged between the ends of the second elevator or carrier and from which the latter is adapted to take the load, and means for transferring the load from said discharging device to said receiver.

7. The combination of an endless receiving-elevator, an automatic discharging device arranged between the ends of said elevator by which the load is taken from said elevator, a second endless elevator, a receiver from which the latter is adapted to take the load, and means for transferring the load from said discharging device to said receiver.

8. The combination with the storage-chamber 8 having a wall provided with an opening, of an endless elevator without said wall, an automatic discharging device situated adjacent to the said opening by which the load is taken from said elevator, a second endless elevator within said chamber, a receiver from which the latter is adapted to take the load, and means for transferring the load from said discharging device through said opening to the receiver.

9. The combination with a storage-chamber having a wall provided with an opening through which the material elevated is adapted to be passed; of an endless elevator having its ascending and its descending legs arranged in a plane substantially parallel with the wall, and means for transferring the load from the elevator situated between the ends of the elevator and arranged to move the load in a direction transverse to the plane in which the elevator moves, a portion of said transferring means extending within the path of parts of the elevator.

10. The combination of a receiving-elevator provided with swinging carriers having hooks 5, a discharging-elevator having substantially similar carriers *c*, and means for transferring the load from said hooks of the receiving-elevator to said hooks of the discharging-elevator.

11. The combination of a plurality of elevators each comprising two elevating-chains, suitable carriers thereon, and two independent chain-wheels, a gear-wheel connected with each of said chain-wheels, a connecting-shaft extending past both elevators and pinions on said shaft engaging the gear-wheels of all of said chain-wheels.

12. The combination with an elevator having endless chains, swinging carriers thereon, and separate chain-wheels at the upper terms of said chains, gear-wheels connected respectively with the chain-wheels, and a connecting-shaft having a pinion for each of said gear-wheels.

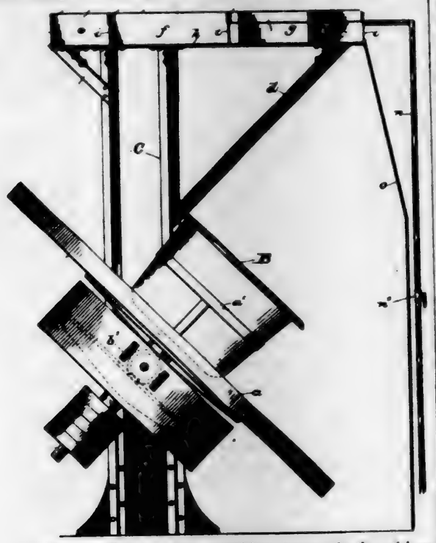
13. The combination, in an elevator, of the endless chains or connections, swinging carriers thereon arranged to swing between the chains or connections, and the guides 18 for the carriers arranged to hold them out of their normal position and in proper position to receive a load, substantially as set forth.

707,490. ENAMEL-SIFTING APPARATUS. CARL H. EWERHARD, Baltimore, Md. Filed May 13, 1902. Serial No. 107,122. (No model.)

Claim.—1. An enameling apparatus, comprising a tiltable and rotatable table to support the article to be enameled; a plurality of sifting-boxes adapted to contain enamel and mounted above said table and each box free from direct connection with the other boxes; and independent jarring means for each box, as set forth.

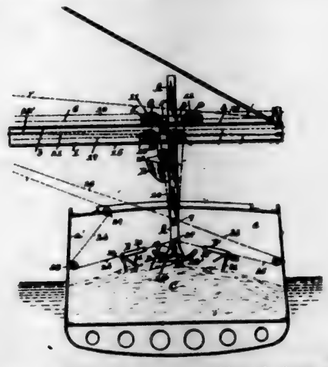
2. An enameling apparatus, comprising a tiltable and rotatable table for the support of the article to be enameled; standards rising above said table; a frame supported on said standards; a plurality of sifting-boxes mounted in said frame and free from direct connection with each other; and an independent jarring device for each of said boxes, as set forth.

3. An enameling apparatus, comprising a support for the article to be enameled; a frame above said support; a plurality of sifting-boxes mounted in said frame and free from direct connection with each other; and an independent jarring device for each of said boxes, as set forth.



4. An enameling apparatus, comprising a support for the article to be enameled; standards rising above said support; a frame of angle material supported on said standards; a plurality of stationary sifting-boxes mounted and supported within said frame, said boxes being contiguous to each other, but free from direct connection with each other; and an independent jarring device for each of said boxes as set forth.

707,491. APPARATUS FOR REMOVING MATERIALS FROM BOATS, &c. ALFRED M. ADELIS, Pittsburg, Pa. Filed Mar. 17, 1902. Serial No. 98,622. (No model.)



Claim.—1. A hoisting apparatus comprising a bucket or scoop suspended by a cable, and a swinging frame normally free from but adapted to engage with said bucket to move and fill the same.

2. A hoisting apparatus comprising a swinging frame, and a bucket or scoop suspended by a cable from a trolley and adapted to come in contact with and be moved by said frame and be filled by the swinging of said frame.

3. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, and means within said hold adapted to come in contact with said bucket to swing the same and gather the material therein.

4. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, and means within said hold adapted to engage with said bucket as it is lowered into the hold to tilt and swing the same to gather the material therein.

5. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, and a swinging frame extending within said hold adapted to engage with said bucket as it is lowered into the hold to tilt and swing the same to gather the material therein.

6. The combination with a boat, of a bucket having projections thereon and adapted to be lowered and raised to and from the hold of said boat, and a swinging frame within said hold adapted to engage with the projections on said bucket as it is lowered into the hold to tilt and swing the same to gather the material therein.

7. The combination with a boat, of a bucket having projections thereon and adapted to be lowered and raised to and from the hold of said boat, and a swinging frame within said hold having slots therein adapted to engage with the projections on said bucket as it is lowered into the hold to tilt and swing the same to gather the material therein.

8. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket as it is lowered into the hold to tilt and swing the same to gather the material therein, and means for swinging said frame.

9. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket as it is lowered into the hold to tilt and swing the same, and means within the hold of said boat for swinging said frame.

10. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, and a cable within said hold and connected to said swinging frame to swing the same.

11. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, and a cable within said hold passing around sheaves therein and connected to said swinging frame to swing the same.

12. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold, and projections on said bucket adapted to engage with seats or slots in said frame to tilt said bucket and swing it to gather the material therein.

13. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold, and projections on said bucket adapted to engage with curved seats or slots in said frame to tilt said bucket and swing it to gather the material therein.

14. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame having side members within said hold, projections on said bucket adapted to engage with seats or slots in the lower end of said side members, and a hinged or pivoted portion on the lower end of said side members containing said seats or slots.

15. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame having side members within said hold, projections on said bucket adapted to engage with seats or slots in the lower end of said side members, a hinged or pivoted portion on the lower end of said side members containing said seats or slots, and a bar pivoted to said hinged portion and engaging by a slot therein with a pin on the side members.

16. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, and scraping devices within said hold adapted to move with said frame and scrape the material toward the bucket.

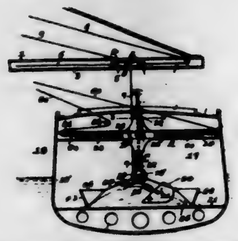
17. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, a cable within said hold and connected to said frame for swinging the same, and scraping devices on said cable adapted to move with the frame and scrape the material toward the bucket.

18. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, a cable within said hold and connected to said frame for swinging the frame, frames on said cable, and a hinged or pivoted scraper on said frames adapted to move with said swinging frame and scrape the material toward the bucket.

19. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat, a swinging frame within said hold adapted to engage with said bucket to tilt and swing the same to gather the material therein, a cable within said hold and connected to said frame for swinging the same, frames on said cable, a hinged or pivoted scraper on said frames adapted to move with said swinging frame

and scrape the material toward the bucket, and a step on said frames adapted to hold said scraper in position for operating.

707,492. APPARATUS FOR REMOVING MATERIALS FROM BOATS, &c. ALFRED M. ACKLEY, Pittsburg, Pa. Filed Mar. 19, 1902. Serial No. 98,914. (No model.)



Claim.—1. The combination of a runway, a trolley thereon, a rising and falling bucket adapted to raise material and having its support independent of said trolley, said trolley being adapted to engage the bucket-cables to assist in gathering the material therein.

2. The combination of a bucket adapted to raise material and to be lowered and raised by suspending-lines, a runway or frame, and a trolley on said frame normally free but adapted to engage said suspending-lines to move said bucket and gather the material therein.

3. The combination with a boat, of a bucket adapted to be lowered and raised to and from the hold of said boat and elevate material therefrom, a runway or frame, and a trolley movable on said frame and normally free from but adapted to engage with said bucket to move the same and assist in gathering the material therein.

4. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said hold, and a trolley on said frame adapted to move or travel thereon to engage with said bucket to move the same and gather the material therein.

5. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, and a frame on said trolley adapted to move or travel therewith to engage with said bucket to move the same and gather the material therein.

6. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, and an adjustable frame on said trolley adapted to move or travel therewith to engage with said bucket to move the same and gather the material therein.

7. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said hold, a trolley on said frame adapted to move or travel thereon, and a frame on said trolley adapted to be raised and lowered in guides therein and move or travel with said trolley to engage with the bucket to move the same and gather the material therein.

8. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said hold, a trolley on said frame adapted to move or travel thereon to engage with said bucket to move the same and gather the material therein, and means for moving said trolley.

9. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon to engage with said bucket to move the same and gather the material therein, and a power-driven rope or cable connected to said trolley for moving the same.

10. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, a frame on said trolley adapted to be raised and lowered in guides therein and move or travel with said trolley to engage with the bucket to move the same and gather the material therein, and means for raising and lowering said last-named frame.

11. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, a frame on said trolley adapted to be raised and lowered in guides therein and move or travel with said trolley to engage with said bucket to move the same and gather the material therein, a screw-bar supported within said last-named frame, and means engaging with said screw-bar for raising and lowering said last-named frame.

12. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, a frame on said trolley adapted to be raised and lowered in guides therein and move or travel with said trolley to engage with said bucket to move the same and gather the material therein, a screw-bar supported within said last-named frame, a nut engaging with said screw-bar, and means engaging with said nut to turn the same and raise or lower said last-named frame.

13. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to be raised and lowered in guides therein and move or travel with said trolley to engage with said bucket to move the same and gather the material therein, a screw-bar supported within said last-named frame, a nut engaging with said screw-bar and provided with a gear-face thereon, a gear-wheel mounted on a rod and engaging with said gear-face, and a handle on said rod for turning the same to raise and lower said last-named frame.

14. The combination with a boat, of a scoop or bucket adapted to be lowered and raised by power-driven cables to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move or travel thereon, a frame on said trolley adapted to move or travel therewith, and sheaves on the lower end of said last-named frame adapted to engage with the said bucket-cables to tilt and move said bucket to gather the material therein.

15. The combination with a boat, of a scoop or bucket, a bracket on the bail of said bucket, sheaves on said bracket, power-driven cables passing around said sheaves to raise and lower said bucket to and from the hold of said boat, a frame within said boat, a trolley on said frame and adapted to move or travel thereon, a frame on said trolley adapted to move or travel therewith, and sheaves on the lower end of said last-named frame adapted to engage with said bucket-cables to tilt and move said bucket to gather the material therein.

16. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move and travel thereon, a frame on said trolley adapted to move and travel therewith to engage with said bucket to move the same and gather the material therein, and scrapers connected to and adapted to move with said last-named frame to scrape the material toward the bucket.

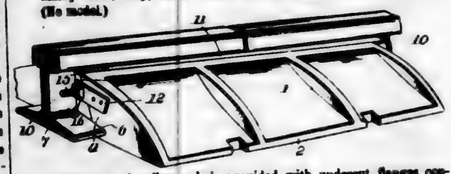
17. The combination with a boat, of a scoop or bucket adapted to be lowered and raised to and from the hold of said boat, a frame within said boat, a trolley on said frame adapted to move and travel thereon, a frame on said trolley having vertical standards thereon and adapted to move and travel with said trolley, said standards adapted to engage at their lower ends with said bucket to move the same and gather the material therein, and a scraper on each side of said standards and connected to the lower end thereof to scrape the material toward the bucket.

707,493. DETONATING COMPOUND. UGO ALVISI, Rome, Italy. Original application filed Dec. 17, 1898, Serial No. 699,562. Divided and this application filed Oct. 10, 1901. Serial No. 78,345. (No specimens.)

Claim.—1. A detonating compound containing fulminate of mercury and perchlorate of ammonium.

2. A detonating compound containing 17.20 per cent. of perchlorate of ammonium and 82.80 per cent. of fulminate of mercury.

707,494. RAIL-JOINT FOR RAILWAYS. EDWARD R. AVERY, Peny, Mont., assignor of one-half to Charles Elmer Morris and Philip Harry Gohn, Peny, Mont. Filed Apr. 30, 1902. Serial No. 105,335. (No model.)



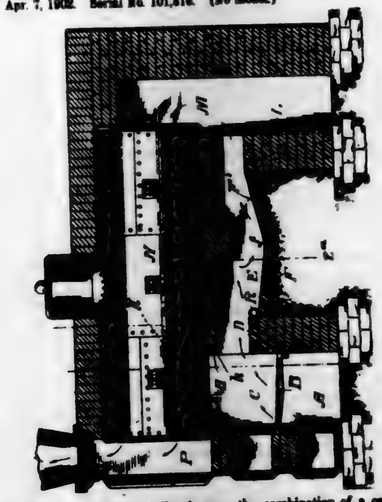
Claim.—1. A railway-chair provided with undercut flanges constructed to embrace the base-flanges and webs of two abutting rails, one of said flanges being parallel with the rail-webs and the other oblique thereto, a wedge-shaped key fitted between said oblique flange and the rails, a slotted resilient bracket-plate fitted to the end of the oblique flange, a bolt fitted in the smaller end of the wedge-shaped key and projecting through the slot in the spring bracket-plate and a nut fitted on the bolt and bearing against the spring bracket-plate, substantially as described.

2. A railway-chair provided with undercut flanges constructed to embrace the base-flanges and webs of two abutting rails, one of said flanges being parallel with the rail-web and the other oblique thereto, a wedge-shaped key fitted between said oblique flange and the rails, a slotted resilient bracket-plate fitted to the end of the oblique flange, a bolt removably fitted in the smaller end of the wedge-shaped key and projecting through the slot in the spring bracket-plate, and a nut fitted on the bolt and bearing against the spring bracket-plate, substantially as described.

3. A railway-chair provided with undercut flanges constructed to embrace the base-flanges and webs of two abutting rails, one of said flanges being parallel with the rail-webs and the other oblique thereto, a wedge-shaped key fitted between said oblique flange and the rails, a slotted resilient bracket-plate fitted to the end of the oblique flange and projecting inwardly in front of the smaller end of the wedge-shaped key, a bolt fitted in the smaller end of said wedge-shaped key and projecting through the slot in the spring bracket-plate, and a nut fitted on the bolt and bearing against the spring bracket-plate, substantially as described.

4. A railway-chair provided with undercut flanges constructed to embrace the base-flanges and webs of two abutting rails, one of said flanges being parallel with the rail-web, and the other oblique thereto, a wedge-shaped key fitted between said oblique flange and the rails, a slotted resilient bracket-plate fitted to the end of the oblique flange and projecting inwardly in front of the smaller end of the key, said key being provided on the inner face of its smaller end with a T-shaped groove, a headed bolt removably seated in said groove and projecting through the slot in the spring bracket-plate, and a nut fitted on said bolt and bearing against the spring bracket-plate, substantially as described.

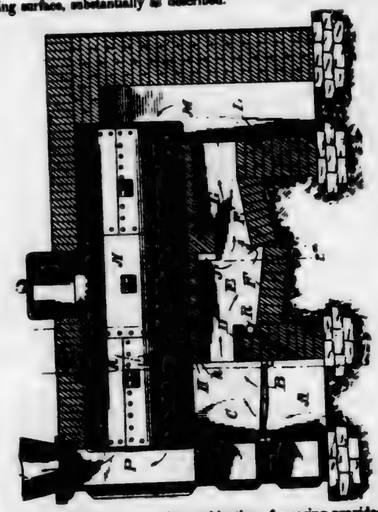
707,495. STEAM-BOILER FURNACE. JOHN B. BAILEY, Baltimore, Md., assignor to Maurice Lamphelmer, Baltimore, Md. Filed Apr. 7, 1902. Serial No. 101,816. (No model.)



Claim.—In a steam-boiler furnace, the combination of a casing, a fuel-chamber at one end thereof, a front bridge-wall behind said chamber, a combustion-chamber having a concave bottom behind said bridge-wall, a rear bridge-wall at the other end of said chamber, a boiler mounted in said casing and extending over said fuel-chamber and said bridge-walls, an arch extending from the front of said front bridge-wall to the rear of said rear bridge-wall and tangent to said boiler at its highest point, a partition-wall resting upon the front of said arch and extending up to and inclosing the lower part of said boiler, a baffle-wall extending downwardly from about the center of said arch toward the lowest part of said combustion-chamber, and a perforated air-pipe behind said front bridge-wall and adapted to supply air to the products of combustion after they have left the fuel-chamber, substantially as described.

707,496. STEAM-BOILER FURNACE. JOHN B. BAILEY, Baltimore, Md., assignor to Maurice Lamphelmer, Baltimore, Md. Filed Apr. 7, 1902. Serial No. 101,817. (No model.)

Claim.—1. In a steam-boiler furnace, the combination of a fuel-chamber, front and rear bridge-walls, a combustion-chamber between said walls provided with an inclined floor, an arch extending over said walls, a boiler located above said arch and contacting with its highest point, and a baffle-plate extending downwardly from about the center of said arch, said baffle-plate being provided with recesses or pockets on its front projecting surface, substantially as described.

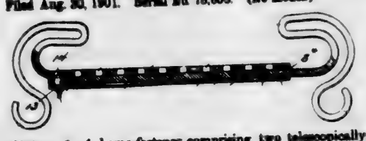


2. In a boiler-furnace, the combination of a casing provided with a fuel-chamber near one end, front and rear bridge-walls, an arch extending completely over said bridge-walls and supported by the sides of the casing, a boiler extending over said fuel-chamber and touching said arch at its highest point, a wall or partition extending upwardly from the front of said arch and around the lower part of said boiler, and a baffle-plate extending downwardly from substantially the center of said arch and provided with recesses or hollows on its front face, substantially as described.

3. In a boiler-furnace, the combination of a casing, a fuel-chamber near one end thereof, front and rear bridge-walls, a double inclined floor extending between said bridge-walls, one part of said floor being higher than the other so as to form a retarding-corner, an arch sprung from the side walls of said casing and extending over said bridge-walls, a boiler mounted in said casing and extending over said fuel-chamber and said arch and touching the highest point of said arch, a partition extending upwardly from the front of said arch and inclosing the lower part of said boiler, and a baffle-plate located near the center of said arch and extending downwardly, said baffle-plate being provided with hollows or recesses on its forward face and being located above the corner in the floor between said bridge-walls, substantially as described.

4. In a boiler-furnace, the combination of a casing, a fuel-chamber near one end thereof, front and rear bridge-walls, a double inclined floor, extending between said bridge-walls, one part of said floor being higher than the other so as to form a retarding-corner, an arch sprung from the side walls of said casing and extending over said bridge-walls, a boiler mounted in said casing and extending over said fuel-chamber and said arch and touching the highest point of said arch, a partition extending upwardly from the front of said arch and inclosing the lower part of said boiler, a baffle-plate located near the center of said arch and extending downwardly, said baffle-plate being provided with hollows or recesses on its forward face and being located above the corner in the floor between said bridge-walls, and a perforated air-pipe located behind the front bridge-wall and adapted to supply air to the products of combustion after they have left the fuel-chamber, substantially as described.

707,497. HAME-FASTENER. ERNEST G. ERNEST, Atlanta, Ga. Filed Aug. 20, 1901. Serial No. 73,858. (No model.)



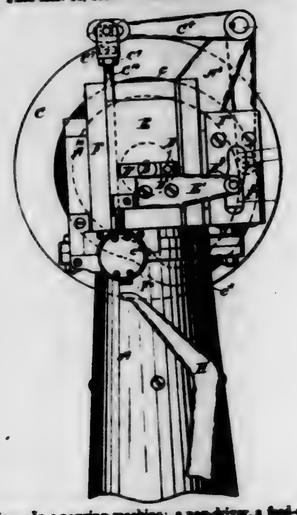
Claim.—1. A hame-fastener comprising two telescopically-related plates each having an outer terminal hook device, the one plate being

provided with a series of openings and the other plate having a revolubly spring-controlled dog slidingly mounted therein adjacent to one end, the dog having a clearance at its upper extremity to permit the one plate to slide thereover in varying the adjustment.

2. A hame-fastener comprising two plates with outer terminal hook devices, the one plate being superimposed on the other and both plates telescopically related, the one plate having a series of separated openings therethrough in longitudinal alinement, a dog revolubly and slidingly mounted in the other plate and normally projected through one of the openings of the first plate, said dog having a clearance structure at its upper extremity to permit the upper plate to slide thereover in varying the adjustment of the two plates, and a spring secured to the plate carrying the dog and having a bifurcated end in engagement with the latter.

3. A hame-fastener comprising an outer perforated plate having its edges bent inward to form grooves, and one of its ends bent inward, then outward, and downward to form a hook, to engage a ring, and a depending finger-piece, an inner plate adjustably supported in said grooves and formed with an opening, and having one of its ends bent inward, then outward and downward to form a hook to engage a ring, and a depending finger-piece, and a spring-pressed dog extending through said opening.

707,498. PEGGING-MACHINE. JOHN F. BERRYMAN, Whitman, Mass. Filed Mar. 16, 1901. Serial No. 51,552. (No model.)

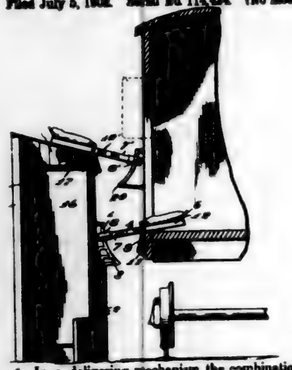


Claim.—In a pegging-machine; a peg-driver, a feed-plate mounted for lateral movement in the machine-head, feed devices carried by said feed-plate, an awl-plate mounted for vertical movement in said feed-plate, an awl carried by said awl-plate, means to vertically reciprocate said awl-plate, a laterally-projecting arm on said awl-plate, a cam-roll carried by said arm, a plate attached to the machine-head and provided with an adjustable cam-groove, whereby, as said awl-plate is vertically reciprocated, it and the feed-plate will be given a simultaneous lateral movement to feed the work, the extent of said feed movement being dependent upon the adjustment of the cam-groove, substantially as and for the purpose set forth.

707,499. NUT-LOCK. JOHN P. BERRYMAN, Lexington, Va., assignor to David G. Humphreys, trustee, Lexington, Va. Filed Dec. 14, 1901. Serial No. 86,078. (No model.)

Claim.—A nut-lock comprising in combination with the nut having a recess in one of its faces adjacent to the object to which the lock is applied, the walls of said recess tapering near its outer end, a flexible locking-pin mounted loosely in said recess, its free end projecting a slight distance beyond the outer end of the recess adapted to contact with an object to cause the pin to buckle in opposite directions accordingly as the nut is screwed upon or unscrewed from a bolt, as set forth.

707,500. MAIL RECEIVING AND DELIVERING MECHANISM FOR RAILWAYS. FRANKLIN H. BURR, Atlantic, Iowa, assignor to Fast Mail Delivery Company, Council Bluffs, Iowa, a Corporation of South Dakota. Filed July 5, 1902. Serial No. 114,494. (No model.)



Claim.—1. In a delivering mechanism the combination of a supporting-frame, means for pivotally supporting the said frame, the said pivotal mechanism being capable of lengthening the throw of the frame, and means for automatically swinging said frame upon its pivotal support, substantially as described.

2. In a delivering mechanism, the combination of a delivering-frame, an intermediate, pivotally-mounted link pivotally carrying the same for increasing the throw of the frame, both of the pivots being positioned in the same vertical plane, and means for swinging the frame upon said link, substantially as described.

3. In a delivering mechanism, the combination with a delivering-frame, comprising a suitable framework and a bail for forming an abutment at one end thereof to prevent pouches being thrown from the frame by centrifugal force, means pivotally supporting said delivering-frame, and means for swinging the delivering-framework upon its pivot, substantially as described.

4. In a delivering mechanism, the combination of a delivering-frame comprising a suitable framework, a pivotally-mounted apron carried thereby, and an abutment formed at the end of the framework, pivotal means supporting said delivering-frame capable of lengthening the throw thereof, and means for swinging said delivering-frame upon its pivot, substantially as described.

5. In a delivering mechanism, the combination of a car, an intermediate link pivotally attached thereto, a delivering-frame pivoted to said link, and means fixed relative to said car for swinging said delivering-frame upon said link and its pivot, substantially as described.

6. In a delivering mechanism, the combination of a delivering-frame pivoted to the car, means for swinging said frame upon its pivot, a suitable shield fixed at an angle relative to the car, and a housing contiguous to said shield for receiving an article delivered by said frame, substantially as described.

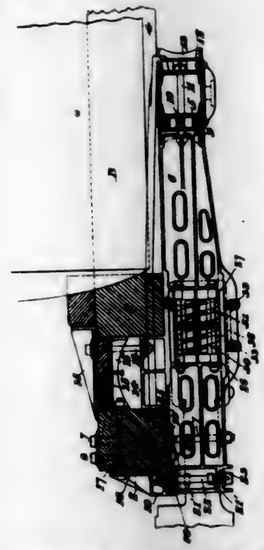
7. In a delivering mechanism the combination of a frame larger at one end than at the other and contracted within its central portion, a pivoted-link frame pivoted to said delivering-frame at its contracted part, the said pivoted-link frame being also pivoted to a suitable support, a tilting arm projecting from the said delivering-frame, and means for engaging the same to throw the frame upon its pivotal point, the pivotal-link frame lengthening the throw and action of the said arm, substantially as described.

707,501. DRAFT-RIGGING. WALTER H. COFFIN, Cleveland, Ohio, assignor to the National Malleable Castings Company, Cleveland, Ohio, a Corporation of Ohio. Filed Jan. 16, 1902. Serial No. 90,054. (No model.)

Claim.—1. The combination of draft-irons, end sill and head-block, of separating-blocks formed on the draft-irons, fitting between the end sill and head-block; substantially as described.

2. The combination of the head-block and end sill, and a frame set on these parts and having a separating portion which fits between them, and having also a lateral socket to receive a deck-board; substantially as described.

3. The combination with an end sill, of a buffing-plate formed with a central buffer, and with lips 20 at each side of the buffer adapted with the buffer to constitute spaces for the draft-irons which bear at one side against the buffer and at the other side against the lips; substantially as described.



4. The combination with an end sill, of a buffing-plate formed with a central buffer, and with lips 20 at each side of the buffer adapted with the buffer to constitute spaces for the draft-irons which bear at one side against the buffer and at the other side against the lips, said buffing-plate having laterally-projecting portions extending along the end sills and adapted to distribute the buffing blows; substantially as described.

5. The combination with the draft-irons, of chafing-blocks removably set on the opposite inner faces of the draft-irons, said chafing-blocks having transverse lugs and vertical bolts passing through the lugs and securing them to the draft-irons; substantially as described.

6. The combination with the draft-irons, of chafing-blocks removably set on the opposite inner faces of the draft-irons, said chafing-blocks having lugs and bolts passing through the lugs and securing them to the draft-irons, and a carry-iron also held by said bolts; substantially as described.

7. The combination with the end sill, of a buffing-plate applied thereto and having a flange extending under the end sill, and a draft-iron fitting under said flange and against the same, a space being afforded between the edge of said flange and a shoulder on the draft-iron for adjustment; substantially as described.

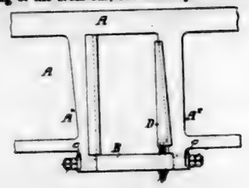
8. The combination of a draft-iron having a lateral opening or window for removal of the springs, a draw-bar and a yoke having its arms above and below the spring mechanism, and a carry-iron supporting the yoke; substantially as described.

9. The combination of a draft-iron having a lateral opening or window for removal of the spring, a draw-bar, a yoke having arms above and below the spring affording a lateral opening for its removal, and a carry-iron supporting the yoke and having cheeks which constitute lateral bearings for the yoke; substantially as described.

707,502. PEDESTAL FOR LOCOMOTIVES. THOMAS R. COLLINS, Philadelphia, Pa., assignor to George Burnham, William P. Henneay, John H. Converse, William L. Austin, Samuel M. Vauclain, Alba B. Johnson, and George Burnham, Jr., doing business under firm-name of Burnham, Williams and Company, Philadelphia, Pa. Filed Dec. 13, 1900. Serial No. 39,754. (No model.)

Claim.—1. The combination of a pedestal having side members provided with slots in their lower ends, a cross-bar mounted between said members having threaded extensions constructed to enter said slots, nuts for said threaded extensions, a wedge mounted on one of the pedestals, and a screw in movable engagement with said wedge, passing through a threaded opening in said cross-bar, said screw having an irregular head whereby it may be turned, substantially as described

2. The combination of a pedestal, side members having slots in their lower ends, a cross-bar mounted between said side members having screw-threaded extensions for engaging said slots, nuts and washers on the extensions whereby said cross-bar is retained in position, one of said extensions being shaped to fit the slot in one of the side members, so as to prevent the turning of the cross-bar, substantially as described.



707,503. GRAVE-FILLER. URIAH H. DERRING, Cleburne, Tex., assignor of one-half to Jacob D. Olger, Cleburne, Tex. Filed Dec. 24, 1901. Serial No. 87,069. (No model.)

Claim.—1. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon and having its discharge end located outside of the plane of the truck-wheels, and means for operating said platform, substantially as described.

2. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, a headboard at or near one end of said platform, and means for operating said platform, substantially as described.

3. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, supporting-rollers beneath said platform, and means for operating the platform, substantially as described.

4. In a grave-filler, the combination with a truck, of an extension-frame, means for adjusting said extension-frame, and a roller-platform mounted on the extension-frame, substantially as described.

5. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, and means for operating said platform consisting of a winding-shaft, and flexible connections between said winding-shaft and the roller-platform, substantially as described.

6. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, a stretching-cable connecting the opposite ends of said roller-platform, and means for operating said platform, substantially as described.

7. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, a stretching cable or chain connecting the opposite ends of the platform, rollers around which the platform travels, and platform-operating means consisting of a winding-shaft, and flexible connections interposed between said shaft and the platform, substantially as described.

8. In a grave-filler, the combination with a truck, of a slatted and flexible roller-platform mounted thereon, means for operating said platform, supporting-rollers located beneath the platform, and a covering-sheet for said platform, substantially as described.

9. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, means for operating said platform, and side-boards between which the platform operates, substantially as described.

10. In a grave-filler, the combination with a truck, of a roller-platform mounted thereon, means for operating said platform, extension side-boards between which the platform is located, and yoke-braces detachably associated with said extension-boards, substantially as described.

11. In a grave-filler, the combination with a truck, of antifriction-rollers journaled therein, an extension-frame supported on said rollers, and means for adjusting the extension-frame, substantially as described.

12. In a grave-filler, the combination with a truck, of antifriction-rollers journaled therein, an extension-frame supported on said rollers, means for adjusting said extension-frame, antifriction-rollers journaled in the extension-frame, a roller-platform supported on the last-named rollers, and means for operating said platform, substantially as described.

707,504. FASTENER. WILLIAM B. H. DOWER, Newton, Mass., assignor to Consolidated Fastener Company, Portland, Me. Filed June 7, 1902. Serial No. 110,572. (No model.)

Claim.—1. A stud member of a snap-fastener consisting of a ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the depending flange lying within the ring, and separated therefrom by the material to which the stud member is attached, the edge of the flange being turned outward so that the ring is held between the outward-turned edge of the flange and shoulder, substantially as shown and described.

2. A stud member of a snap-fastener consisting of a ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the flange lying within the ring and separated therefrom by an imperforate flexible material to which the stud member is attached, the flange being turned outward and the shoulder crushed downward, so as to bind the ring and confined material between the outwardly-turned edge of the flange and the shoulder, substantially as shown and described.

3. A snap-fastener consisting of a stud member and a socket member adapted to mutual engagement, the stud member consisting of a ring, a hollow stud having a central crown a neck below the crown, a shoulder and depending flange, the depending flange lying within the ring, and separated therefrom by the material to which the stud member is attached, the edge of the flange being turned outward so that the ring is held between the outward-turned edge of the flange and shoulder, and the socket member consisting of a cup, a stud-engaging collar lying within the cup, and separated therefrom by the material to which the socket member is attached, the edge of the cup being turned under the edge of the collar, and the material confined thereby, substantially as shown and described.

4. A stud member of a snap-fastener consisting of a tubular ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the depending flange lying within the ring, and separated therefrom by the material to which the stud member is attached, the edge of the flange being turned outward so that the ring is held between the outward-turned edge of the flange and shoulder, substantially as shown and described.

5. A stud member of a snap-fastener consisting of a split tubular ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the depending flange lying within the ring, and separated therefrom by the material to which the stud member is attached, the edge of the flange being turned outward so that the ring is held between the outward-turned edge of the flange and shoulder, substantially as shown and described.

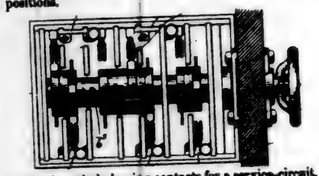
6. A stud member of a snap-fastener consisting of a tubular ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the flange lying within the ring and separated therefrom by an imperforate flexible material to which the stud member is attached, the flange being turned outward, and the shoulder crushed downward, so as to bind the ring and confined material between the outwardly-turned edge of the flange and the shoulder, substantially as shown and described.

7. A stud member of a snap-fastener consisting of a split tubular ring, a hollow stud having a central crown, a neck below the crown, a shoulder and depending flange, the flange lying within the ring and separated therefrom by an imperforate flexible material to which the stud member is attached, the flange being turned outward, and the shoulder crushed downward, so as to bind the ring and confined material between the outwardly-turned edge of the flange and the shoulder, substantially as shown and described.

707,505. ELECTRICAL SWITCH. LEONARD L. BLOCH, Boston, Mass., assignor of one-half to Sears B. Condit, Jr., Somerville, Mass. Filed Apr. 15, 1901. Serial No. 55,945. (No model.)

Claim.—1. In an electric switch, contacts for a line-circuit, independent contacts for a polyphase system, a single rotary hand-lever, and means for transferring the line-circuit by a single straight-ahead movement of the hand-lever from any one phase of the polyphase system to any other thereof.

2. An electric switch, having a plurality of contact-makers in a successive series for transferring a circuit from one source of supply to another, and a series of contacts coöperating therewith, said contact-makers being movable in an unvarying path only, into successive contact with said series of contacts, said switch having a break position between every two make positions.



3. An electric switch, having contacts for a service-circuit, and other contacts for a plurality of interrelated supply-conductors, a single hand-lever, and means for transferring by a single simple and unchangeable movement of the hand-lever said service-circuit from any two of said supply-conductors to any other two thereof.

4. An electric switch, having a rotatable shaft, provided with a series of contact-makers connected in pairs out of longitudinal alinement, coöperating contacts arranged in different circumferential positions to be simultaneously engaged by the contact-makers of a given pair and to be successively engaged by the contact-makers of successive pairs, as the shaft is rotated, and means for rotating said shaft.

5. An electrical apparatus, comprising a rotatable shaft, contact-makers carried thereby and connected by conductive material in pairs out of circumferential alinement with each other, contacts in position to be simultaneously engaged by the respective contact-makers of a given pair, and operating means for rotating said shaft.

6. An electrical apparatus, comprising a rotatable shaft, contact-makers adjustably carried thereby out of circumferential alinement with each other and connected in pairs by conductive material, contacts in position to be simultaneously engaged by the respective contact-makers of a given pair, and operating means for rotating the shaft.

7. An electrical apparatus, comprising a rotatable shaft, contact-makers carried thereon by rings adjustably mounted on the shaft, said contact-makers being out of circumferential alinement with each other and connected in pairs by conductive material, contacts in position to be simultaneously engaged by the respective contact-makers of a given pair, and means for rotating the shaft.

8. An apparatus containing make-and-break devices, including a rotatable shaft having contact-makers, and contacts mounted in position to be engaged by said contact-makers, one set of contacts being connected to the terminals of a service-circuit, and another set of contacts being connected to interrelated supply-conductors, as, for example, the wires from a polyphase generator, each of said service-circuit terminals having separate connection to contacts in its set one less in number than the number of supply-conductors in the said opposite set of contacts with which it coöperates.

707,506. METHOD OF TREATING MIXED SULFID ORES. ERNESTO FERRARIS, Monteponi, Italy. Filed July 23, 1902. Serial No. 117,390. (No specimens.)

Claim.—1. The process of decomposing mixed sulfid ores by means of concentrated sulfuric acid without the aid of extraneous heat.

2. The process of decomposing mixed sulfid ores containing zinc, and the production therefrom of zinc sulfate soluble in water, by means of concentrated sulfuric acid without the aid of extraneous heat.

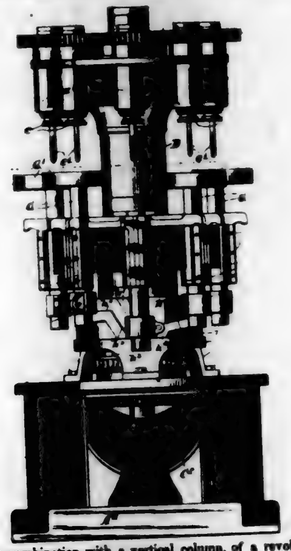
3. The process of decomposing mixed sulfid ores containing zinc, and the production therefrom of zinc sulfate soluble in water, by means of concentrated sulfuric acid, employed in the ratio of two molecules of the acid to each molecule of the metallic sulfids contained in the ore, without the aid of extraneous heat.

707,507. DRILLING-MACHINE. FREDERICK H. GARDNER, Beloit, Wis. Filed Nov. 5, 1901. Serial No. 81,566. (No model.)

Claim.—1. The combination with a vertical column, of a revolving work-table support, annularly arranged, rotative drill-spindles which revolve with said work-table support, work-tables located severally beneath said drill-spindles and provided with stems which have sliding, non-rotative engagement with said work-table support, a concentric stationary cam-ring below said work-table support provided on its cylindric surface with an upwardly-facing cam-shoulder, laterally-directed bearing-rollers on the lower ends of said stems which have bearing on said cam-shoulder, and means for vertically adjusting said bearing-rollers on said stems.

2. The combination with a vertical column, of a revolving work-table support, annularly arranged, rotative drill-spindles which revolve

with the work-table support, work-tables located severally beneath said drill-spindles and provided with stems which have sliding, non-rotative engagement with said work-table support, a stationary concentric cam-ring below said work-table support and provided on its cylindric surface with an upwardly-facing cam-shoulder, laterally-directed bearing-rollers on the lower ends of said stems which have bearing on said cam-shoulder, means for vertically adjusting said bearing-rollers on said stems, and means on said stems for limiting the vertical adjustment of the bearing-rollers thereon.



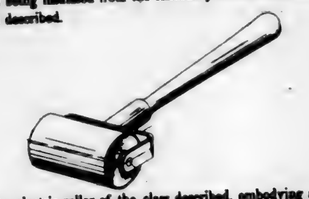
3. The combination with a vertical column, of a revolving work-table support, annularly arranged, rotative drill-spindles revolving with said work-table support, work-tables located severally beneath said drill-spindles and provided with stems which have sliding, non-rotative engagement with said work-table support, a concentric, stationary cam-ring below said work-table support and provided on its cylindric surface with an upwardly-facing cam-shoulder, laterally-directed bearing-rollers on said stems, laterally-directed bearing-rollers on said collars adapted for engagement with said cam-shoulder, said collars being provided with inwardly-projecting parts adapted to enter longitudinal grooves in said stems, and being capable of longitudinal movement with respect to the stems to permit vertical adjustment of the collars.

4. The combination with a vertical column, of a revolving work-table support, annularly arranged, rotative drill-spindles revolving with said work-table support, work-tables located severally beneath said drill-spindles and provided with stems which have sliding, non-rotative engagement with said work-table support, a concentric, stationary cam-ring below said work-table support and provided on its cylindric surface with an upwardly-facing cam-shoulder, collars surrounding the lower ends of said stems, laterally-directed bearing-rollers on said collars adapted for engagement with said cam-shoulder, said collars being provided with inwardly-projecting parts adapted to enter longitudinal grooves in said stems and being capable of longitudinal movement on the stems to permit vertical adjustment of the collars, and stops in said grooves adapted for engagement with the projecting parts of the collars to limit the vertical adjustment of the collars on said stems.

707,508. ELECTRIC ROLLER FOR MASSAGE AND THERAPEUTICAL PURPOSES. JOHN W. GIBBS, New York, N. Y. Filed Apr. 17, 1899. Serial No. 713,243. (No model.)

Claim.—1. An electric roller of the class described, embodying a stationary armature attached to a stationary shaft, and a revolvable magnetic field surrounding the same and carried within and by a revolvable metallic cylinder comprising the roller proper, and a holder forming an operating-handle and electrically connected to said stationary armature-shaft, said cylinder having insulated bearings upon said shaft, substantially as shown and described.

2. An electric roller of the class described, embodying a stationary armature in electrical connection with an operating-handle, and a revolvable magnetic field inclosed within and carried by a revolvable metallic cylinder surrounding said armature, said cylinder comprising the roller proper and being insulated from the stationary armature, substantially as shown and described.



3. An electric roller of the class described, embodying a revolvable metallic cylinder comprising the roller proper, a field-magnet carried by and contained therein, a stationary armature within said field-magnet, a metallic handle in electrical connection with the said armature, and insulated bearings for said cylinder, substantially as shown and described.

4. As a therapeutical appliance, the combination of a stationary armature attached to a stationary shaft and in electrical connection therewith, a metallic handle in electrical connection with said shaft, a revolvable magnetic field surrounding said armature, a revolvable metallic cylinder forming the roller proper and inclosing the said magnetic field and in electrical connection therewith, insulated collars upon and carrying said stationary shaft, and bearings carried by said cylinder and operating upon said collars, substantially as shown and described.

5. In a device for applying electricity superficially, the combination of a mechanical generator of electricity and a roller for contact with the body, the construction being such that the motion of the roller causes the operation of the generator of electricity.

6. In a device for the therapeutic application of electricity, the combination of a hollow roller-shell, said means for generating a current of electricity within said roller-shell, and also means for electrically connecting the said electricity-generator with the shell.

7. In a device for the therapeutic application of electricity, the combination of a roller, and means for generating electricity mechanically said electricity-generating means being constructed and arranged to be operated by the motion of the roller, and means for electrically connecting the said electricity-generator with the roller.

8. In a device for the therapeutic application of electricity, the combination of a hollow roller-shell, and means for generating a current of electricity within said roller-shell contained within said shell, and also means for electrically connecting said electricity-generator with the shell.

9. In a device for the therapeutic application of electricity, the combination of a roller, and means for generating a series of induced currents of electricity mechanically, contained within said roller, said electricity-generating means being constructed and arranged to be operated by the motion of the roller and means for electrically connecting the electric generator with the roller.

10. In a device for the therapeutic application of electricity, the combination with a movable roller-shell, of a relatively stationary part forming one member of the electricity-generating system, of another member of the generator of electricity secured to said shell, to cause the operation of the generator of electricity by the motion of the shell and means for electrically connecting the said generator with the shell.

11. In a device for the therapeutic application of electricity, a roller, a coil of wire contained within the same, and means to set up in said coil an induced current of electricity by the motion of the roller and means for electrically connecting the coil with the roller.

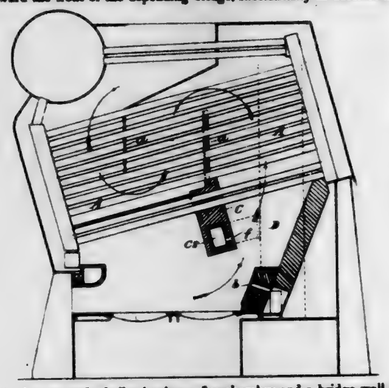
12. In a device for the therapeutic application of electricity, the combination of a roller, a coil of wire located adjacent to the roller, means to set up a series of induced currents of electricity in said coil by the motion of the roller and means for electrically connecting the said coil with the roller.

13. In a device for the therapeutic application of electricity, a roller, and a coil of wire, and means to set up in said coil an induced current of electricity by the motion of the roller contained in said roller.

707,509. BOILER AND ITS FURNACE. SAMUEL A. GRAHAM Sheffield, England, assignor of one-half to John Brown and Company Limited, Sheffield, England. Filed Apr. 10, 1902. Serial No. 102,604. (No model.)

Claim.—1. A water-tube boiler having a fire-chamber and a bridge-wall at the rear and extending upwardly from the bottom thereof, a combustion-chamber for the gases in the rear of the fire-chamber, water-tubes above both chambers, a depending bridge from the tubes between the two chambers, the said depending bridge and the bridge-wall forming a contracted passage between the two chambers, and means for directing air from the lower part of the bridge-wall across the contracted passage and toward the front of the depending bridge, substantially as described.

2. A water-tube boiler having a fire-chamber and a bridge-wall at the rear and extending upwardly from the bottom thereof, a combustion-chamber for the gases in the rear of the fire-chamber, water-tubes above both chambers, a hollow depending bridge from the tubes between the two chambers, the said depending bridge and the bridge-wall forming a contracted passage between the two chambers, and means for directing air from the lower part of the bridge-wall across the contracted passage and toward the front of the depending bridge, substantially as described.



3. A water-tube boiler having a fire-chamber and a bridge-wall at the rear and extending upwardly from the bottom thereof, a combustion-chamber for the gases in the rear of the fire-chamber, water-tubes above both chambers, a depending hollow bridge from the tubes between the two chambers and having openings into the rear combustion-chamber for directing air therefrom, the said bridge-wall and depending bridge forming a contracted passage between the two chambers and the bridge-wall having air-inlet openings near the bottom for directing air across said passage and toward the front of the depending bridge, substantially as described.

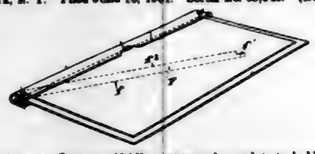
4. A water-tube boiler having a fire-chamber and a combustion-chamber in the rear of the same, water-tubes above said chamber and extending beyond it, a bridge-wall extending from one end of the fire-chamber to the extending ends of said tubes, a depending bridge from the water-tubes forming with the bridge-wall a contracted passage between the two chambers, and air-inlets near the bottom of the bridge-wall for directing air across said contracted passage and toward the front of the depending bridge, substantially as described.

5. A water-tube boiler having a fire-chamber and a combustion-chamber in the rear of the same, water-tubes above said chamber and extending beyond it, a bridge-wall extending from one end of the fire-chamber to the extending ends of said tubes, a depending bridge from the water-tubes forming with the bridge-wall a contracted passage between the two chambers, means for directing air through said depending bridge into the combustion-chamber, and air-inlets near the bottom of the bridge-wall for directing air across said contracted passage and toward the front of the depending bridge, substantially as described.

707,510. LIQUID-FUEL BURNER. ROBERT HALLET, Chicago, Ill., assignor of one-fourth to the Piano Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Original application filed Aug. 2, 1901, Serial No. 70,583. Divided and this application filed Nov. 5, 1901. Serial No. 81,231. (No model.)

Claim.—In a device of the class described, the combination with the stationary burner consisting of the shell adapted to be connected to the air-passage and having the circular recess 31 therein, the burner-tube connected to the oil-supply, of the block 36 having a passage therethrough and the circular portion 30 fitting into the recess 31 and adapted to rotate therein.

707,511. MANIFOLDING-TABLET. BENJAMIN F. HOARD, New York, N. Y. Filed June 18, 1901. Serial No. 65,046. (No model.)



Claim.—1. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a clamping device secured thereto, means to hold said clamping device in a rocking relation so as to move away from the front face of the base to insert the sheets thereunder, and with means to lock the clamp, sheets and base-plate immovably together along or near the edge of said base.

2. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a clamping device secured thereto, means to hold said clamping device in a rocking relation, so as to move away from the front face of the base to insert the sheets thereunder, and with means pivoted to the base-plate to lock the clamp, sheets and base-plate immovably together along or near the edge of said base.

3. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a clamping device secured thereto, means to hold said clamping device in a rocking relation, so as to move away from the front face of the base to insert the sheets thereunder, and with means whereby the said clamp may grasp the sheets along or near the edge of said base consisting of a locking-piece to engage the clamp on the rear face of the base.

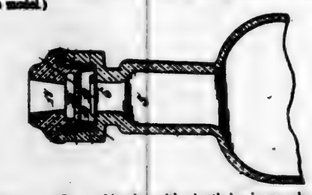
4. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a rocking U-shaped clamping device secured thereto, means to hold the clamp in a rocking relation so as to move from the front face of the base to insert the sheets thereunder, and with means to engage the clamp and front face of said plate along or near the edge of said base, consisting of a locking-bar to engage the clamping device on the rear face of the base.

5. In a manifolding-tablet, a base-plate to hold the sheets, provided with orifices, in combination with a rocking U-shaped clamping device secured thereto and provided with holding pins or rivets to work loosely in said orifices, and with means to engage the said clamp along or near the edge of the base, consisting of a locking-bar to engage the clamping device on the rear face of the base.

6. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a U-shaped clamping device inclosing the edge thereof, means to hold said clamping device in a rocking relation so as to move away from the front face of the base to insert the sheets thereunder, and with manually-actuated means to coact with the clamping device so as to hold the same together with the sheets tightly against the said plate or to allow it to rock thereon at will.

7. In a manifolding-tablet, a base-plate to hold the sheets, in combination with a clamping device secured thereto, means to hold said clamping device in a rocking relation so as to move away from the front face of the base to insert the sheets thereunder at one edge of said plate, and with manually-actuated means to operate the clamping device so as to hold the same together with the sheets tightly against the said plate or to allow it to rock thereon, at will, consisting of a pivoted locking-piece constructed and arranged to clamp the parts when it is parallel with the clamping device and to release the same when it is at an angle thereto.

707,512. NON-REFILLABLE BOTTLE. EDWARD HORRIGAN, Baltimore, Md., assignor of two-thirds to Thomas A. Bryan and Charles H. Boone, Baltimore, Md. Filed June 11, 1901. Serial No. 64,138. (No model.)



Claim.—1. In combination with a bottle having a valve-seat formed in its neck, a spring-controlled flap-valve located on said seat and provided with a weight, so that when the valve is moved from its seat against the resistance of the spring by the weight of the liquid it will remain open during the time the neck portion of the bottle is turned downward beyond the horizontal and the liquid is being poured therefrom, but will close in all other positions of the bottle, and an apertured plug secured in said neck and adapted to hold the valve in place and prevent access thereto.

2. In combination with a bottle having its neck provided with a valve-seat, a valve on said seat comprising a valve member 6 of metal having a spring member, a weight on said valve whereby when the valve is moved from its seat against the resistance of its spring by the weight of the liquid it will remain open during the time the neck portion of the bottle is turned downward beyond the horizontal and the liquid is being poured therefrom, but will close in all other positions of the bottle, and a plug secured in said neck above said valve and having a circuitous passage therein.

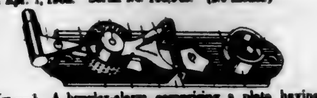
3. In combination with a bottle having its neck provided with a valve-seat, a valve on said seat comprising a valve member 6 of metal having an integral spring member, a weight on said valve, whereby when the valve is moved from its seat against the resistance of its spring by the weight of the liquid it will remain open during the time the neck portion of the bottle is turned downward beyond the horizontal and the liquid is being poured therefrom, but will close in all other positions of the bottle, and a plug secured in said neck above said valve and having a circuitous passage therein.

4. In combination with a bottle having its neck provided with a valve-seat, a valve on said seat comprising a valve member 6 of metal having a spring tending normally to close the valve, a weight on said valve whereby when the valve is moved from its seat against the resistance of the spring by the weight of the liquid it will remain open during the time the neck portion of the bottle is turned downwardly beyond the horizontal and the liquid is being poured therefrom, said spring having power sufficient to close the valve against the resistance of the weight when the valve is in an upright position, and a plug secured in said neck above said valve and have a circuitous passage therein.

5. In combination with a bottle having its neck provided with a valve-seat, a valve on said seat comprising a flat valve member of metal having an integral spring-arm provided with an upward extension, an apertured plug secured in said neck above said valve and separate therefrom, said plug having a portion bearing on said spring-arm and clamping said upward extension between itself and the wall of the neck.

6. In combination with a bottle having a valve-seat in its neck, a flap-valve located on said seat, and a plug secured in said neck and having a portion of each side cut away, said plug having a longitudinal opening or mouth extending part way through the plug, a passage extending at right angles to said opening from side to side of the plug and communicating with said opening and a space or recess provided in its bottom to permit movement of the valve.

707,513. BURGLAR-ALARM. JAMES H. HOWARD, Kansas City, Kans., assignor of one-third to H. Gordon Harris, Kansas City, Kans. Filed Apr. 1, 1902. Serial No. 100,963. (No model.)



Claim.—1. A burglar-alarm, comprising a plate, having a socket near one end, a hammer pivoted to said plate, and provided with a head to enter said socket, a spring for operating said hammer and causing said head to enter said socket, and a foraminous cap carried by the hammer and concentrically surrounding its head and adapted to cover and envelop the socket when the hammer-head is engaged therewith.

2. A burglar-alarm, comprising a plate, having a socket near one end, a hammer pivoted to said plate, and provided with a head to enter said socket, a spring for operating said hammer and causing said head to enter said socket, a foraminous cap carried by the hammer and concentrically surrounding its head and adapted to cover and envelop the socket when the hammer-head is engaged therewith, and a trigger mechanism, normally overlapping and holding the hammer cocked.

3. A burglar-alarm, comprising a plate having a notched socket at one end, a hammer pivoted to said plate and adapted to extend through said notches, and provided with a head to enter said socket between said notches, a foraminous cap secured to the hammer concentrically of its head and provided with an opening through which one end of the hammer projects and a notch through which the hammer at the opposite side of the head extends; said foraminous cap being adapted to envelop the socket when the hammer occupies the latter, a spring for operating the hammer, and a trigger holding the hammer normally cocked.

4. A burglar-alarm, comprising a plate, having a socket near one end, a hammer pivoted to said plate, and provided with a head to enter said socket, a spring for operating said hammer and causing said head to enter said socket, a foraminous cap carried by the hammer and concentrically surrounding its head and adapted to cover and envelop the socket when the hammer-head is engaged therewith, and a trigger pivoted to the plate and normally holding the hammer cocked, and provided with a compressible friction-block.

5. A burglar-alarm, comprising a plate, having a socket near one end, a hammer pivoted to said plate, and provided with a head to enter said socket, a spring for operating said hammer and causing said head to enter said socket, a standard movable with one of the window-sashes, and a rod pivoted to operate vertically upon said standard, and provided at one end with a friction-shoe engaging the other sash, and at its opposite end with a sliding plate for overlapping and holding the trigger cocked.

707,514. HANDLE-BAR SUPPORT. LAZARUS S. KALLAJIAN, Boston, Mass. Filed June 28, 1901. Serial No. 66,322. (No model.)

Claim.—1. In a bicycle, a reversible handle-bar post, both ends of which are adapted to be inserted in the steering-head, an expander on the interior of said steering-head and adapted to coöperate with that end of the handle-bar post inserted into the said head, means to operate said expander from the exterior of the steering-head, and means to secure the handle-bar to the projecting end of the said handle-bar post.

2. In a bicycle, a rigid one-piece handle-bar post of substantially L shape, both arms of which are constructed to be capable of insertion in the steering-head of the bicycle, an expanding device on the interior of said steering-head and adapted to coöperate with the end of that arm of the handle-bar post which is inserted in the steering-head to clamp said handle-bar post in position, and a reversible bar-holder secured to the projecting arm of the handle-bar post, said handle-bar holder having an elongated stem to the end of which the handle-bars are secured.

3. In a bicycle, a substantially L-shaped handle-bar post, both arms of which are constructed so as to be capable of insertion in the steering-head, an expander on the interior of the steering-head adapted to receive the end of that arm of the handle-bar post which is inserted in the said steering-head, means extending through the said arm of the handle-bar post to render said expander operative to clamp the handle-bar post in position, combined with a bar-holder secured to the projecting end of the said handle-bar post.

4. In a bicycle, a rigid, substantially L-shaped handle-bar post, both arms of which are constructed to be capable of insertion into the steering-head of the bicycle, an expander on the interior of said steering-head, adapted to coöperate with that arm of the handle-bar post which is inserted in said head, and means accessible from the exterior of said head to operate the expander, combined with a reversible handle-bar holder detachably connected to the projecting end of the handle-bar post.

5. In a bicycle, a substantially L-shaped handle-bar post, both arms of which have conical ends and are constructed to be capable of insertion into the steering-head of the bicycle, an expander on the interior of said head, constructed to receive the conical end of that arm of the handle-

bar post inserted into the head, said expander operating to clamp the handle-bar post in position, means accessible from the exterior of said head to operate the expander, and a handle-bar holder adapted to be secured to the conical end of the projecting arm of said handle-bar post.

6. In a bicycle, a rigid one-piece handle-bar post of substantially L shape, both arms of which are constructed to be capable of insertion in the steering-head, an expanding device on the interior of the said steering-head and adapted to coöperate with the end of that arm of the handle-bar post which is inserted in the steering-head to clamp said handle-bar post in position, means to operate the said expander from the exterior of the steering-head, and a reversible bar-holder secured to the projecting arm of the handle-bar post.

7. In a bicycle, a substantially L-shaped handle-bar post, both arms of which are constructed to be inserted in the steering-head of a bicycle, means on the interior of said steering-head to coöperate with either arm of the handle-bar post and clamp the same in the said steering-head, said means being operable from the exterior of the head, a bar-holder having an elongated stem to the end of which the handle-bars are secured, and means whereby the bar-holder may be detachably secured to the projecting end of the handle-bar post with the stem of the said bar-holder either depending from the projecting end of the handle-bar post or extending upwardly therefrom.

8. In a bicycle, a substantially L-shaped handle-bar post, each arm thereof having a conical end portion and adapted to be inserted in the steering-head of the bicycle, an expander adapted to engage that arm which is in the head, and a bar-holder having a conical eye to receive the end of the other arm.

9. In a bicycle, a substantially L-shaped handle-bar post having arms of different length, each arm having a conical end portion and adapted to be inserted in the steering-head of the bicycle, an expander adapted to engage that arm which is in the head, and a bar-holder having a conical eye to receive the end of the other arm.

10. In a bicycle, a reversible handle-bar post having both ends thereof substantially conical in shape, an expander having an exterior shaped to fit the interior of the steering-head of a bicycle, said expander having a conical bore adapted to receive either end of the handle-bar post, and an adjusting-bolt passing longitudinally through the handle-bar post and having a screw-threaded engagement with the expander, combined with a bar-holder constructed to be secured to the projecting end of the handle-bar post.

707,515. PNEUMATIC HAMMER. HENRY J. KINMAN, Chicago, Ill., assignor to the Chicago Pneumatic Tool Company, Trenton, N. J., a Corporation of New Jersey. Filed June 24, 1901. Renewed July 19, 1902. Serial No. 116,243. (No model.)

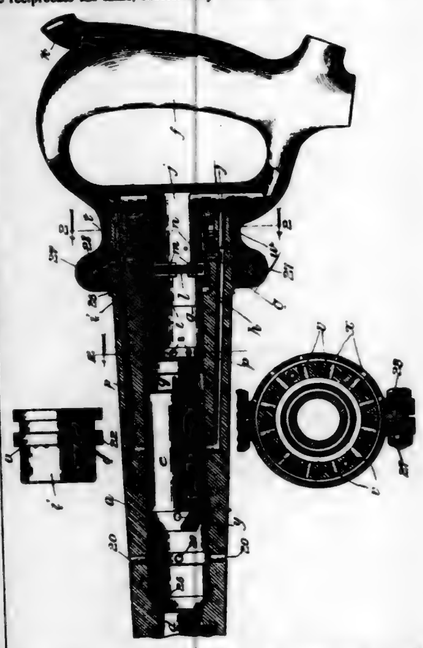
Claim.—1. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle-base provided with a cylindrical projection extending into the rear end of the cylinder to close the same and provide an annular valve-chamber between it and the cylinder, and a tubular controlling-valve reciprocatingly mounted in such valve-chamber to govern the admission of the motive fluid to the cylinder, substantially as described.

2. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same and provide an annular valve-chamber between it and the cylinder, and a tubular controlling-valve reciprocatingly mounted on such projection to govern the admission of motive fluid, substantially as described.

3. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same forming a continuation of the supply-channel and providing an annular chamber between it and the cylinder, a partition in such tubular projection providing a by-pass for admitting the motive fluid to the cylinder, and a tubular controlling-valve surrounding such projection and reciprocatingly mounted in the annular valve-chamber to admit the motive fluid to the cylinder, substantially as described.

4. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle provided with an integral tubular projection extending into the rear end of the cylinder to close the same form a continuation of the supply-channel and provide an annular valve-chamber between it and the cylinder and provided with perforations communicating with the continuous opening to furnish motive fluid for the front end of the cylinder, a transverse partition in such tubular projection forming in connection therewith a by-pass through which the motive fluid passes to the rear end of the cylinder, and a tubular controlling-valve surrounding such projection and reciprocatingly mounted in the valve-chamber to govern the admission of the motive fluid to the rear chamber of the cylinder, substantially as described.

5. In a tool of the class described, the combination of a cylinder provided with a reciprocating hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same and provide in connection therewith an annular valve-chamber, a tubular differential controlling-valve slidingly mounted in the annular valve-chamber to govern the admission of the motive fluid to the cylinder, means for admitting a constant supply of motive fluid to the smaller area of the tubular differential controlling-valve, and means arranged to be operated by the movements of the piston-hammer to intermittently admit motive fluid to the larger superficial area of the differential valve to reciprocate the same, substantially as described.



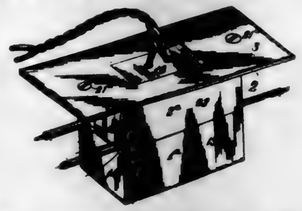
6. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same and form the connection with an annular valve-chamber, a shouldered tubular differential valve in such valve-chamber, a main supply-passage formed in the hammer-handle and extending into the axial tubular opening of the projection, by-passes in such tubular projection, a transverse partition arranged in such tubular projection to assist in forming such by-passes and admit motive fluid to the rear of the piston-hammer, constant-supply passages *n* in the tubular projections, constant-supply passages *o* in the tubular valve to furnish a constant supply of motive fluid to the smaller superficial area of the shoulder, a passage *r* in the walls of the cylinder connecting the operating-chamber with the valve-chamber to the rear of the face of the valve and arranged to be opened and closed by the movements of the piston-hammer to furnish an intermittent supply of motive fluid to the larger area of the differential valve and reciprocate the same, substantially as described.

7. In a tool of the class described, the combination of a cylinder provided with a reciprocating piston-hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same and form in connection therewith an annular valve-chamber, a tubular differential valve slidingly mounted in such valve-chamber, means for furnishing a constant supply of motive fluid to the smaller area of the differential valve, means arranged to be operated by the movements of the piston-hammer to furnish an intermittent supply of motive fluid to the larger area of the differential valve and reciprocate the same, an annular exhaust-channel *u* connecting with the open air, a second exhaust-channel *t* connected with passages through the cylinder with the rear end of the operating-chamber and arranged to be opened and closed by the movements of the reciprocating controlling-valve, substantially as described.

8. In a tool of the class described, the combination of a cylinder provided with a reciprocating hammer, a handle-base provided with a tubular projection extending into the rear end of the cylinder to close the same and form an annular valve-chamber in connection therewith, a tubular differential valve slidingly mounted in such valve-chamber, means furnishing a constant supply of motive fluid to operate such differential valve in one direction, means for furnishing an intermittent supply of motive fluid to the larger superficial area thereof to move it in the opposite direction, an exhaust-passage in the rear end of the cylinder arranged to be opened and closed by the movements of the differential valve, a supplementary valve-exhaust opening connected with the front end of the annular valve to release any air confined therein, and an emergency exhaust-passage in the walls of the cylinder connected with the front end of the operating-chamber and the exhaust-openings in the annular chamber to exhaust any air in the front end of such operating-chamber, substantially as described.

9. In a tool of the class described, the combination of a cylinder provided with a reciprocating hammer and a rear outer threaded portion, a handle-base provided with a central tubular projection extending into the rear end of the cylinder to close the same and provide an annular chamber between it and the walls of the cylinder, an outer annular tubular projection having an internal threaded bore engaging with the threads on the rear end of the cylinder, and bolt mechanism for locking the threaded tube of the handle-base in engagement with the threaded surface of the cylinder, substantially as described.

707,516. PLUG-RECEPTACLE. CHARLES J. KLEIN, New York N. Y., assignor to the C-K Manufacturing Company, New York, N. Y., and Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 5, 1902. Serial No. 101,474. (No model.)



Claim.—1. A plug-receptacle provided with a face-plate having a plug-opening therein; and closure means for said plug-opening embodying a pivoted, tensionally-actuated member arranged to be swung inwardly of the receptacle upon the insertion of the plug.

2. A plug-receptacle provided with a face-plate having a plug-opening therein; and closure means for said plug-opening comprising two oppositely-disposed, pivoted, tensionally-actuated members arranged to be swung oppositely and inwardly of the receptacle upon the insertion of the plug.

3. A plug-receptacle provided with a face-plate having a plug-opening therein; closure means for said plug-opening embodying a pivoted, tensionally-actuated member arranged to be swung inwardly of the receptacle upon the insertion of the plug; and means for maintaining said pivoted member normally flush with the outer surface of said face-plate.

4. A plug-receptacle provided with a face-plate having a plug-opening therein; closure means for said plug-opening comprising two oppositely-disposed, pivoted, tensionally-actuated members arranged to be swung oppositely and inwardly of the receptacle upon the insertion of the plug; and means for maintaining said pivoted members normally flush with the outer surface of said face-plate.

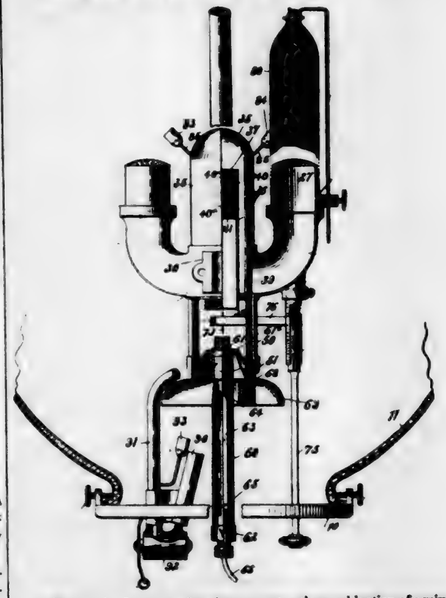
5. A plug-receptacle provided with a face-plate having a plug-opening therein; and closure means for said plug-opening opening inwardly of the receptacle and operated by the insertion of the plug.

6. A plug-receptacle provided with a face-plate having a plug-opening therein; closure means for said plug-opening comprising two tensionally-actuated members which are pivoted to said face-plate at opposite sides of said plug-opening and are arranged to be swung oppositely and inwardly of the receptacle upon the insertion of the plug; and means for maintaining said tensionally-actuated members normally flush with the outer surface of said face-plate.

7. An improved plug-receptacle, comprising an inner body member and an outer body member jointly forming an inner receptacle-chamber; receptacle-contacts arranged within said receptacle-chamber; a face-plate covering said outer body member and having a plug-opening formed therein; closure means for said plug-opening comprising two spring-projected, pivoted members connected with said face-plate and arranged to be swung oppositely and inwardly of the receptacle upon the insertion of the plug; and means for maintaining said spring-projected members normally flush with the outer surface of said face-plate; said inner body member and said outer body member being grooved in registration to receive line-wires in position for connection with said receptacle-contacts.

8. In an improved plug-receptacle, an inner body member and an outer body member jointly forming an inner receptacle-chamber; receptacle-contacts arranged within said receptacle-chamber; grooves formed in registration in said inner body member and said outer body member and adapted to receive the line-wires in connection with said receptacle-contacts; and means for securing the said body members in operative connection.

707,517. HYDROCARBON-VAPOR-BURNING APPARATUS. AUGUS. B. MACKLIN, Brooklyn, N. Y. Filed Dec. 11, 1900. Renewed June 13, 1902. Serial No. 111,577. (No model.)



Claim.—1. In a vapor-burning apparatus, the combination of a mixing-chamber having an inlet for vapor and air, a burner communicating with the mixing-chamber, and a vaporizer having a fuel-supply and a vapor-discharge nozzle arranged adjacent to and separated from the mixing-chamber with a free air-space between the mixing-chamber and vaporizer, with a movably-mounted nozzle-clearing needling device located exteriorly to the vaporizer and mixing-chamber, said nozzle-clearing device carrying a needle which is normally supported away from the vapor-nozzle in the air-space outside the zone of great heat and is adapted to be moved into the free air-space between the mixing-chamber and vaporizer in operative relation to the vapor-nozzle, substantially as set forth.

2. In a vapor-burning apparatus, the combination of the vertically-arranged mixing-chamber and vaporizer having a free space between them, the former having an inlet for air and vapor and the latter a fuel-supply and a vapor-discharge nozzle, and a vapor-burner communicating with the mixing-chamber, with a nozzle-clearing needle operating in the free space between the mixing-chamber and vaporizer, and a movable support for said needle, mounted upon the exterior of the apparatus, whereby the needle may be moved into and out of operative relation with the nozzle, and be supported normally outside the zone of greatest heat, substantially as set forth.

3. In a vapor-burning apparatus, the combination of a mixing-chamber, a vapor-burner communicating therewith, and a vaporizer having a fuel-supply and a vapor-discharge nozzle, with a nozzle-cleaning needle, and a horizontally-rotatable and vertically-movable support carrying the nozzle-needle, said needle-support being mounted upon the exterior of the apparatus at a point removed from the zone of greatest heat, substantially as set forth.

4. In a vapor-burning apparatus, the combination of a mixing-chamber, a vapor-burner communicating therewith, and a vaporizer having a fuel-supply and a vapor-discharge nozzle, with a nozzle-needle, a rod or bar having an arm extending from it in which the needle is mounted, a support for said rod or bar, a horizontally-and vertically extending guide

groove or slot on one of said parts and a projection on the other engaging said guide groove or slot, whereby the rod or bar may be rotated and moved vertically upon its support, substantially as and for the purpose set forth.

5. In a vapor-burning apparatus, the combination of a mixing-chamber, a vapor-burner communicating therewith, and a vaporizer having a fuel-supply and a vapor-discharge nozzle, with a nozzle-needle, a tubular support having a vertically and horizontally extending guide groove or slot, a rod or bar mounted in said tubular support, and an arm extending from said rod or bar through said guide groove or slot and supporting the needle, substantially as and for the purpose set forth.

6. In a vapor-burning apparatus, the combination of a mixing-chamber, a vapor-burner communicating therewith, a vaporizer having a fuel-supply and a vapor-discharge nozzle, parts connecting the mixing-chamber and vaporizer, whereby one is supported by the other with a free space between them, with a nozzle-needle operating in the free space between the mixing-chamber and vaporizer, a vertically-movable rotatable supporting-piece mounted adjacent to one of the parts connecting the mixing-chamber and vaporizer, and a curved arm extending from said supporting-piece and carrying the needle and adapted to project around one of said connecting parts to present the needle in proper relation with the vapor-nozzle, substantially as set forth.

7. In a vapor-burning apparatus, the combination of a mixing-chamber, and a vapor-burner with a vertically-arranged vaporizer, having a fuel-inlet at its lower end, and a vapor-discharge nozzle at its upper end, an inner bell-shaped section arranged in the vaporizer between the fuel-inlet and vapor-discharge nozzle, to form a cushioning-chamber to equalize the flow of fuel into the vaporizer, substantially as and for the purpose set forth.

8. In a vapor-burning apparatus, the combination of a mixing-chamber, and a vapor-burner, with a vertically-arranged vaporizer comprising an outer tubular section and an inner bell-shaped section which is open at its lower end and closed at its upper end to form an equalizing cushioning-chamber, said inner bell-shaped section communicating adjacent to its open end with the outer tubular section of the vaporizer, a fuel-supply leading to the open end of the inner section, and a vapor-discharge nozzle arranged in the upper end of the outer section, substantially as set forth.

9. In a vapor-burning apparatus, the combination of a mixing-chamber, and a vapor-burner, with a vertically-arranged vaporizer comprising two tubular sections arranged one within the other and communicating at or near their lower ends, said inner section having a fuel-inlet at its lower end to form an air-cushioning chamber, a vapor-discharge nozzle leading from the upper end of the outer section, and means for applying heat to the outer section.

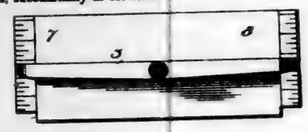
10. In a vapor-burning apparatus, the combination of a mixing-chamber, and a vapor-burner, with a vertical vaporizer comprising an outer tubular section, a vapor-discharge nozzle leading from the upper end of the outer section, an inner tubular section closed at its upper end and arranged concentrically within the outer section and having ports or openings adjacent to its base which communicate with the chamber of said outer section, a fuel-supply communicating with the base of the inner section, and an auxiliary vapor-burner supported adjacent to the vaporizer and having suitable vapor communication with the mixing-chamber, substantially as set forth.

11. In a vapor-burning apparatus, the combination of the vertically-arranged mixing-chamber and vaporizer having a free air-supply space between them, a vapor-burner communicating with the mixing-chamber, a fuel-supply and a vapor-discharge nozzle for the vaporizer, an auxiliary vapor-burner arranged beneath said free air-supply space adjacent to the vaporizer to heat the same, an exteriorly and movably mounted needling device operating in the free space between the mixing-chamber and vaporizer, and a shield surrounding the auxiliary burner to prevent the products of combustion from being drawn into the mixing-chamber by the vapor-current, substantially as set forth.

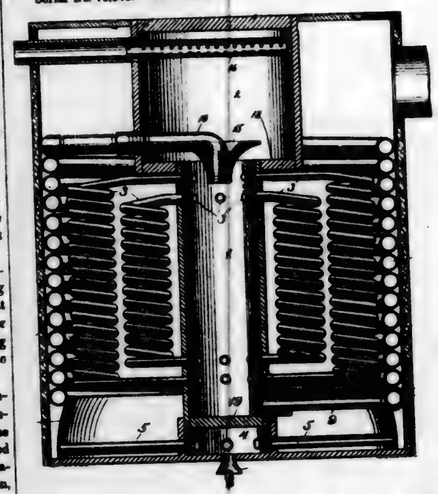
12. In a vapor-burning apparatus, the combination of the vertically-arranged mixing-chamber and vaporizer having a free air-supply space between them, a vapor-burner communicating with the mixing-chamber, a fuel-supply and a vapor-discharge nozzle for the vaporizer, an auxiliary vapor-burner surrounding the vaporizer beneath the said free air-supply space, tubes communicating between the mixing-chamber and said auxiliary burner, an exteriorly and movably mounted needling device operating in the free space between the mixing-chamber and vaporizer, and a shield surrounding said auxiliary burner to prevent the products of combustion being drawn into the mixing-chamber, substantially as set forth.

707,518. COMBINED PLUMB-BOB, LEVEL, &c. DAVID L. MCDERMOTT, Carlisle, Pa., assignor of one-half to J. A. Graham, Carlisle, Pa. Filed May 17, 1901. Serial No. 60,722. (No model.)

Claim.—As a new article of manufacture, a combined plumb-bob, level, &c., consisting of a rectangular piece or board having notched lower corner edges, and, ranging in substantially vertical alinement with said notched corner edges, indicia or graduations in inches &c., a centrally-pivoted straight-edge or bar, with its upper edge provided with a spirit-level, and near the end adapted to register or play over said indicia or graduations, said board or piece having upon its opposite surface a pivoted plumb pendulum or rod arranged to operate in the direction of the length of said board, with its normally upper end working in connection with a spirit-level, and a keeper for the retention of said plumb pendulum or rod, substantially as set forth.



707,519. BOILER. AUGUST W. OPELDT, Newark, N. J., assignor, by direct and mesne assignments, to Salamandrine Boiler Company, New York, N. Y., a Corporation of New York. Filed Sept. 28, 1901. Serial No. 76,975. (No model.)



Claim.—1. In a boiler, the combination with a steam and water chamber, of generating-tubes connected therewith, a coiled generating-tube surrounding said steam and water chamber and first-mentioned generating-tubes, and connected with said chamber, said coiled outer tube having closely-wound coils forming substantially a wall adapted to confine within itself the products of combustion and heated gases by which said generating-tubes are heated, and a combustion-chamber beneath the generating-tubes provided with an encircling flame-guard structurally separate from and independent of the generating-tubes of the boiler, extending substantially to the inner side of said outer coiled tube inclosing the entire space within which combustion takes place, and serving to prevent the passage of the products of combustion and heated gases to the outside of said coiled tube.

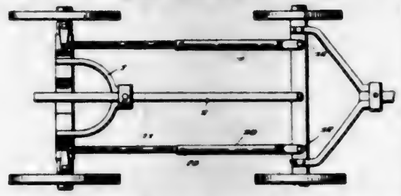
2. In a boiler, the combination with a steam and water chamber, of generating-tubes connected therewith, a coiled generating-tube surrounding said steam and water chamber and first-mentioned generating-tubes, and connected with said chamber, said coiled outer tube having closely-wound coils forming substantially a wall adapted to confine within itself the products of combustion and heated gases by which said generating-tubes are heated, said coil having a feed connection through which feed-water may be introduced, and a combustion-chamber beneath the generating-tubes provided with an encircling flame-guard structurally separate from and independent of the generating-tubes of the boiler, extending substantially to the inner side of said outer coiled tube inclosing the entire space within which combustion takes place, and serving to prevent the passage of the products of combustion and heated gases to the outside of said coiled tube.

3. In a boiler, the combination with a steam and water chamber,

of generating-tubes connected therewith, a generating-coil surrounding said steam and water chamber and generating-tubes, and connected with said chamber, the upper portion of said coil projecting into said chamber and bent downwardly, and a baffle-plate upon the end of said coil.

4. In a boiler, the combination, with a tubular steam and water chamber, closed at the top and bottom, and generating-tubes around the same and connected thereto, of a casing surrounding the generating-tubes, and a bottom plate having an annular flange whereby it is secured to said steam and water chamber, the space within said flange forming a distributing-chamber for a burner, and having burners connected thereto.

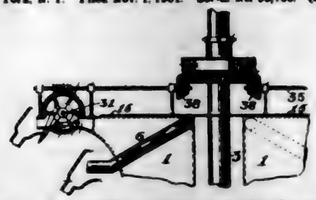
707,520. RUNNING-GEAR FOR WAGONS. FRANK H. PICKARD, Hill City, Tenn., assignor of one-half to Paul W. Trewhitt, Hill City, Tenn.; T. W. Stanfield administrator of said Frank H. Pickard, deceased. Filed Dec. 31, 1900. Serial No. 41,748. (No model.)



Claim.—1. In a device of the type set forth, the combination with the front and rear axles of a vehicle, of a pair of plates secured to the rear axles and extending beyond the ends thereof, a spindle carrying a vertical member comprising an enlarged portion received between said plates and rounded shanks extending through the plates, with squared shanks on the ends of the rounded shanks, levers connected to the squared shanks above and below the axle, and rods carrying a forked end movably secured to said levers, the other end of the rods being pivoted to the front axle, said rods being movable in parallel relation with each other.

2. In a device of the type set forth, the combination with the front and rear axles of a vehicle, of a spindle having a vertical member pivotally secured to each end of the rear axle, levers connected to the ends of the vertical member, and rods movable in parallel relation with each other pivoted to the front axle and carrying forked rear ends pivotally connected to said levers.

707,521. CENTRIFUGAL MACHINE. HARALD DE RAASLOFF, New York, N. Y. Filed Nov. 1, 1901. Serial No. 80,709. (No model.)



Claim.—1. In a centrifugal machine, the combination with a rotary separating-chamber provided with a discharge-outlet, of a continuously-operating rotary valve in the said discharge-outlet sealing the outlet and adapted to transfer separated material, substantially as described.

2. The combination in a centrifugal separator, of a nozzle for the discharge of separated material, a chambered rotary valve in said nozzle, and side and peripheral walls of said nozzle which make water-tight fit with the valve, said peripheral walls being of greater extent than the opening of the chamber in the valve, substantially as described.

3. The combination in a centrifugal separator, of a nozzle for the discharge of separated material, a valve in said nozzle having a plurality of chambers for said material, side and peripheral walls of said nozzle which make water-tight fit with said valve, and said peripheral walls being of greater area than the opening of any chamber of the valve, substantially as described.

4. In a centrifugal machine, the combination with a rotary separating-chamber provided with a discharge-outlet, of a continuously-operating rotary valve in said discharge-outlet, and independently-rotating means for operating said valve, substantially as described.

5. In a centrifugal machine, the combination with a rotary separating-chamber provided with a discharge-outlet, of a continuously-operating rotary valve in said outlet, and independently differentially speeded means for operating said valve, substantially as described.

6. In a centrifugal machine, the combination with a plurality of rotary separating-chambers symmetrically disposed around the axis of rotation of the said chambers, and provided with discharge-outlets, of a continuously-operating rotary valve in each outlet, and independently differentially speeded means for operating said valves, substantially as described.

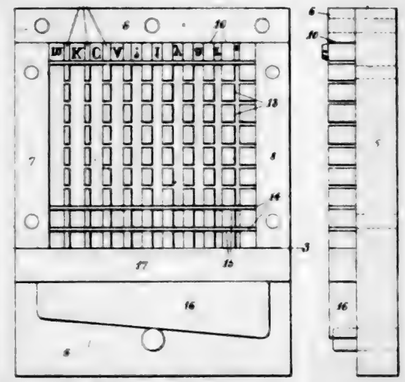
7. In a centrifugal machine, the combination with a rotary separating-chamber provided with a discharge-outlet, of a continuously-operating valve in said discharge-outlet sealing the same and adapted to transfer separated material, and an independently differentially speeded gear revolving around the center of rotation of said separating-chamber and operatively connected with said valve to rotate the same, substantially as described.

8. In a centrifugal machine, the combination with a rotary separating-chamber provided with a discharge-outlet, of a continuously-operating rotary valve in said discharge-outlet sealing the same and adapted to transfer separated material, independently-speeded means rotating around the axis of rotation of said chamber for actuating said valve, and devices for varying the speed of said means, substantially as described.

9. In a centrifugal machine, the combination with a plurality of rotary separating-chambers symmetrically disposed around the axis of rotation of the chambers and provided with discharge-outlets, of a continuously-operating rotary valve in each outlet sealing said outlet and adapted to transfer separated material, independently-speeded means rotating around said axis for operating said valves, and devices for varying the speed of said means, substantially as described.

10. The combination in a centrifugal separator, of a plurality of nozzles for the discharge of separated materials, a valve having a plurality of chambers for separated material in each nozzle, a gear adapted to rotate around the center of rotation of the separator, means to vary the velocity of said gear, a worm actuated by said gear, and a worm-wheel on each valve meshing with said worm, substantially as described.

707,522. TYPE-CHASE FOR MAKING MATRIX-PLATES. JOHN R. REYNOLDS, Hartford, Conn., assignor, by mesne assignments, to Goodson Graphotype Company, a Corporation of New Jersey. Filed Dec. 5, 1901. Serial No. 84,778. (No model.)



Claim.—1. A chase or form for type, consisting of a base, a series of projecting independent abutments integral with the base for locating the type in lines and columns, and means for locking the type against the abutments.

2. A chase or form for type, consisting of a base, a series of projecting abutments integral with the base, of a width substantially equaling the pointwise dimensions of the type, and means for locking the type against the abutments.

3. A chase or form for type, consisting of a base, a series of projecting abutments integral with the base, of a width substantially equaling the pointwise dimensions of the type, and of varying thicknesses inversely proportioned to the setwise dimensions of the respective type, and means for locking the type against the abutments.

4. A form or chase for the purpose specified, provided with fixed partitions for locating the respective pieces of type in predetermined setwise relation and alinement, in accordance with a standard index-plate.

5. A form or chase for the purpose specified, provided with a series of fixed partitions for independently locating the respective pieces of type in alined vertical columns and setwise spacing, in accordance with a standard index-plate.

6. A type-chase, provided with a series of fixed partitions for inde-

pendently locating the pieces of type in alined vertical columns, and in alined horizontal lines, spaced in accordance with a standard index-plate, and means for locking the type against the partitions.

7. A type-chase provided with a series of fixed partitions for independently spacing the individual type in straight lines and alined columns, rules located between the partitions, for spacing and alining the type thereof in lateral lines at right angles with the columns, and means for locking the type against the partitions.

8. A type-chase, provided with a series of fixed partitions forming compartments for independently locating the separate pieces of type in alined vertical columns, the partitions being interrupted by transverse seats for rules, for alining and separating the lines, and means for locking the type against the partitions.

9. A type-chase, provided with a series of partitions substantially equaling in width the pointwise dimensions of the type-bodies, separated by a series of transverse seats for rules, for separating and alining the lines.

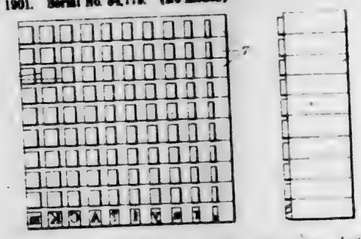
10. A type-chase, provided with a series of partitions of a width substantially equaling the pointwise dimensions of the type-bodies, and of a thickness substantially equaling the desired linear spacing of the type, less the respective thicknesses of those type.

11. A type-chase, provided with a series of separate partitions arranged in columns, separated by transversely-disposed rules, the thickness of the partitions in the respective columns increasing from one side to the other of the chase, in accordance with the decreasing thicknesses of the type to be held therein.

12. A type-chase, provided with a series of fixed partitions separated by transversely-disposed rules forming separate compartments for independently locating the respective pieces of type in alined vertical columns and lines, and means for locking the type against the partitions.

13. A type-chase, provided with a series of column-partitions separated by a series of transversely-disposed line-rules forming separate compartments for the respective pieces of type, the compartments for the succeeding columns being arranged in the order of their decreasing width.

707,528. MASTER TYPE-BAR FOR MATRIX-PLATES. JOHN R. REYNOLDS, Hartford, Conn., assignor, by mesne assignments, to Goodson Graphotype Company, a Corporation of New Jersey. Filed Dec. 5, 1901. Serial No. 84,779. (No model.)



Claim.—1. A master-type-bar blank provided with projections for the characters spaced and alined in accordance with the predetermined positions of those characters.

2. A master-type-bar blank provided with projections spaced and alined in accordance with the predetermined positions of the desired letters, the width of the said projections transversely of the bar being substantially in accordance with the pointwise dimensions of the desired type-bodies.

3. A blank for a line of master-type, having a thickness equaling the desired pointwise spacing of the lines provided with projections of a width substantially equaling the required pointwise dimensions of the master-type.

4. A blank for master type-bars, provided with a line of projections for the type-faces, the working sides of the said projections being equally spaced from one end of the bar.

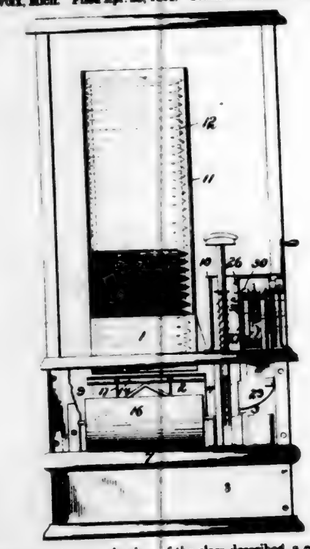
5. A blank for master type-bars provided with alined projections arranged in the order of their decreasing setwise dimensions from one end of the bar toward the other, the gaging or working sides of the projections being also spaced at equal intervals from one end of the bar.

6. A blank for master type-bars provided with alined projections for the type-faces, spaced longitudinally of the bar, one face of each of said projections being coincident with one face of the bar.

7. A blank for master type-bars provided with a line of spaced projections for the type-faces, having one face of each projection coincident with the side of the type-bar, and having the working sides of the respective projections spaced at equal intervals from one end of the bar.

8. A series of blanks for master type-bars, provided with alined projections for a line of master-type, the projections being similarly spaced on all of the bars, whereby the series of bars when engraved and assembled form a column of master type-faces alined in both directions.

707,524. COIN-ACTUATED VENDING MECHANISM. FRANK M. SEARS, Charlevoix, Mich., assignor of one-half to August Chaloupka, Charlevoix, Mich. Filed Apr. 26, 1901. Serial No. 57,396. (No model.)



Claim.—1. In a mechanism of the class described, a coin-receiving member, a main coin-guide, a supplemental coin-guide, said coin-guides consisting each of an upright coin-tube, the coin-receiving member being arranged to deposit the coin directly into the main coin-guide, a coin-actuated member projecting at one end into the coin-tube of said supplemental coin-guide, an operating member projecting into the coin-tube of said supplemental coin-guide and above said coin-actuated member, and the coin-tube of the main coin-guide communicating with the coin-tube of the supplemental coin-guide at a point between said coin-actuated member and said operating member.

2. In a mechanism of the class described, a coin-guide consisting of a coin-tube provided at a predetermined point with an inwardly-projecting spring-finger and provided at its top with a curved guide device, a rotary coin-receiving member arranged above the coin-tube and provided with a contracted coin-slot in which the coin is temporarily held, devices for rotating the coin-receiving member to deposit the coin in the coin-tube and over said curved guide device, and a cam-like device carried by the coin receiving member for forcing the coin past said spring-finger, the relative arrangement of parts being such that two coins may be simultaneously accommodated in upright file in the coin-tube between said coin-receiving member and said spring-finger, said cam-like device carried by the coin-receiving member operating to force the lowermost of said coins past said spring-finger.

3. In a mechanism of the class described, a coin-tube provided at its top with a curved guide device, a rotary coin-receiving member arranged above the coin-tube and provided with a contracted coin-slot in which the coin is temporarily held, devices for rotating the coin-receiving member to deposit the coin in the coin-tube and over said curved guide device, and tensional means for opposing the rotation of the coin-receiving member.

4. In a mechanism of the class described, a coin-guide, devices for temporarily checking the passage of a coin through the coin-guide, a pivoted coin-receiving member arranged above the coin-guide and provided with a contracted coin-slot in which the coin is temporarily held, devices for tilting the coin-receiving member to deposite the coin in the coin-guide, and devices carried by the coin-receiving member for forcing the temporarily-checked coin through the coin-guide, the relative arrangement of parts being such that two coins may be simultaneously accommodated in the coin-guide between said coin-receiving member and said devices for temporarily checking the passage of a coin through the coin-guide.

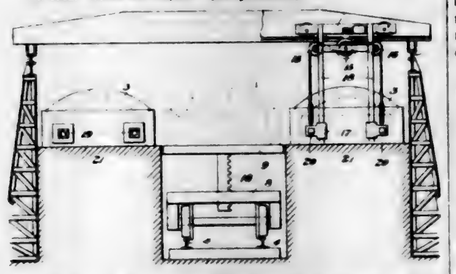
5. In a mechanism of the class described, a coin-actuated member; and an operating member comprising a coin-guide devices for temporarily checking the passage of a coin through the coin-guide, a movable coin-receiving member arranged to deposite the coin in the coin-guide, devices for operating the coin-receiving member, devices carried by the coin-receiving member for forcing the temporarily-checked coin through the coin-guide, (the relative arrangement of parts being such that the coin is deposited by the coin-guide in a position with respect to the coin-actuated member,) and means for actuating the coin-actuated member through the medium of the coin.

6. In a mechanism of the class described, a coin-actuated member; and an operating member comprising a coin-guide, a pivoted coin-receiving member arranged above the coin-guide and provided with a contracted coin-slot in which the coin is temporarily held, devices for operating the coin-receiving member, (the relative arrangement of parts being such that the coin is deposited by the coin-guide in a position with respect to the coin-actuated member,) and means for actuating the coin-actuated member through the medium of the coin.

7. In a mechanism of the class described, a coin-tube provided with an elongated slot, a movable delivery member, a connection-lever operatively connected with the delivery member and projecting at one end through said elongated slot, an operating-plunger, and a second coin-tube communicating with the first coin-tube at a point between the projecting end of the connection-lever and plunger whereby the connection-lever may be operated to move the delivery member through the medium of an interposed coin.

8. In a mechanism of the class described, a movable delivery member, a main coin-guide, a coin-receiver located in juxtaposition to the top of the main coin-guide and adapted to deposit the coin directly into the main coin-guide, a supplemental coin-guide, provided with a vertical slot, a pivoted lever operatively connected with the delivery member and projecting into said slot below the connection of the main and supplemental coin-guides, and an operating member projecting into said slot above such connection.

707,525. PROCESS OF MANUFACTURING COKE. JOHN W. SEAVER, Cleveland, Ohio, assignor to the Wellman-Seaver-Morgan Engineering Company, Cleveland, Ohio, a Corporation of Ohio. Filed June 9, 1902. Serial No. 110,751. (No specimens.)



Claim.—1. The process of manufacturing coke, consisting in assembling the charge to be coked, assembling the charge and the dome, moving the assembled charge and dome onto a fixed hearth, and coking the charge.

2. The process of manufacturing coke consisting in assembling the charge to be coked, introducing the said charge into a dome, moving said dome with its charge to a fixed hearth, and coking the charge.

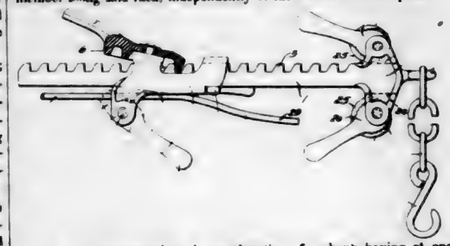
3. The process of manufacturing coke, consisting in assembling the charge to be coked, introducing said charge into the bottom of the dome, moving said dome with its charge to a fixed hearth, and coking the charge.

4. The process of manufacturing coke consisting in assembling the charge to be coked, bringing the charge to a charging position, removing the dome from the coking-hearth to a position over said charge, placing the charge in the dome, replacing the dome on the hearth, and coking the charge.

707,526. WIRE-STRETCHER. MARTIN R. SHIVE and FREDERICK J. HERBERT, Chicago, Ill.; said Shive assignor to said Herbert. Filed Nov. 22, 1901. Serial No. 83,260. (No model.)

Claim.—1. In a wire-stretcher, the combination of a shank having at one end a wire-clamp, a member slidably mounted on said shank, a wire-clamp secured to said member, a rack and spiral gear for moving said member along said shank, and means for throwing said rack and spiral out of mesh with each other to permit the movement of said member along said rack, independently of the rotation of said spiral.

2. In a wire-stretcher, the combination of a shank having at one end two independent wire-clamps, a member slidably mounted on said shank, a wire-clamp secured to said member, a rack and spiral gear for moving said member along said shank, and means for throwing said rack and spiral out of mesh with each other to permit the movement of said member along said rack, independently of the rotation of said spiral.

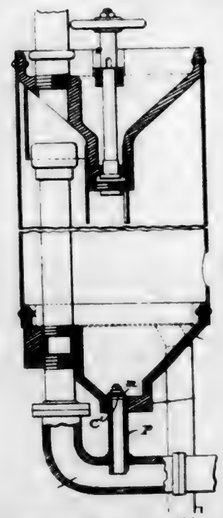


3. In a wire-stretcher, the combination of a shank having at one end a wire-clamp, a member slidably mounted on said shank, a wire-clamp secured to said member, a rack and spiral gear for moving said member along said shank, said member being adapted to be tilted on said shank so as to throw said rack and spiral out of mesh with each other, and a movable stop for preventing the accidental tilting of said member.

4. In a wire-stretcher, the combination of a shank having thereon a series of rack-teeth, a wire-clamp secured to one end of said shank, a member mounted on said shank and slidable longitudinally thereof, a wire-clamp secured to said member, a plate journaled on said member and having on one face a spiral thread in mesh with the teeth on said shank, a handle for rotating said plate and thereby causing said member to move along said shank, said member being adapted to be tilted on said shank so as to throw said spiral thread out of mesh with said rack-teeth, and a movable stop for preventing the accidental tilting of said member.

5. The combination of a rack, a member mounted on said rack and slidable longitudinally thereof, a plate pivoted to said member and having on one face a spiral thread in mesh with said rack, means for rotating said plate and thereby causing said member to move along said rack, and means for shifting said thread out of mesh with said rack to permit the movement of the member along the rack, independently of the rotation of the said plate.

707,527. SAND-BLAST APPARATUS. AMBROSE G. WARREN, Philadelphia, Pa., assignor of one-half to J. W. Paxson Company, Philadelphia, Pa., a Corporation. Filed Apr. 1, 1902. Serial No. 100,900. (No model.)

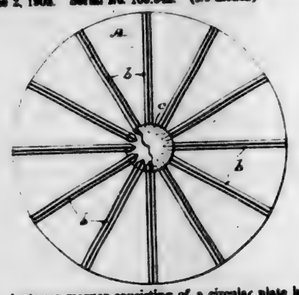


Claim.—1. A sand-blast apparatus comprising a closed casing or reservoir, having a substantially cone-shaped hopper-base, a sand-discharge opening therein, a communicating tubular sand-conduit leading therefrom to a combining-tube, a hand-hole opening in the inclined wall

of the conical hopper contiguous to said discharge-opening therein, and a removable cover therefor; said elements being constructed, combined and operating, substantially as set forth.

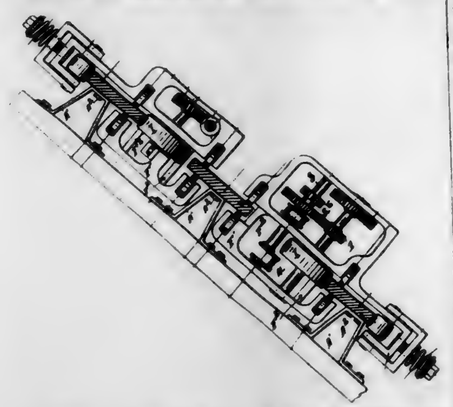
2. In a sand-blast apparatus, a closed casing from which sand is discharged by the impact of fluid-pressure to a combining-tube, said casing having a substantially cone-shaped hopper-base, a central discharge-opening at the apex of the conical hopper, and flat basal portion contiguous to said opening, a valve-plate covering said opening, a valve-spindle passing through said casing, and means to rotate said spindle and operate the valve-plate; substantially as described.

707,528. CHEESE-MARKER. JOSEPH WOLFINGER, Dundas, Wis. Filed June 2, 1902. Serial No. 109,842. (No model.)



Claim.—A cheese-marker consisting of a circular plate having one face thereof provided at regular intervals with radial ridges out of touch with one another at their inner ends, and a center disk covering said inner ends of the plate-ridges.

707,529. CANAL TOWING MECHANISM. STEPHEN W. WOOD, New York, N. Y. Filed Apr. 21, 1902. Serial No. 103,223. (No model.)



Claim.—1. The combination, in canal towing mechanism, of supporting-posts, parallel traction-rails supported in a vertical plane from such posts, an intermediate guide-rail supported from the posts, and motors grasping the traction-rails, each motor bearing with guide-wheels on the intermediate guide-rail.

2. The combination, in canal towing mechanism, of the posts, brackets extending therefrom, upper and lower traction-rails supported by said brackets, the upper rail extending downward and the lower rail extending upward from the face of their brackets, and an intermediate guide-rail supported by brackets, and having its edges projecting upwardly and downwardly in the direction of the traction-rails

3. The combination, in canal towing mechanism, of three track-rails arranged in parallelism beside the canal, suitable supports for said rails, motors arranged to move independently in the spaces between the two outer track-rails and the inner rail, and separate towing connections from said motors.

4. The combination with supporting-posts and upper and lower traction-rails, of independent motors on each rail, the upper motor having a traction-wheel at one edge and a gripping-wheel at the opposite edge of its rail, and the lower motor having its traction and gripping wheels in reverse relation to its rail.

5. The combination with the supporting-posts, and upper and lower traction-rails, of an intermediate guide-rail, a motor on the upper rail having wheels bearing on each edge thereof and guide-wheels bearing on the guide-rails, and a motor on the lower traction-rail with wheels bearing on each edge thereof and guide-wheels bearing on the guide-rail.

6. In canal traction mechanism, the posts having upper and lower traction-rails and an intermediate guide-rail, motors on each traction-rail having wheels gripping both edges of said rail and guide-wheels bearing on the outer and inner faces thereof, each of said motors having guide-wheels engaging the outer and inner faces of the guide-rail, all combined.

7. A towing-way consisting of three rails arranged in parallelism on suitable supports, and independent motors arranged to run in the spaces between said rails, traction-wheels on each motor arranged to bear on the appropriate rails, and guide-wheels arranged to bear on the guide-rail, all combined.

8. In combination with the parallel traction and guide rails, a motor-frame having a section located so as to move on the inner side of said rails, said frame-section being of greater height than the space between the rails.

9. The combination in a towing apparatus, of posts having traction-rails and a guide-rail supported therefrom, a motor-frame having a section within and a section without the plane of said rails, and a hooked extension of said frame extending around the traction-rail, a gripper-wheel supported by said extension and bearing on the traction-rail, and guide-wheels bearing on both rails.

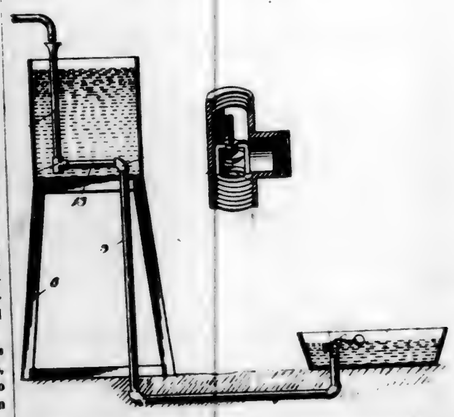
10. A towing-way consisting essentially of three rails arranged in parallelism along a canal, independent motors arranged to travel in either direction in the spaces between the outer rails and the inner rail, and to pass in one space without contact with motors in the other space, separate towing connections from each motor, and means for driving the different motors at different and variable speeds, all combined.

11. In a towing apparatus for canals, suitable supports alongside the canal and a plurality of traction-rails at different elevations on said supports, motors independently driven along said traction-rails, means for gripping each motor to its rail, means for towing a boat or boats leading from each motor, and means for regulating the speed of each motor independently of the speed of any other motor.

12. The combination, in canal towing mechanism, of an upper and a lower traction-rail, suitable supports therefor, independent motors traveling and moving in said rails on different horizontal planes, and tow-lines extending from the motors, so that one tow can pass over the other line.

13. The combination, in canal towing mechanism, of traction-rails arranged in different horizontal planes, independent motors moving along said rails, tow-lines extending from the motors so as to pass as described, and gripper mechanism by which the motors can be made to grip their respective rails.

707,530. STOCK-TANK. WAYNE C. WRIGHT, Amarillo, Tex. Filed Sept. 30, 1901. Renewed June 30, 1902. Serial No. 113,834. (No model.)



Claim.—1. In a device of the class described, the combination of a tank, a reservoir, a pipe connected with the tank and extending through the reservoir, said pipe having an opening leading from the reservoir, an inwardly-opening valve for the opening, and means for supplying water to the pipe above the valve.

2. In a device of the class described, the combination with a tank, of a reservoir, a pipe connected with the tank and leading upwardly through the reservoir, a float-valve mechanism for the pipe in the tank for controlling the passage of water from the pipe to the tank, an opening in the pipe communicating with the reservoir and having an inwardly-opening valve, said pipe extending above the water-level of the reservoir and having a flared upper end, and a supply-pipe leading to the flared end.

REISSUES.

12,020. BUTTON. GEORGE W. BUCHANAN, Chicago, Ill. Filed May 16, 1902. Serial No. 107,698. Original No. 673,698, dated May 7, 1901.

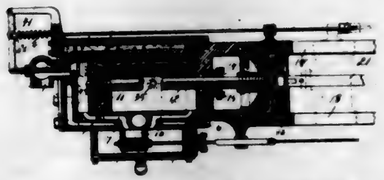
Claim.—1. The combination of two stud-buttons each comprising a base and a head, the base of one provided on its under side within the confines of its edge with means for engaging the head of the other.

2. The combination of two stud-buttons each comprising a base and a head, the base of one provided on its under side with a recess adapted to receive the head of the other button, and retaining mechanism for holding said head in said base, said retaining mechanism being within the confines of the edge of the base.

3. The combination of a pair of stud-buttons each comprising a base and a head, the base of one being provided with a recess adapted to receive the head of the other, and head-retaining mechanism contained entirely in the base, within said recess.

4. As a new article of manufacture the combination with a stud-button comprising a head, shank, and base, of a recess in said base adapted to receive the head of another stud-button, and head-retaining mechanism contained entirely in the base, within said recess.

12,021. GAS AND STEAM CONVERTIBLE ENGINE. GUSTAVE DAHLBERG, McDonald, JACOB CLICQUENNOI, Taylorstown, and ERNEST UHLIN, McDonald, Pa., assignors, by direct and mesne assignments, to D. C. & U. Gas Engine Company, Washington county, Pa. Filed Aug. 7, 1901. Serial No. 71,279. Original No. 633,338, dated Sept. 19, 1899.



Claim.—1. In a convertible engine, the combination, with a cylinder having a piston therein, of a steam-chest or fluid-chamber in communication with the cylinder, means for introducing and compressing an explosive mixture in the chest, and a passage for the compressed explosive mixture leading from the chest to the cylinder, substantially as set forth.

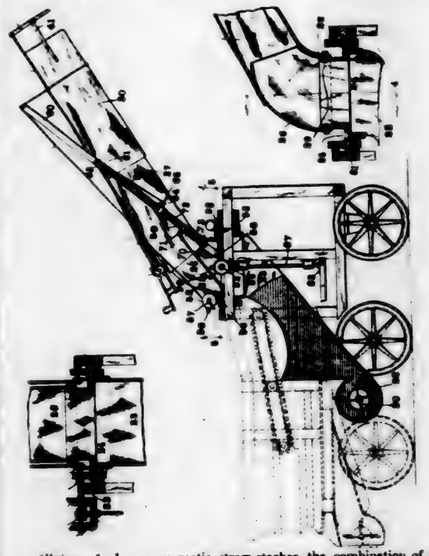
2. In a convertible engine, the combination, with a cylinder having a piston therein, of a steam-chest, steam-passages leading from the chest to opposite ends of the cylinder one of which is provided with a valve for closing the passage, said chest also provided with an inlet explosive-mixture passage, and with an outlet explosive-mixture passage leading to the cylinder, said passages arranged in conjunction with the piston and the steam-passages to permit an explosive charge to be drawn into the chest, compressed therein and the compressed explosive charge passed to the combustion end of the cylinder, substantially as set forth.

3. In a convertible engine, the combination, with a cylinder having a piston therein, of a steam-chest in communication with the cylinder adapted to receive an explosive mixture, a passage for the explosive mixture from the chest to one end of the cylinder, an inlet-port in the cylinder for admitting a compressed explosive charge, and a passage from the chest to the inlet-port, substantially as set forth.

4. In a convertible engine, the combination, with a cylinder having a piston therein, of a steam-chest in communication with the cylinder adapted to receive an explosive mixture, a gas-mixer provided with a valve, a connection between the mixer and the chest for the passage of an explosive mixture, a passage from the interior of the chest to one end of the cylinder, an inlet-port in the cylinder for admitting a compressed explosive charge, and a passage from the chest to the inlet-port, substantially as set forth.

5. In a convertible engine, the combination, with a cylinder having a piston therein, a steam-chest in communication with the cylinder by steam-passages leading from the chest to opposite ends of the cylinder, a valve located in one of the passages, means for admitting an explosive mixture to the chest, an inlet-port in the cylinder for the admission of a compressed explosive charge, a pipe connecting the chest with the inlet-port, said connecting-pipe and one of the steam-passages forming an explosive-mixture passage from one side of the piston to the other through the chest, substantially as set forth.

12,022. PNEUMATIC STACKER. JOHN H. ELWARD, Hutchinson, Kans., assignor, by direct and mesne assignments, to the Indiana Manufacturing Company, Indianapolis, Ind., a Corporation of West Virginia. Filed May 5, 1902. Serial No. 105,917. Original No. 688,400, dated Dec. 10, 1901.



Claim.—1. In a pneumatic straw-stacker, the combination of an ejector-fan, a rotary base, a duct-section upon and rotating with said base, a second duct-section supported upon and having its lower end vibratable relative to the rotary base, and connected with the base duct-section to form a continuation thereof, a third, outer, duct-section telescopically connected to the second section, said second and third sections being adapted to have their outer ends raised and lowered relatively to the base, means rotatable around the axis of the base for adjustably supporting the outer duct-section at different elevations, and means for positively moving the third outer duct-section longitudinally outward relative to the second section and also positively moving it inward relatively thereto, whereby the operator can, while the machine is in operation, move the outer duct-section to elongate or shorten the total duct, substantially as set forth.

2. In a pneumatic straw-stacker the combination of an ejector-fan, a rotary base, a duct-section supported upon and rotating with the base, a second duct-section supported upon and having its lower end vibratable relative to the rotary base, and connected with the base duct-section, a third outer duct-section telescopically connected to the second duct-section, said second and third sections being adapted to have their outer ends raised and lowered relatively to the base, means rotatable around the axis of the base, for adjustably supporting the outer duct-section at different elevations, and an adjusting mechanism having one member connected to the second duct-section, and a second member connected to the third outer duct-section, said members engaging with each other and being adapted to advance the third outer duct-section outward and to draw said duct-

section inward positively while the machine is in operation, substantially as set forth.

3. In a pneumatic straw-stacker, the combination of an ejector-fan, a duct leading therefrom, a base arranged to rotate around a vertical axis, an upwardly-extending duct-section connected to the base and rotating therewith, a second duct-section supported upon the rotary base and having its lower end connected with the base duct-section to form a continuation thereof, a third, outer, duct-section telescopically connected to the second duct-section, said second and third duct-sections being adapted to have their outer ends raised and lowered relatively to the base, means rotatable around the axis of the base for supporting the outer duct-section at different elevations, an adjusting mechanism having a longitudinally-movable member secured to, and upon the outside of, the third outer duct-section and a second member supported in rear of said outer duct-section, said two members mutually engaging with each other, and a crank, for actuating the last said member of said adjusting mechanism, substantially as set forth.

4. In a pneumatic stacker, the combination of an ejector-fan, a horizontally-rotary base or turn-table, a duct-section mounted on said base, a second duct-section connected with said base-section, a third outer, duct-section, telescopically connected with said second duct-section, devices for positively moving said outer duct-section longitudinally to either increase or decrease the length of the total duct, said devices comprising a movable member connected with the outer duct-section and extending longitudinally thereof and of the second section, to points adjacent to the inner end of said second section, and a relatively stationary member arranged adjacent to the base-section and engaging with the said movable member, whereby the operator can either increase or diminish the length of the duct from a point near the inner end thereof, while the machine is in operation, substantially as set forth.

5. In a pneumatic stacker, the combination of an ejector-fan, a turn-table or rotary base mounted to turn about a vertical axis, a tubular neck or stump secured to said base, a second duct-section having its inner end connected with said neck and having its outer end movable vertically, a third, outer, duct-section telescopically connected to said second duct-section, means adapted to turn about the axis of the rotary base, for supporting said third duct-section in line with the said second duct-section and the discharge-opening in the neck, means for adjusting both said second and third duct-sections vertically, and a rod connected at its outer end with the outer duct-section, and extending to points beyond the inner end of said third duct-section, for positively pushing the said third duct-section outwardly to lengthen the total duct and to draw said outer duct-section inwardly to shorten the total duct, substantially as set forth.

6. In a pneumatic stacker, the combination of an ejector-fan, a turn-table or rotary base mounted to turn about a vertical axis, a longitudinally-curved neck or stump mounted on said rotary base, an intermediate duct-section connected with said neck, an outer duct-section telescopically connected to said second duct-section, auxiliary upwardly-extending supports for said outer duct-section mounted on the rotary base, and extending to points beyond the outer end of the second duct-section, one or more winding-ropes bearing upon said auxiliary upwardly-extending supports and connected with said outer duct-section at a point near the outer end thereof, means for winding said rope or ropes to adjust both said outer and intermediate duct-sections vertically, and means extending to a point adjacent to the said neck for positively moving the outer duct-section outwardly to increase the length of the total duct and for positively moving said outer duct-section inwardly to shorten the total duct, substantially as set forth.

7. In a pneumatic stacker, the combination of an ejector-fan, a turn-table or rotary base adapted to rotate about a vertical axis, a duct-section mounted on said base to rotate therewith, a second duct-section communicating with said base-section, a third outer section telescopically connected with the said second duct-section, an auxiliary support having a member adapted to rotate about the axis of said rotary base and a member longitudinally adjustable of the first said member and extending to points beyond the outer end of said second duct-section, connections between the outer adjustable member of said auxiliary support and the third outer duct-section, means for simultaneously adjusting the outer and second duct-sections vertically, and means connected with the outer duct-section to positively move said section outwardly to increase the total length of the duct and to positively move said outer duct-section inwardly to shorten the total duct, substantially as set forth.

8. In a pneumatic stacker, the combination of a turn-table or rotary base, or main support, a fan below said support, a neck or "stump" mounted on and rotating with said rotary base, a stationary conduit connecting the said neck with the fan-chamber, a second duct-section connected with said base-section, an outer duct-section telescopically connected to the last-said duct-section, a deflector adapted to direct the path of material issuing from said outer duct-section, independent means for positively moving said outer duct-section outward to lengthen the total duct and positively moving said outer duct-section inward to shorten the total duct, and adjusting means connected with the deflector, and extending to a point adjacent to the turn-table or rotary base, whereby the operator can, while the machine is in operation, elongate or shorten the duct and adjust the deflector as desired, substantially as set forth.

9. In combination with the telescopic trunk, the deflector hinged to the outer trunk-section, an operating-rod attached to said deflector and extending back along the trunk, and operating means connected to said rod and mounted on and carried by the inner trunk-section, substantially as and for the purpose hereinbefore set forth.

10. In combination with the telescopic trunk and the guide attached to the outer section, a deflector hinged to said outer section, an operating-rod attached to said deflector and extending back through and beyond the guide, and operating means connected to the said rod, and mounted on the inner trunk-section, substantially as and for the purpose hereinbefore set forth.

11. In a pneumatic straw-stacker, the combination of an ejector-fan, a trunk or duct for wind and straw communicating with the fan-casing and having an inner section and an outer section telescopically connected to the inner section, a deflector at the outer end of the telescopic section, means for positively moving said outer telescopic section together with the deflector longitudinally of the duct, and means for adjusting the deflector independently of the telescoping section, whereby the deflector can be adjusted bodily toward and from the fan and also into different positions relative to the path of the air and straw, substantially as set forth.

12. In a pneumatic straw-stacker, the combination of an ejector-fan, a discharge trunk or duct communicating with the fan-casing and having an outer section adapted to be adjusted longitudinally of the trunk to vary its length, a horizontally-vibrating base-support for said trunk, a deflector at the outer end of the trunk, and two independent sets of adjusting devices carried by the vibrating base-support, one set for positively moving the outer section of said trunk inward or outward to vary the total length of the trunk, and the second set for positively adjusting the deflector relatively to the discharge end of said trunk, substantially as set forth.

13. In a pneumatic straw-stacker, the combination of an ejector-fan, a discharge trunk or duct communicating with the fan-casing, and having an outer section adapted to be adjusted longitudinally of the trunk to vary its length, a horizontally-vibrating base-support for said trunk, a deflector at the outer end of the trunk movable independently thereof and three independent sets of adjusting devices carried by the vibrating base-support, one set for positively moving the outer section of said trunk and the deflector inward or outward, a second set for positively adjusting the deflector relatively to the discharge end of said trunk, and a third set for adjusting the outer end of the trunk vertically bodily, substantially as set forth.

14. In a pneumatic straw-stacker, the combination of an ejector-fan, a discharge-trunk having an inner section communicating with the fan-casing, and an outer section adapted to be telescoped longitudinally on the inner section, a deflector at the outer end of said telescoping section, and adjusting mechanism for moving the telescoping section longitudinally, comprising a toothed wheel and rack one of which is supported stationarily relatively to the inner trunk-section, and the other of which is connected to the telescoping section, and devices independent of said wheel and rack for adjusting the deflector relatively to the telescoping section, substantially as set forth.

15. In a pneumatic straw-stacker, the combination of an ejector-fan, an escape-duct leading from the fan, a trunk adapted for the passage therethrough of wind and straw having its outer end vertically adjustable and its inner end supported at the end of the fan-duct to move vertically relatively thereto, said trunk being formed in two parts of which one can slide on the other and having its outer delivery end movable longitudinally while in operation to vary the position of the edge over which the straw escapes, a deflector situated at the outer end of the sliding part of the trunk, and adjustable relatively to the longitudinal axis thereof, adjusting mechanism for moving the deflector and the sliding part of the trunk toward and from the fan comprising two mutually-engaging devices, one connected to the inner part of the trunk and the other connected to the sliding part, and a crank for actuating the said adjusting mechanism, substantially as set forth.

16. In a pneumatic straw-stacker, the combination of an ejector-fan, a turn-table or rotary base mounted above said fan, a duct-section mounted on said base to rotate therewith and communicating with said fan-casing, a discharge-trunk having its inner end communicating with and movable relatively to the upper end of the base duct-section, ropes or cables for supporting the outer end of said trunk, means for adjusting said ropes to raise or lower the outer discharge end of the trunk, a pivotally-mounted deflector at the outer end of said trunk, a rod connected to said deflector and extending rearward along the trunk, and a locking device engaging said rod to hold the deflector in any position of adjustment, substantially as set forth.

17. In a pneumatic straw-stacker, the combination of an ejector-fan, a discharge trunk or duct communicating with the fan-casing, and having an outer section adapted to be adjusted longitudinally of the trunk to vary its length, a vibrating base-support for said trunk, a deflector at the outer end of the trunk movable independently thereof, and three independent sets of adjusting devices, one set for positively moving the outer section of said trunk and the deflector inward and outward, a second set for positively adjusting the deflector relatively to the discharge end of said trunk, and a third set for adjusting the outer end of the trunk vertically bodily, substantially as set forth.

18. In a pneumatic straw-stacker, the combination of an ejector-fan and its casing, a turn-table or rotary base mounted above said fan, a duct-section mounted upon said base to rotate therewith and communicating with said fan-casing, a discharge-trunk having its inner end communicating with and movable relatively to the upper end of the base duct-section, ropes or cables for supporting the outer end of said trunk, means for adjusting said ropes to raise or lower the outer discharge end of the trunk, a pivotally-mounted deflector at the outer end of said trunk, an operating member connected to said deflector and extending rearward along the trunk, and a locking device engaging said operating member to hold the deflector in any position of adjustment, substantially as set forth.

19. The combination with a threshing-machine of a pneumatic stacker adapted to remove and convey away the treated material therefrom, comprising a blast mechanism, a vibratably-movable longitudinally-extensible delivery-duct communicating with the blast mechanism, and means connected therewith for vibratably moving and other means for longitudinally extending and retracting said duct at will during the operation of the machine.

20. The combination with a threshing-machine of a pneumatic stacker, comprising a blast mechanism, a horizontally-swiveled vertically-adjustable longitudinally-extensible material-delivery duct communicating with the blast mechanism, and means for horizontally moving vertically adjusting and positively extending and retracting the movable portion of said duct during operation, substantially as set forth.

21. The combination, in a pneumatic stacker adapted to convey away the treated material from a threshing-machine, of a suitable stationary fan-housing, a fan therein, a stationary duct-section connected to the fan-housing, a second duct-section vibratably connected to said stationary duct-section, a third duct-section telescopically connected to said second duct-section, a deflector secured to the outer end of said telescopic section, means for adjusting said deflector, means for adjusting said telescopic section in respect to said second duct-section, and means for swinging said second duct-section carrying said telescopic section and said deflector in respect to said stationary duct-section, whereby said duct may be swung to various positions, its total length varied, and the delivery of straw therefrom adjustably controlled, all while the machine is in operation.

22. The combination, with a threshing-machine, of a pneumatic conveyer, adapted to convey material away from said machine, comprising a fan-housing fixedly mounted in respect to said machine at its delivery end, a fan in said housing, a duct leading from said fan-housing, comprising a fixed section, a second section flexibly united to said fixed section, a third section telescopically connected to said second section, a deflector mounted on the discharge end of said third section, means for adjusting and moving said second and third sections both horizontally and vertically in respect to said stationary section, and other means for moving said third section longitudinally in respect to said second section, whereby the delivery or discharging point may be raised or lowered, swung from side to side, and moved in and out toward and from the machine, thus enabling the material to be delivered at any desired point on the stack, and enabling the stack to be made of any desired dimensions, substantially as set forth.

23. In a pneumatic stacker, the combination of a blast-fan, its housing, a conduit leading therefrom to a ring or turn-table, said turn-table, a stump or neck mounted thereon, a main delivery trunk or duct vibratably mounted in respect to said neck and composed of two sections one telescopically mounted in respect to the other, means for rotating said turn-table carrying the delivery trunk or duct, means for vibrating said trunk or duct, and means for telescopically moving one duct-section on the other, all said operating means being arranged at or near the base of the structure whereby the same can be conveniently manipulated from a convenient point during the operation of the machine.

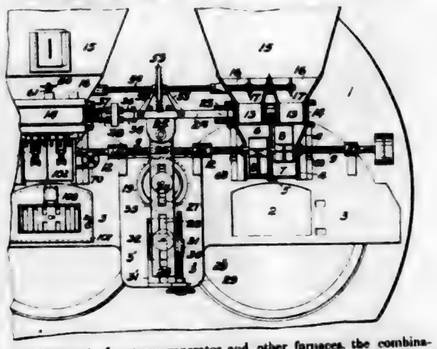
24. In a pneumatic stacker adapted to remove and convey away the treated material from a threshing-machine, the combination of a blast-fan, its housing, a primary conduit or duct section leading therefrom, a main conduit or duct composed of two duct-sections telescopically connected, a union intermediate said primary duct and said main duct comprising two joints whereby motion in two directions is provided for, means for swinging said main duct in respect to said primary duct, and means for telescopically moving one of the main-duct sections in respect to the other, whereby the material can be delivered at points gradually farther from the thresher without altering the elevation of the conduit or chute and whereby the vertical position of the delivery end of the chute can be varied at any time, so that the material cannot only be carried first nearer to and then farther from the thresher, but can also be piled higher and higher, as well as taken farther and farther out.

25. The combination with a threshing-machine, of a pneumatic stacker adapted to convey away the treated material therefrom, comprising a fan-housing, a fan therein, a duct-section leading from said housing, a second duct-section flexibly connected to said first duct-section, a third duct-section telescopically connected to said second duct-section, a deflector adjustably mounted at the discharging end of said third duct-section, means for adjusting said deflector, means extending down to near the lower end of the second duct-section for adjusting said third or telescopic duct-section in respect thereto, whereby said adjustment may be effected while the machine is in operation, and means for swinging the structure comprising said second and third duct-sections both vertically and horizontally.

26. In a pneumatic straw-stacker, the combination of a fan-housing, a fan therein, a rotary base or turn-table, a duct-section leading from said fan to said base, a duct-section supported upon and rotating with the base, a second duct-section supported upon said base and united to the base duct-section by a movable or yielding connection, a third outer duct-section telescopically connected to the second duct-section, said second and third duct-sections being adapted to have their outer ends raised and lowered relatively to the base, means for adjustably supporting the outer duct-section at different elevations, a duct-section telescopically-adjusting mechanism having one member connected to the second duct-section and a second member connected to the third outer duct-section, said members engaging with each other and being adapted to advance the third outer duct-section outwardly and to draw said duct-section inwardly, positively, while the machine is in operation, a deflector at the discharge end of the delivery-duct, and means for adjusting said deflector.

27. The combination, with a threshing-machine, of a pneumatic stacker adapted to remove and convey away the treated material therefrom, comprising an ejector-fan, a turn-table or rotary base, a duct-section leading from said fan to said base, a second duct-section connected thereto by motion-permitting joint construction, a third outer duct-section telescopically connected with said second duct-section, devices for positively moving said outer duct-section longitudinally to either increase or decrease the total length of the duct, said devices comprising a movable member connected with the outer duct-section and extending longitudinally thereof and of the second duct-section to a point adjacent to the inner end of said second duct-section, and a relatively stationary member arranged adjacent to the base-section and engaging with and adapted to impart motion to said movable member, whereby the operator can either increase or diminish the length of the duct from a point near the inner end thereof while the machine is in operation, substantially as set forth.

12,028. FUEL-FEEDING APPARATUS. WILLIAM G. STOBBS, Blackburn, England, assignor to Smoke Preventer Company, Limited, Blackburn, England. Filed Mar. 29, 1902. Serial No. 100,631. (Original No. 680,818, dated Aug. 20, 1901.



Claim.—1. In steam-generator and other furnaces, the combination therewith of one or more slides, or fuel-feed boxes, working at right angles to the boiler-front; a fan-box and fan, or fans, beneath said slides; a fuel-feed hopper above said fan-box and slide or slides; a bed or base plate carrying said fan-box and hopper; a rocking lever with variable fulcrum; means for imparting the motion of said lever to the said slides and controlling the movements of said slide or slides; inclined articulated fuel-distributing plates, a supporting-bracket therefor and means for adjusting

and indicating the position of such plates and supporting-bracket, as set forth.

2. In steam-generator and other furnaces, the combination of one or more slide-boxes; a screw upon the end of each box; a nut on said screw with finger or extension formed with an opening, a "swivel" or crank with fork engaging with said finger; a rod with pin engaging with fork on said swivel; a bracket carrying said rod; a cross-bar carrying said bracket; a lever suspended from said cross-bar; a fulcrum engaging with said lever; an adjustable bracket or block carrying said fulcrum; a screw for adjusting said block; an eccentrically-mounted block engaging with the upper portion of said lever; a wheel carrying said block and driven by any suitable means, as set forth.

3. In steam-generator and other furnaces, the combination of a supporting-bracket; a distributing-plate hinged at an angle thereto; a further distributing-plate hinged to the top edge of said plate, and means for maintaining said plates in proper relation to each other, as set forth.

4. In combination, a supporting bracket or brackets, two sets of inclined articulated distributing-plates; a lever or levers for supporting said bracket, or brackets, and plates; means for effecting the adjustment of said lever or levers; a set of links or rods connected with said plates, a screwed boss through which each of said rods passes; a support or bracket for carrying said boss; and a hand-wheel for operating said boss with index and pointer, as set forth.

5. In combination, the fuel-box and slide, a rocking lever connected to the slide; a fulcrum engaging said lever; a block carrying said fulcrum; a screw for adjusting said block; a worm-wheel; a pin or stud eccentrically mounted upon the worm-wheel engaging the upper portion of said lever; a worm gearing with said worm-wheel; a shaft carrying said worm; and means for driving the said shaft.

6. In combination, a cross-bar, a rocking lever, a fulcrum engaging with said lever, a sliding block carrying said fulcrum, a screw for adjusting said block, a bracket through which said screw passes, a collar for preventing said screw traveling, as set forth.

7. In combination, a cross-bar, a pawl or pawls upon said cross-bar; a shaft above said pawls; a face ratchet-wheel upon said shaft; a set of feed-hoppers, and a set of agitators on the said shaft situated in the throats of the feed-hoppers, as set forth.

8. In combination, a set of bed-plates and fan-boxes, one plate for each fan-box, and one for supporting the gearing mechanism, so arranged as to allow for their independent expansion or contraction, as set forth.

9. In combination, a fan-casing with tapered sides, a vertical partition for dividing the said fan-casing, a frame upon the said casing with an opening for inspection of the feed, a lid or cover for the said opening, a relief-door in the fan-casing, a fixed bracket and spring for holding the said door normally closed, and a casing for containing slide-box-operating mechanism, as set forth.

10. The herein-described center motion comprising a lever, a rising-and-falling fulcrum therefor with means for adjusting the same, worm-gearing and an eccentric pin for connecting the worm-gearing with the lever, substantially as described.

DESIGNS.

36,009. RING. ANDREAS BECKER, Vallsburg, N. J., assignor to Bracher, Becker & Barnett, Newark N. J., a Firm. Filed June 14, 1902. Serial No. 111,735. Term of patent 7 years.

Claim.—The ornamental design for a ring, substantially as shown and described.

36,010. HANDLE FOR BUTTON-HOOKS, PAPER-CUTTERS, OR SIMILAR ARTICLES. THEODORE W. FOSTER, Providence, R. I. Filed June 30, 1902. Serial No. 113,581. Term of patent 7 years.

Claim.—The ornamental design for the handle of a button-hook, paper-cutter or similar article, as herein shown and described.

36,011. BACK FOR TOILET-BOXES, MIRRORS, OR SIMILAR ARTICLES. THEODORE W. FOSTER, Providence, R. I. Filed June 30, 1902. Serial No. 113,582. Term of patent 7 years.

Claim.—The ornamental design for the back of a toilet-box, mirror or similar article, as herein shown and described.

36,012. BACK FOR HAND-MIRRORS, BRUSHES, OR SIMILAR ARTICLES. LOUIS C. PORTER, Attleboro, Mass., assignor to the James R. Blake Company, Attleboro, Mass. Filed Dec. 12, 1901. Serial No. 85,710. Term of patent 3½ years.

36,012

Claim.—The ornamental design for the back of a hand-mirror, brush, or similar article, as herein shown and described.

36,013. SOUVENIR-PLATE. LOUISA WOHLTMAN, New York, N. Y. Filed June 26, 1902. Serial No. 112,308. Term of patent 14 years.

Claim.—The ornamental design for a souvenir-plate as herein shown and described.

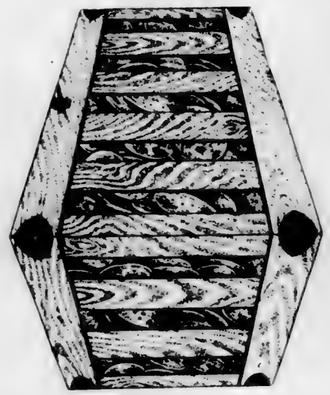
36,014. COFFEE OR TEA POT. HENRY HUTZLER, New York, N. Y. Filed June 19, 1902. Serial No. 112,295. Term of patent 7 years.

Claim.—The ornamental design for a coffee or tea pot herein shown and described.

36,015. ZITHER-BODY. CARL E. BROWN, Columbus, Ohio. Filed June 13, 1902. Serial No. 111,588. Term of patent 14 years.

Claim.—The ornamental design for a zither-body as herein shown and described.

36,016. BOX OR CARTON. FRANK GORTZ, Manchester, Conn. Filed May 27, 1902. Serial No. 109,949. Term of patent 7 years.



Claim.—The ornamental design for a carton or box as herein shown and described.

36,017. FONT OF LOWER-CASE PRINTING-TYPE. BERNE NABALL, Chicago, Ill., and GUSTAVE A. BARBER, London, England, assignors to the Linotype Company, Limited, London, England. Filed Jan. 17 1902. Serial No. 116,008. Term of patent 14 years.

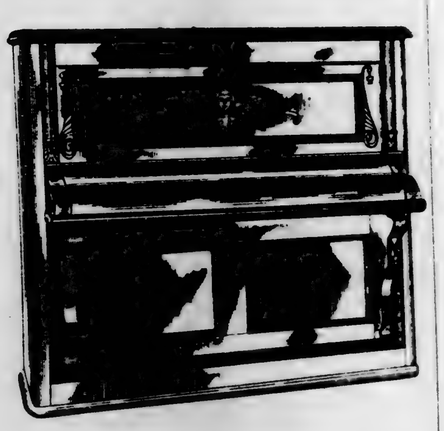
Claim.—The ornamental design for a font of upper-case printing-type substantially as herein shown and described.

36,019. FOLDING-BED CASE. CHARLES L. GAMER, Chicago, Ill. Filed June 23, 1902. Serial No. 112,953. Term of patent 7 years.

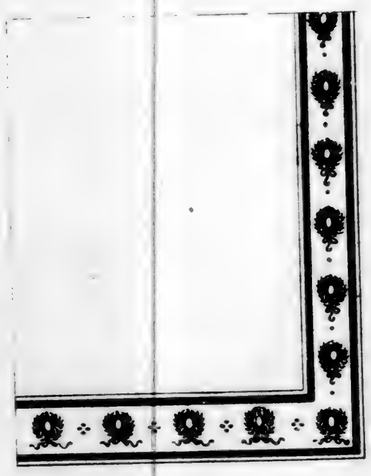


Claim.—The ornamental design for a folding-bed case, substantially as herein shown and described.

36,020. LACE CURTAIN. ARTHUR BURGESS, Philadelphia, Pa., assignor to Joseph H. Bromley, Philadelphia, Pa. Filed June 25, 1902. Serial No. 113,174. Term of patent 7 years.

Claim.—The ornamental design for a lace curtain substantially as shown and described.

36,021. LACE CURTAIN. ARTHUR BURGESS, Philadelphia, Pa., assignor to Joseph H. Bromley, Philadelphia, Pa. Filed June 25, 1902. Serial No. 113,175. Term of patent 7 years.



Claim.—The ornamental design for a lace curtain substantially as shown and described.

TRADE-MARKS

REGISTERED AUGUST 19, 1902.

38,787. DRESS-SILKS. LIBERTY SILK CO., New York, N. Y. Filed Mar. 10, 1902.

GRANDMOTHER

The word "GRANDMOTHER." Used since February 6, 1902.

38,788. MOHAIR, ALPACA, AND LUSTER-WOOL LININGS. R. G. WILLIAMS & CO., Bradford, England, and New York, N. Y. Filed July 1, 1902.

The word "AURORA," produced in a circle above the representation of a sunrise, also appearing in the circle. Used since 1899.

38,789. COTTON THREAD. NEW ENGLAND COTTON YARN COMPANY, Jersey City, N. J., and New Bedford, Mass. Filed July 5, 1902.

The word "QUAKER" and a circle inclosing the same. Used since June 1, 1901.

38,790. COTTON THREAD. NEW ENGLAND COTTON YARN COMPANY, Jersey City, N. J., and New Bedford, Mass. Filed July 5, 1902.

The word "MAXIMA" and a circle inclosing the same. Used since June 1, 1901.

38,791. ELASTIC OR CUSHION HEELS AND SOLES FOR BOOTS AND SHOES. FRANK W. WHITCHER & CO., Boston, Mass. Filed July 12, 1902.

NOJAR

The word "NOJAR." Used since March 1, 1900.

38,792. CHILDREN'S SHOES. WATSON PLUMMER SHOE CO., Chicago, Ill. Filed Mar. 31, 1902.

The representation of a little district school-house having printed across one side thereof the words and numeral "DISTRICT NO. 3," set in the midst of a landscape scene, the foreground of which consists of a playground with school-children at play therein, while the background is a perspective of meadow, trees, and hills, the whole being inclosed in an oval-shaped border of solid color and considerable and uniform thickness. Used since July 24, 1883.

38,793. BOOTS AND SHOES. FRANK M. FARGO, Philadelphia, Pa. Filed May 24, 1902.

"Ping=Pong"

The compound word "PING-PONG" in quotation-marks and the representation of two crossed rackets and a ball between the ends of the rackets. Used since April 1, 1902.

38,794. LEATHER SHOES. ANGLO-SAXON SHOE CO., Boston, Mass. Filed June 2, 1902.

The representation of an eagle holding in its beak and claws a ribbon on which is the hyphenated word "ANGLO-SAXON." Used since May 1, 1902.

38,795. LEATHER. Brown & Cobb, Boston, Mass. Filed Feb. 15, 1902.

WAVE

The word or term "WAVE." Used since February 7, 1902.

38,796. HAT-CLEANING COMPOUNDS. RIVERSIDE CHEMICAL COMPANY, Paterson, N. J. Filed July 22, 1902.

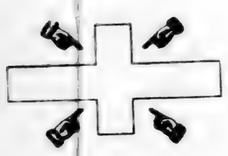
PAN-STRAW

The hyphenated word "PAN-STRAW." Used since July 11, 1902.

38,797. WRITING-INKS. THE CARTER'S INK CO., Boston, Mass., and New York, N. Y. Filed Mar. 31, 1902.

The representation of two leaves of old parchment attached to each other along one side by a lacing-cord and having the representation of a seal securing a folded ribbon imprinted upon the outer leaf, the seal representing an old ink-horn crossed by a quill, by the side of the leaves of parchment appearing the representation of an old ink-horn with its holding and attaching means and a quill, the quill being imposed upon the ink-horn, all appearing upon a contrasting rectangular background. Used since March 21, 1902.

38,798. SALVES. HANNAH WELCH, Philadelphia, Pa. Filed June 10, 1902.



The representation of a cross having two wings thereof longer than the others and of hands pointing thereto. Used since December 16, 1871.

38,799. CERTAIN NAMED MEDICAL COMPOUNDS. GEORGE R. WHITE, Boston, Mass. Filed June 3, 1902.

IRONOIDS

The word "IRONOIDS." Used since January 1, 1902.

38,800. CERTAIN NAMED MEDICAL COMPOUNDS. FARBWERKE, VORM. MEISTER, LUCIUS & BRÜNING, Höchst-on-the-Main, Germany. Filed Apr. 25, 1902.

VALYL

The word "VALYL." Used since October, 1901.

38,801. CERTAIN NAMED AMMUNITION. THE PETERS CARTRIDGE CO., Cincinnati, Ohio. Filed Mar. 22, 1902.

PREMIER

The word "PREMIER." Used since March 22, 1902.

38,802. LAXATIVE MEDICINES. THE PRUNETTA PHARMACAL CO. New York, N. Y. Filed June 24, 1902.

PRUNETTA

The word "PRUNETTA." Used since May 15, 1902.

38,803. LIQUID RHEUMATIC CURE. FRANK J. A. WALL, Kansas City, Mo. Filed June 23, 1902.

A photograph of John Wall, registrant's father, arranged in a panel in the representation of a red brick wall. Used since February 1, 1902.

38,804. TABLETS FOR BLOOD AND NERVOUS DISORDERS. PEARSON DRUG CO., Chicago, Ill. Filed Feb. 20, 1902.

IRON-UP

The hyphenated word "IRON-UP." Used since October, 1901.

38,805. BLOOD-TONIC. MARTIN D. PERKINS, Jamestown, N. Y. Filed July 1, 1893.

CACITO

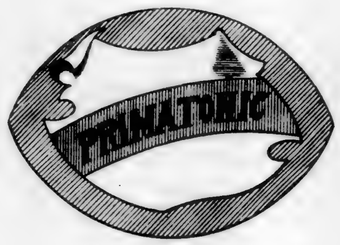
The word "CACITO," overarching the representation of a growing cactus. Used since June 10, 1893.

38,806. TONIC. FRANK L. BEGUE, Newark, Ohio. Filed July 1, 1902.

CEL-PEP-KO

The hyphenated word "CEL-PEP-KO." Used since February 28, 1900.

38,807. TONIC. INDEPENDENT BREWING ASSOCIATION, Chicago, Ill. Filed June 27, 1902.



The word "PRIMATONIC," arranged on a panel or band extending on a curved line diagonally across a shield, with a surrounding border for the shield having curved edges coming to a central point on each end of the panel or band, the shield, the border, and the letters forming the arbitrary word "Primatonic" having contrasting colors. Used since 1900.

38,808. LAGER-BEER. INDEPENDENT BREWING ASSOCIATION, Chicago, Ill. Filed July 1, 1902.

Prima

The word "PRIMA." Used since 1892

88,809. BEER. INDEPENDENT BREWING ASSOCIATION, Chicago, Ill. Filed July 3, 1902.

The representation of a lady in the costume of a prima donna draped in a loose garment falling from the shoulders, with sandals on her feet and having her arms and hands extended and carrying a garland of flowers wreathed over her head and falling from one shoulder. Used since 1892.

88,810. GINGER-ALE. STANDARD BOTTLING & EXTRACT CO., Boston, Mass. Filed Aug. 10, 1901.

The words "WHITE HOUSE," with the representation of the White House. Used since May 13, 1901.

88,811. WHISKY. JAMES GORDON LITZ, Cincinnati, Ohio. Filed May 6, 1902.

THREE · RIBBONS

The words "THREE RIBBONS," associated with the representation of three ribbons united at their upper ends and hanging loosely at their lower ends. Used since April 4, 1902.

88,812. WINES AND BRANDIES. SIEGEL-COOPER CO., New York, N. Y. Filed July 2, 1902.

QUEEN QUALITY

The words "QUEEN QUALITY" and the representation of three crowns. Used since June 2, 1902.

88,813. VINEGAR. H. J. HEINZ CO., Allegheny, Pa. Filed July 8, 1902.

REX AMBER

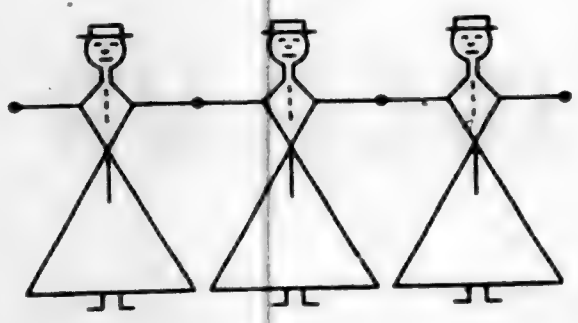
The words "REX AMBER." Used since June 1, 1902.

88,814. COFFEE. WOOLSON SPICE COMPANY, Toledo, Ohio. Filed Apr. 19, 1902.

The words "BETSEY ROSS" and the representation of a woman seated at a table sewing on an American flag, framed in a wreath of laurel, the whole being surrounded by a rectangular panel-border ornamented with scrollwork. Used since June 25, 1901

88,815. COCOA AND COCOA PREPARATIONS. KAKAO-COMPAGNIE THEODOR REICHARDT, GESELLSCHAFT MIT BESCHRÄNKTER HAFTUNG, Wandsbek, Germany. Filed May 19, 1902.

VIRGIN



The word "VIRGIS" and a diagrammatic representation of three female figures with outstretched arms and joining hands. Used since September, 1898.

38,816. BREAD. C. F SCHUPP & SON, Albany, N. Y. Filed May 14, 1902.

B B B

Three capital "B's," as follows: "B B B." Used since May 1, 1902.

38,817. PERIODICALS. THE PHELPS PUBLISHING COMPANY, Springfield, Mass. Filed May 21, 1902.

GOOD HOUSEKEEPING

The words "GOOD HOUSEKEEPING." Used since 1889.

38,818. PAPER BAGS AND WRAPPING-PAPER. EAGLE PAPER CO., Richmond, Va. Filed Apr. 4, 1902.

The representation of an ox. Used since July 1, 1898.

38,819. CERTAIN NAMED PHOTOGRAPHIC GOODS. CENTURY CAMERA COMPANY, Rochester, N. Y. Filed Mar. 21, 1902.

CENTURY

The word "CENTURY." Used since February, 1901.

38,820. TYPE-WRITER RIBBONS. THE MILLER, BRYANT, PIERCE CO., Aurora, Ill. Filed June 13, 1902.

The representation of the head of an elk together with the word "ELK." Used since May 1, 1902.

38,821. CERTAIN NAMED SPECTACLE AND EYEGLASS FRAMES AND MOUNTINGS. DUPAUL YOUNG OPTICAL CO., Southbridge, Mass. Filed May 29, 1902.

A small circle with a straight line extending outward therefrom. Used since April 1, 1902.

38,822. CERTAIN NAMED SPECTACLE AND EYEGLASS FRAMES AND MOUNTINGS. DUPAUL YOUNG OPTICAL CO., Southbridge, Mass. Filed May 29, 1902.

A T-shaped figure. Used since May 1, 1902.

38,823. RAZORS, KNIVES, SCISSORS, AND SHEARS. ALBERT L. SILBERSTEIN, New York, N. Y. Filed June 11, 1902.

The words "CARBO MAGNETIC" and the conventional representation of flashes. Used since May, 1895.

38,824. RAZOR-STROPS. A. J. JORDAN CUTLERY CO., St. Louis, Mo. Filed July 12, 1902.

The words "DRY CLIMATE" and a circular figure intended as a representation of the sun, there being a series of lines extending radially from the figure. Used since April 25, 1902.

38,825. INCANDESCENT ELECTRIC LAMPS. NATIONAL ELECTRIC LAMP CO., Cleveland, Ohio. Filed July 23, 1902.

NATIONAL

The word "NATIONAL." Used since June, 1901.

38,826. GAS-BURNERS. GEO. BRAY & CO., Leeds, England. Filed July 22, 1902.

MYTA

The word "MYTA." Used since November 15, 1901.

38,827. GAS-BURNERS. GEO. BRAY & CO., Leeds, England. Filed July 22, 1902.

ELTA

The word "ELTA." Used since November 15, 1901.

38,828. GAS-BURNERS. DEMETRIUS M. STEWARD, Chattanooga, Tenn., and New York, N. Y. Filed July 12, 1902.

WONDER

The word "WONDER." Used since March 1, 1897.

38,829. HYDRAULIC AIR-PUMPS. THE CLEVELAND FAUCET CO. Cleveland, Ohio. Filed July 5, 1902.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

REYNOLDS v. BEAN.

Decided July 2, 1902.

INTERFERENCE—PRELIMINARY STATEMENT BY ASSIGNEE.

Where an inventor refuses to file a preliminary statement and the records show that the assignee was diligent in endeavoring to obtain a statement from the inventor, *Held* that a statement made by the assignee should be accepted even though filed shortly after the expiration of the time for filing preliminary statements.

APPEAL on motion.

CAR-LOADER.

Application of Earl H. Reynolds filed September 5, 1901, No. 74,427. Patent granted John C. Bean April 24, 1900, No. 648,064.

Mr. Wm. O. Belt for Reynolds.

Messrs. Hensey & Gough for Bean.

ALLEN, *Commissioner:*

This is an appeal by Reynolds from a decision of the Examiner of Interferences granting the motion of the Ideal Car Loader Company for leave to file a preliminary statement and accepting the said statement.

The records show that the Ideal Car Loader Company is the assignee of the patentee Bean and that when this interference was declared the officers of the assignee company did not know his whereabouts. Efforts were made to locate him which were not successful until after the time for filing the preliminary statement had expired. The time for filing the preliminary statement was consequently extended.

Bean was subsequently located; but a misunderstanding seems to have arisen between him and his assignee with regard to the preliminary statement.

It appears from a letter filed by J. R. Martin, the president of the Ideal Car Loader Company, that Bean was willing to make affidavit that he is the inventor of the car-loader and to the date of his invention, but that he would not state that he is a party to this interference, as he had disposed of his entire interest in the patent which is involved.

A copy of the statement presented to Bean for execution was filed, but returned for signature. The time for filing the statement was again extended.

It would seem that a statement could have been prepared which would have satisfied the requirements of this Office and the conscience of Bean.

Three weeks after the time had expired a statement was filed by J. R. Martin, the president of the assignee company. This statement concludes as follows:

> That the dates named in the foregoing paragraph were furnished by the said Bean, who refused to sign a preliminary for the reason that having no interest in the said Letters Patent he declines to be a party to the interference which is adjudged to exist with a pending application of Earl H. Reynolds.

It clearly appears that the failure to file a statement by Bean within the proper time was not due to negligence and that the admission of the statement now on file will not injure Reynolds, except as the true state of facts will injure him. To refuse to admit the statement might result in granting a patent to Reynolds, when he is not the prior inventor. Such a contingency should be guarded against.

It is believed that in justice to all parties concerned the statement now on file should be accepted. (*Whitney* v. *Gibson*, 86 O. G., 1983; *Silver* v. *Eustis*, 98 O. G., 2361.)

The decision of the Examiner of Interferences is affirmed.

EX PARTE WHITMAN GROCERY COMPANY.

Decided June 30, 1902.

TRADE-MARK—"MINUTE" FOR COFFEE—DESCRIPTIVE.

The word "Minute" should not be registered as a trade-mark for malted cereal coffee, since it is descriptive of a quality or characteristic of the coffee, meaning that it is of such a character as to be prepared for use in a minute.

ON appeal.

TRADE-MARK FOR MALTED CEREAL COFFEE.

Application filed April 28, 1902, No. 65,682.

Mr. Ellis Spear for the applicant.

ALLEN, *Commissioner:*

This is an appeal from a decision of the Examiner of trade-marks refusing to register the word "Minute" as a trade-mark for malted cereal coffee.

Registration has been refused because, in the opinion of the Examiner, the word is descriptive of a quality or characteristic of the goods, meaning that the coffee is of such a character as to be prepared for use in a minute.

The decision of the Examiner was right and is in accordance with the decision of the circuit court of appeals in the case of *Bennett et al.* v. *McKinley et al.*, (65 Fed. Rep., 505,) in which it was held that—

the word "Instantaneous" is not a valid trade-mark, as applied to a preparation of tapioca which is distinguished from other preparations of that article by reason of its adaptability for immediate use, without the preliminary soaking required by other preparations. (Syllabus.)

The decision of the Examiner of Trade-Marks is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

FUNK *v.* MATTESON *v.* HAINES.

Decided June 23, 1902.

1. INTERFERENCE—SENIOR APPLICANT—JUNIOR APPLICANT—BURDEN OF PROOF—PRIORITY OF INVENTION.

H. being the senior party, the first to apply to the Patent Office, has *prima facie* the priority of right, and the *onus* of proof is upon any junior applicant to show not only priority of invention, but he must also show that he has used reasonable diligence in adopting and perfecting his invention, for in such a case the mere conception without actual reduction to practice within a reasonable time does not avail a junior party making the claim.

2. SAME—SAME—SAME—SAME.

Whoever first perfects a machine is entitled to the patent therefor and is the real inventor, although others may have previously had the idea and made some experiments toward putting it in practice, subject, however, to this qualification, that if the party who conceives the invention was at the time of a second invention by another party using reasonable diligence in perfecting the same he is entitled to be recognized as the first inventor, although the second to conceive may have been the first to reduce to practice, either actual or constructive. (*Agawam Co.* v. *Jordan*, 7 Wall., 583.)

3. SAME—PRIORITY—REDUCTION TO PRACTICE—WHAT IS NECESSARY.

In order to constitute a patentable invention, there must be more than mere progress to an end, however near that progress may have approximated to the end in view. The law requires not conjection, but certainty, and where the question relates to a machine the conception must have been clothed in substantial form, which demonstrated at once its practical efficiency and utility. (*Coffin* v. *Ogden*, 18 Wall., 120.)

4. SAME—SAME—PROOFS—ALLEGATION IN PRELIMINARY STATEMENTS.

In the production of proof in matters of interference the parties must be held strictly to the dates set forth in their preliminary statements.

5. SAME—SAME—CONCEPTION—DELAY IN REDUCTION TO PRACTICE—EFFECTS OF.

Assuming the truth of the statement contained in the preliminary statement of F. or even that contained in his testimony as to the time of conception of the invention, the great delay in attempting to complete and reduce the invention to practical operation is entirely without explanation and must consequently give rise to a strong presumption against his pretensions.

6. SAME—SAME—BURDEN OF PROOF.

H. being the first to reduce to practice and the first to apply to the Office must be presumed to be an original inventor of the machine which it is conceded he built and operated and for which he was the first to make an application for a patent. F. controverts this right of H., and it is incumbent upon him to show by clear and indubitable proof that the presumption in favor of H. is not well founded and that the right is in himself. Such proof F. has failed to produce, and priority of invention is therefore awarded to H.

Messrs. Munn & Co. for the appellant.
Mr. T. Walter Fowler for the appellee.

ALVEY, *C. J.*:

This is an appeal from the Commissioner of Patents, in the matter of interference between the application of Charles M. Funk, filed June 12, 1900; the application of Walter C. Matteson, filed December 18, 1899, and the application of George W. Haines, filed December 29, 1898. The number of this interference is 20,436, and relates to improvement of harvesters.

The declaration of the issue is formulated in three counts, as follows:

1. In a side-wheel harvester, the combination with a main frame, of supporting-wheels, bearings for the wheels movable relative to the frame, screws connecting the main frame and the bearings for changing the vertical position of the wheels relative to each other, and means for actuating said screws.
2. A thresher supported on wheels placed on opposite sides of it, and having screws connected to the same combined with means to turn said screws together to move the said wheels simultaneously in opposite vertical directions, whereby the thresher is maintained in a vertical position while working on a hillside.
3. In a traveling harvester and in combination with a threshing-machine frame thereof, bearing-wheels upon opposite sides of said frame having independent shaft and journal boxes therefor, guides in which said journal-boxes are movable up or down with relation to the ground, vertical screw-shafts connecting with the wheel-boxes, mechanism by which the journal-boxes of one wheel are moved in the opposite direction to and in unison with those of the other wheel and mechanism for reversing said movement.

On the issue of this interference priority of invention was awarded to Haines, the senior party to the interference proceeding

Funk being the junior party, the *onus* of proof is upon him to establish priority of invention by clear and distinct proof.

The case is one principally of fact; but upon the application of facts, a few well-settled principles of law must be kept in view.

According to well-settled principles, Haines, being the senior party, the first to apply to the Patent Office, has, *prima facie*, the priority of right, and the *onus* of proof is upon any junior applicant to show, not only priority of invention, but he must also show that he has used reasonable diligence in adapting and perfecting his invention; for, in such case, the mere conception without actual reduction to practice within a reasonable time, does not avail a junior party making the claims. This principle is settled by many decisions, both of the Patent Office and of this court. It is also a settled principle in patent law, that whoever first perfects a machine is entitled to the patent therefor, and is the real inventor, although others may have previously had the idea and made some experiments toward putting it in practice; subject, however, to this qualification, that if the party who first conceives the invention was, at the time of a second invention by another party, using reasonable diligence in perfecting the same, he is entitled to be recognized as the first inventor, although the second to conceive may have been the first to reduce to practice, either actual or constructive. (*Agawam Co.* v. *Jordan*, 7 Wall., 583.) In order to constitute a patentable invention, there must be more than mere progress to an end, however near that progress may have approximated to the end in view. The law requires, not conjecture, but certainty; and where, as in the present case, the question relates to a machine, the conception must have been clothed in substantial form, which demonstrates at once its practical efficiency and utility. (*Coffin* v. *Ogden*, 18 Wall., 120.)

In the production of proof, in matters of interference, the parties must be held strictly to the dates set forth in their preliminary statements. In the preliminary statement filed by Funk, which is made under oath, he states that he conceived the invention contained in claims 9, 10 and 11, of his application, declared to be involved in this interference, on or about the 15th day of August, 1893, as near as he could fix the time; that he first made a sketch, illustrating the invention, on or about the 12th day of May, 1898; that he first disclosed the invention to another person on or about the 2d day of April, 1898, as near as he could recollect; that he never made any small-sized model embodying the invention; but that the construction of a full-sized, operative device, embodying said invention, was commenced on or about the 1st of January, 1899, and was completed on or about the 20th of March, 1899, and was put into practical and successful operation during the harvest of 1899, and was manufactured for sale and commercial use.

The subject-matter of the interference is a device for harvesting standing grain on hillsides or unlevel ground, and is designed to be used in combination with a preëxisting machine for cutting, threshing, and winnowing grain, and transferring it from one part of the machine to another. The parties to this interference do not profess or claim to be the pioneers or first inventors of the means for this particular purpose, but they all appear to have been, as shown by the facts and found by the Examiner of Interferences, well acquainted with the invention of Benjamin Holt at the time of their first efforts at improvement. As found and stated by the Examiner of Interferences, Funk was an operator of a harvester containing the Holt invention, and which he attempted to improve. Matteson and Haines were independent manufacturers in the same town in which the Holt people carried on the manufacture of harvesters; and they directed their efforts to getting something in the way of improvement, but, in so doing, they desired to avoid infringement of the Holt patent. The Matteson & Williams Manufacturing Company, with which Matteson was connected, went into insolvency before Matteson filed his application, and was then put into the hands of trustees for the creditors. Among the principal creditors were the Holt concern. About the time this interference was originally declared the Holt concern absorbed the Houser-Haines Company, so that the Holt concern are real parties in interest in this proceeding as against Funk. The Examiner of Interferences then states the case of Funk, as shown by the facts, and says that it consists of his, Funk's, unsupported allegation of conception of the matter in issue, in the fall of 1895, while operating the Holt machine, though he alleges in his preliminary statement that he conceived the invention in 1893; but he does not claim in his testimony, to have made any effort to reduce his invention to practice at that time, nor for a considerable time there after. In the winter or spring of 1898, he worked with J. L. Hughes, an agent of the Houser-Haines Company, helping him to make some models of devices gotten up by Hughes for accomplishing the same purpose as the device of the present interference. Sketches and models of these latter devices were sent to the Houser-Haines Company, but were discarded or abandoned, either because they were deemed worthless or that they might conflict with the Holt patent.

It was not until sometime in the latter part of April, 1898, that Funk disclosed his alleged invention of the matter in issue to Hughes, and to Severance, the village blacksmith, and a number of imperfect sketches were made about that time. Four sketches are in evidence as Funk's Exhibits 4, 5, 6 and 7, which are claimed to show the matter in issue. The Examiner of Interferences, in his opinion in the record, has reviewed the evidence in detail, and has stated the evidence as favorably to Funk as possible, and he came to the conclusion that Funk had proven conception, disclosure, and the making of sketches as early as the fore part of May, 1898, but did not reduce his conception to practice until he filed his application, June 12, 1900; and therefore, because of the want of reasonable diligence, or the failure to show a valid excuse for the long delay, he would necessarily fail in this interference, unless it could be found as a fact, that he had disclosed the matter in issue to Haines, the senior party, and the latter, by adopting and completing the invention, and reducing the same to actual practical operation, had thus entitled Funk to claim as his own the completed invention. And, upon review of the evidence bearing upon the fact of the alleged disclosure to Haines, by Hughes acting for Funk, the Examiner of Interferences thought he was justified in concluding that disclosure had been made to Haines, and that the latter had unjustifiably appropriated the invention as his own, and manufactured and tested the machine as early as October, 1898; and it was put upon the market and extensively used in the harvest of 1899. This conclusion was reached in opposition to the clear and positive denial of Haines, as to the alleged disclosure made to him, and in regard to which he is corroborated by two other unimpeached witnesses. The conclusion of the Examiner is based largely upon the testimony of Hughes; and the result was that priority of invention was awarded to Funk.

One of the witnesses produced by Haines was Martyn, who was in the employ of the Houser-Haines Company in the year 1898, as foreman of the construction of machines; and he testifies that about the latter part of April, 1898, as near as he can recollect, the company commenced figuring on a harvesting-machine, having screws by which the wheels were raised and lowered; that Haines first disclosed that construction to the witness, and how it was to be made and operated, one day, and the next day, he (the witness) made a sketch of it and showed it to Haines; that he made the drawings, Haines's Exhibits A and B, during the summer of

1898, to show the machine they were getting up, and which were afterward completed in accordance with these exhibits; that the machine was begun sometime during the month of June: that these Exhibits A and B disclosed every count of this issue.

This witness also testified that the machine was built in the summer of that year, 1898, and was tested in 1898, and operated in fieldwork in 1899, and that twenty-one machines of that kind were built and put into use in the year 1899. He also testified that he made the Exhibits A and B from sketches made by Haines.

The witness Kincaid also testified to facts strongly corroborative of the testimony of Haines.

From the award of priority to Funk by the Examiner of Interferences appeals were taken to the Board of Examiners-in-Chief, by both Haines and Matteson. And, upon very full and careful review and analysis of the evidence, that tribunal reversed the award of the Examiner of Interferences, and adjudged priority of invention in favor of Haines. From this determination both Funk and Matteson appealed to the Commissioner of Patents, and these last appeals were heard and decided by Acting Commissioner Moore. The Acting Commissioner went carefully and fully over the evidence, and his conclusion was in affirmance of the findings and judgment of the Examiners-in-Chief. It is from this latter decision that Funk has appealed to this court.

Both the Examiners-in-Chief and the Acting Commissioner, upon careful analysis of the evidence, concluded that Funk in fact had never made or operated any machine containing the invention of the issue of this interference. That the allegations of Funk, in his preliminary statement, to the effect that he had invented, made, and operated the machine within the description of the present interference are founded wholly upon his contention that he first conceived the invention, and that his conception was disclosed to Haines, and that the actual reduction to practice of the invention by Haines was only the practice of his, Funk's, invention, and that he, Funk, is entitled to it as the production of his invention. But the Examiners-in-Chief and the Acting Commissioner conclude otherwise, and in their conclusion, upon careful examination of the evidence, we entirely concur. They find and conclude from the evidence, that all that Funk ever did toward making and completing the invention in issue, was the making a pencil sketch, and the causing other pencil sketches to be made, and the delivery of two of those sketches to his witness Hughes. That there was no evidence to establish the fact, other than the testimony of Funk himself, that he ever had any possession of the invention here at issue prior to the year 1898. And if we assume the truth of the statement contained in the preliminary statement of Funk, or even that contained in his testimony, as to the time of conception of the invention, the great delay in attempting to complete and reduce the invention to practical operation, is entirely without explanation, and must, consequently, give rise to a strong presumption against his pretension.

As very properly said by the Acting Commissioner, Haines being the first to reduce to practice, and first to apply to the Office, must be presumed to be an original inventor of the machine, which, it is conceded, he built and operated, and for which he was first to make an application for a patent. Funk controverts this right of Haines, and it is incumbent upon him to show, by clear and indubitable proof, that the presumption in favor of Haines is not well founded, and that the right is in himself, as against both Haines and Matteson. Such proof he has failed to produce.

Upon the record before us, and in view of the legal principles applicable to the case, and to which we have referred, we hold that the decision appealed from is correct, and must therefore be affirmed. The proceeding of this court and this opinion will be certified to the Commissioner of Patents, as directed by the statute. Decision affirmed.

Court of Appeals of the District of Columbia.

FUNK *v.* HAINES.

Decided June 25, 1902.

INTERFERENCE—PRIORITY—DECISION AFFIRMED.

As the parties to this interference are also parties to the pending interference, No. 20,436, and as this case depends in all respects upon the same facts and the evidence is the same, *Held* that for the reasons in that case assigned H. is the prior inventor.

Messrs. Munn & Co. for the appellant.

Mr. T. Walter Fowler for the appellee.

ALVEY, *C. J.:*

This is an appeal from the Patent Office in matter of interference between an application of Funk filed June 12, 1900, and an application by Haines, filed December 29, 1898. The applications relate to harvesters, and the interference is No. 20,670, and is a companion case to No. 20,436, which has just been decided by this court.

There is but a single issue, and that is defined as follows:

In a traveling harvester, a supporting-frame, upper and lower boxes, the upper boxes being supported by the lower boxes, supporting-wheels journaled in the lower boxes, screw devices for raising and lowering the boxes, and means for reversely turning the screw devices belonging to the respective boxes of the supporting-wheels.

The parties to this interference are also parties to the preceding interference No. 20,436, which we have just decided. The evidence in both cases is the same, and the issues differ only in including the upper boxes for the ruts. The cases were argued together, and treated as substantially one case.

We have held in the preceding case, No. 20,436 affirming the decision of the Acting Commissioner of Patents, that Haines is entitled to priority of invention. And as this case depends, in all respects, upon the same facts as the preceding case, we must, for the reasons in that case assigned, hold in this case likewise that Haines is entitled to priority of invention, and therefore affirm the decision appealed from by Funk. The proceeding in this court and the decision here made will be certified as directed by the statute. Decision affirmed.

Patents Nos. 707,531 to 707,999.

Preparation of Specifications, Entry of Amendments, Etc.

LEGIBLE WRITING REQUIRED.

The specification and claims must be plainly written or printed on but one side of the paper. All interlineations and erasures must be clearly referred to in marginal or foot notes on the same sheet of paper. Legal-cap paper with the lines numbered is deemed preferable, and a wide margin must always be reserved upon the left-hand side of the page.

AMENDMENTS MUST BE SPECIFIC—HOW WRITTEN.

In every amendment the exact word or words to be stricken out or inserted in the application must be specified, and the precise point indicated where the erasure or insertion is to be made. All such amendments must be on sheets of paper separate from the papers previously filed, and written on but one side of the paper. Erasures, additions, insertions, or mutilations of the papers and records must not be made by the applicant.

SPECIFICATIONS REWRITTEN.

When an amendatory clause is amended, it must be wholly rewritten, so that no interlineation or erasure shall appear in the clause, as finally amended, when the application is passed to issue. If the number or nature of the amendments shall render it otherwise difficult to consider the case, or to arrange the papers for printing or copying, the Examiner or Commissioner may require the entire specification to be rewritten.

Classification Bulletin.

CLASSIFICATION BULLETIN No. 7, containing the revision made during the months of May and June, 1902, has been published. Price, ten cents.

APPLICATIONS UNDER EXAMINATION.

Condition at Close of Business August 19, 1902.

Room No.	Divisions and subjects of invention.	Oldest new application and oldest action by applicant awaiting office action. New.	Amended.	No. of applications awaiting action.
	In arrears—Under one month.			
253	X. Carriages and Wagons	Aug. 9	Aug. 9	50
217	XXXIII. *Designs, †Trade-Marks, ‡Labels and Prints, Optics, and Photography.	Aug. 2	Aug. 2	55

Punctuation and Amendments.

Attention is called to Order 789, dated November 26, 1892, which is as follows:

It is hereby directed that in the printing of claims of applications for patents the punctuation of the claims as made by applicants be strictly followed, and that the punctuation of the specification made by applicants be not departed from except to cure a manifest absurdity.

This order is still in force.

Examiners are prohibited from making any change in the claims or specification of an application without the consent of applicants or their attorneys; but when amendment becomes necessary the Office will duly advise, by letter, the applicant or his representative before passing a case to issue.

Women Inventors.

The Patent Office has published and has for sale a volume containing a list of women inventors to whom patents have been granted by the United States from 1790 to July 1, 1888. 44 pages. Paper covers, 50 cents.

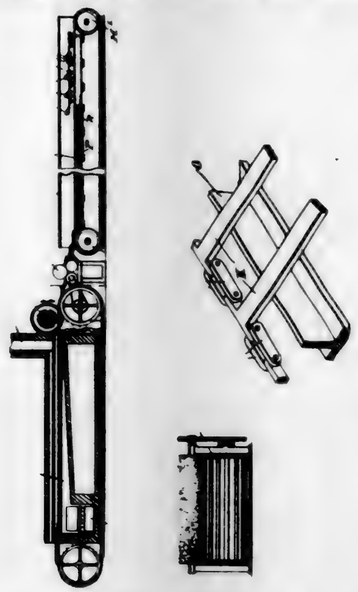
An Appendix to the above, covering the period from July 1, 1888, to October 1, 1892. One volume, 18 pages. Paper covers, 25 cents.

Appendix No. 2, October 1, 1892, to March 1, 1895. One volume, 98 pages. Paper covers, 25 cents.

PATENTS

GRANTED AUGUST 26, 1902.

707,581. APPARATUS FOR SEPARATING THE PITH OR CORE FROM THE RIND PORTION OF FIBROUS MATERIAL. ANDREW J. ADAMSON, Chicago, Ill., assignor, by direct and mesne assignments, to the Adamson Manufacturing Company, Chicago, Ill., a Corporation of West Virginia. Filed July 19, 1901. Serial No. 68,906. (No model.)



Claim.—1. In an apparatus for separating the pith or core from fibrous or other material, the combination of roasting, compressing, drying and beating apparatus, arranged and operating in the manner and for the purpose set forth.

2. In an apparatus of the class described, a roasting-furnace, means for feeding the material to be roasted therethrough, a compressing apparatus to which said feeding means delivers the roasted material, a drier arranged to receive the compressed material from said compressing mechanism, and beaters operating to separate the pith or core from the rind portion of the material treated, as and for the purpose set forth.

3. In an apparatus of the class described, a roasting-furnace provided with a chamber extending therethrough, a carrier operating through said chamber, a compressing mechanism to which said carrier delivers, a drying-chamber, a carrier operating therethrough and arranged to receive the material from the compressing apparatus, and beaters arranged to complete the separation of the pith or core from the rind portion of the material treated, all combined and arranged as and for the purpose set forth.

4. In an apparatus of the class described and in combination with roasting and compressing mechanisms, of a drier comprising a chamber, a carrier operating through said chamber, means for heating said chamber, shafts transversely journaled in said chamber and provided with beaters, and means for rocking said shafts, as and for the purpose set forth.

5. In an apparatus of the class described and in combination with roasting and compressing mechanism, of a drier, a carrier operating through said drier, shafts journaled above said carrier and having arms, transverse slats carried by said arms, and means for rocking said shafts whereby said slats exert a beating effect over said carrier, as and for the purpose set forth.

6. In an apparatus of the class described and in combination with roasting and compressing mechanism, of a drier, a carrier operating therethrough, shafts transversely mounted in said drier and carrying arms, slats connecting the arms of each shaft, said slats extending transversely of the carrier and above the same, crank-arms carried by said shafts, cams arranged to rock said arms, means for actuating said cams, and means for opposing the action of said cams, as and for the purpose set forth.

7. In an apparatus of the class described and in combination with roasting and compressing apparatus, of a drier, supports extending longitudinally therethrough, a carrier operating upon said supports and comprising transverse slats connected at their ends by links, heating-coils arranged beneath the path of travel of said carrier and adjacent thereto, and beaters operating over the upper surface of said carrier adjacent to the rear end thereof to pound or beat the material conveyed by said carrier, as and for the purpose set forth.

8. In an apparatus of the class described, a furnace, a carrier operating therethrough, a compressing mechanism to which said carrier delivers, and a scraping device interposed between the furnace and compressing mechanism and operating to remove any charred or burned fragment from the material operated on, as and for the purpose set forth.

9. In an apparatus of the class described, a furnace, a carrier operating therethrough and a compressing mechanism to which said carrier delivers, in combination with a drum-brush arranged transversely across and above said carrier and between said furnace and compressing mechanism, as and for the purpose set forth.

10. In an apparatus of the class described, a furnace, a carrier operating therethrough, a compressing mechanism to which said carrier delivers, in combination with a rotary brush arranged transversely across the path of travel of said carrier and above the same, said brush adapted to be rotated in the direction of travel of the carrier but at a higher rate of speed, as and for the purpose set forth.

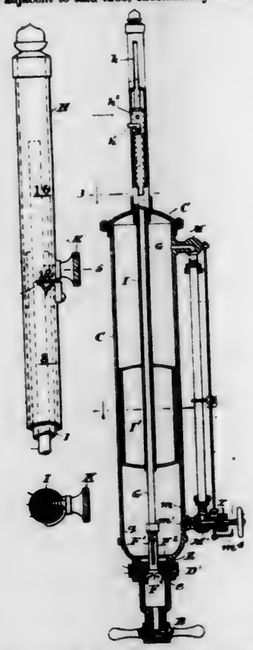
707,582. MEASURING-FAUCET AND AUTOMATIC GRADUATE. GEORGE J. ADAMS, Brooklyn, N. Y. Filed Aug. 24, 1899. Serial No. 728,271. (No model.)

Claim.—1. In combination, the two-way faucet, a measuring vessel connected therewith, a valve controlling the passage of liquid from the faucet to the vessel, a slotted tubular extension above said vessel, a stem or rod extending upward from the valve through said vessel and into said tubular extension, a float within the vessel having an extension also extending into said tubular extension, means for adjustably securing said stem and float extension together, and a pointer connected with the float extension and coacting with a scale on the tubular extension, substantially as described.

2. In combination the two-way faucet, the measuring vessel connected therewith, the valve-chamber between said vessel and faucet, the valve in said chamber having an extension, the rod having a limited sliding connection with said extension, said rod extending up through the measuring vessel, the float within the vessel having an extension extending up in proximity to the said rod, and means for adjustably securing said rod and float extension together, substantially as described.

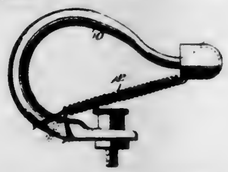
3. In combination the two-way faucet, the valve-chamber detachably connected thereto, the measuring vessel detachably connected with said valve-chamber, the valve located in said chamber and having a tubular extension extending up into said vessel, the tubular extension above said measuring vessel, the rod having its lower end seated in the valve extension and having a limited sliding movement therein, the upper end of said rod extending into the extension of the vessel, the float within the vessel having a tubular sleeve or extension extending upward above the vessel, and the set-screw passing through a slot in the extension of the vessel and adjustably securing said sleeve and rod together, substantially as described.

4. In combination, the two-way faucet, a measuring vessel connected therewith, a valve to close the opening to said vessel, a float connected with said valve, a tube arranged parallel to the vessel and connected therewith at top and bottom, said bottom connection including a plunger-chamber, a plunger working in said plunger-chamber, and an adjustable indicator adjacent to said tube, substantially as described.



5. In combination with the faucet having a two-way valve or plug, a measuring vessel connected therewith, a valve, interposed between said vessel and faucet, a float controlling said valve, a hollow extension M at the lower part of said vessel and communicating with the interior thereof, a glass tube arranged parallel with the cylinder and having its lower end communicating with the interior of said extension and its upper end in communication with the upper portion of the vessel, and a displacement-plunger located in said extension, substantially as described.

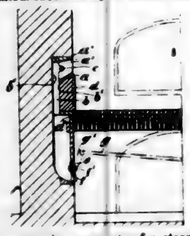
707,583. CHECK-HOOK KEEPER. THOMAS ALBEE, Hallstead, Pa. Filed Apr. 1, 1902. Serial No. 100,978. (No model.)



Claim.—As a new article of manufacture, a checkrein-hook attachment consisting of a spring having a cap at one end adapted to engage the free end of the checkrein-hook and with two normally distended loops upon the other end adapted to engage the shank of the hook and exert a gripping force thereon, substantially as described.

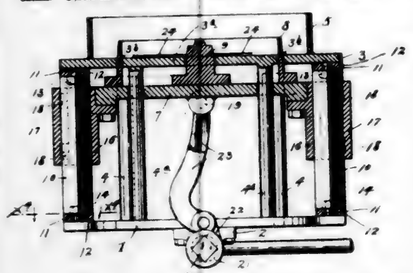
707,584. SMOKE-CONSUMING APPLIANCE FOR FURNACES. JOHN ALVIN, London, England. Filed Feb. 11, 1901. Serial No. 46,688. (No model.)

Claim.—1. In a steam-boiler or other furnace, a fire-chamber, a rabbet or recess in each side wall of the said chamber and extending above and below the fire-bars, a longitudinal casting set in each said recess, vertical slots in the upper part or bar of the said casting whereof the sides converge from the bottom to the top and the upper and lower ends incline upward, a steam-jet pipe traversing the recess behind the slots, openings in the lower part of the said casting and dampers in said openings whereby the admission of air to the recess or chamber behind the casting is regulated, substantially as herein described.



2. In smoke-consuming apparatus for steam-boiler and other furnaces, the combination with the dampers *f f* of the trunnions *f' f'*, lever *f''* at the front of the furnace, connecting-rod *g* and levers *g'* substantially as and for the purposes specified.

707,585. MOLDING-MACHINE. JAMES F. APPLEBY, Hopkins, Minn. Filed Mar. 31, 1902. Serial No. 100,886. (No model.)

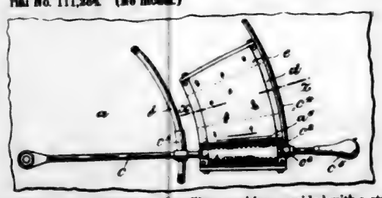


Claim.—1. In a molding-machine, the combination with a frame including a stripper-plate, of vertical guide-posts mounted on said frame with freedom for universal adjustments in a horizontal plane, a pattern-plate guided by said adjustable guide-posts, and means for imparting vertical movements to said pattern-plate, substantially as and for the purposes set forth.

2. In a molding-machine, the combination with a frame including a stripper-plate rigidly supported therefrom, of vertical guide-posts provided with trunnions at their ends, anchoring-brackets having seats closely fitting said trunnions, and screws for securing said brackets to said frame, which screws work through relatively large holes in said brackets, whereby said brackets are made adjustable, substantially as described.

3. In a molding-machine, the combination with a frame including a stripper-plate 3, of the square guide-posts 10 having the trunnions 11, the brackets 12 having seats closely fitting said trunnions, the machine-screws 13 and 14 working through the relatively large perforations 15, in the upper brackets 12 and adjustably securing the same, and the vertically-movable pattern-plate provided with keeper-brackets working on said guide-posts 10, substantially as described.

707,586. CIGAR-BUNCH-ROLLING MACHINE. GEORGE W. ARNOLD and WILLIAM M. CRANSTON, Philadelphia, Pa., assignors of one-third to Joseph E. Lutz, Philadelphia, Pa. Filed June 12, 1902. Serial No. 111,284. (No model.)

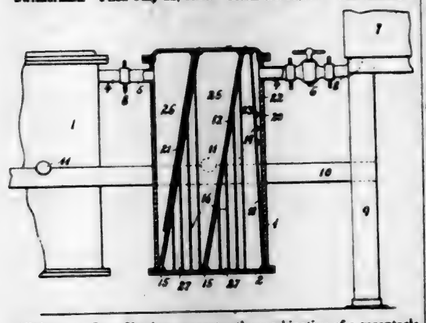


Claim.—1. A cigar-bunch-rolling machine provided with a stationary bed having a recess and a substantially semicylindrical depression, a series of springs supported in vertical position from said bed, a sheet supported by said springs and secured to said bed and forming a spring balanced or cushioned table, an apron secured by its ends to said table, and means for manipulating said apron on said sheet within said depression and over other portions to bunch and roll a filler material, substantially as and for the purposes described.

2. A cigar-bunch-rolling machine provided with a stationary bed having a recess and a substantially semicylindrical depression, and legs in which are mounted helical or coiled springs, a metal sheet spanning the recess and depression of said bed and supported under uniform tension by said springs, an apron secured at both ends to said bed and a roller for manipulating said apron on the sheet within the depression of said bed and over other portions of said table, substantially as and for the purposes described.

3. A cigar-bunch-rolling machine provided with a stationary bed having a depression, a series of springs projecting from said bed, a thin metal sheet secured to said bed and supported by said springs in position under uniform tension, an apron secured at both ends to said bed, and a traveler-roller adapted to roll a mass of filler material in said depression under spring tension into a uniform or even bunch, substantially as and for the purposes described.

707,587. FILTERING APPARATUS. CARL BARCHLER, Zurich, Switzerland. Filed July 22, 1901. Serial No. 69,297. (No model.)



Claim.—1. In a filtering apparatus the combination of a receptacle containing an inlet and outlet, with filter-screens dividing said receptacle into compartments, upright slabs forming narrow openings with said filter-screens, a partition containing openings, said openings having hoods directly above them, and means for connecting said apparatus to a pouring-basin, substantially as described.

2. In a filtering apparatus the combination of a receptacle containing an inlet and an outlet, said receptacle being pivotally mounted on rails attached to upright, with a filter screen or screens dividing said receptacle into compartments, upright slabs, a partition containing triangular holes, said holes having triangular hoods above them and a shield for forcing a downward flow of the fluid, substantially as described.

707,588. RIM AND FELLY FOR RUBBER VEHICLE-TIRES. JOHN BAKER, Meacham, Ill. Filed Apr. 9, 1902. Serial No. 102,023. (No model.)

Claim.—1. The combination with a tire having in part a smaller diameter than the rim to receive the same, of a laterally-split rim provided on both its side edges with devices adapted to receive and retain a rubber tire in place thereon and provided with a beveled inner face, said rim being adapted to be contracted to enter the tire and expanded to receive the latter, and a felly having a beveled outer face adapted to receive and expand said rim and hold same in its expanded position.

2. The combination with a pneumatic tire having an inflating-valve projecting therefrom, of a rim having an opening to receive said valve, said rim being split at a point diametrically opposite said opening and adapted to be contracted to enter the tire and expanded to receive and hold the latter, and a felly having an opening to receive said valve, said rim and felly being partially beveled on their contact-surfaces opposite said openings.

3. The combination with a tire having in part a smaller diameter than the rim to receive the same, of a laterally-split rim provided on both its side edges with devices adapted to receive and retain a rubber tire in place thereon and provided with a beveled inner face, said rim being adapted to be contracted to enter the tire and expanded to receive the latter, openings in the inner face of said rim adjacent one edge thereof, adapted to receive expanding devices, and a felly having a beveled periphery adapted to receive said rim, said rim being adapted to be partially inserted into position on said felly while the expanding devices are held in place thereon and subsequently, after removal of said expanding devices, forced into proper position on said felly and completely expanded by the latter.

4. The combination with an endless tire, of a split rim adapted to be contracted to enter said tire and expanded to receive and hold the latter, the joint in said rim being on a bevel and having a tongue and groove interfitting with each other to prevent relative lateral movement of those parts of said rim on each side of said joint, and a felly adapted to receive said rim and hold same in its expanded position.

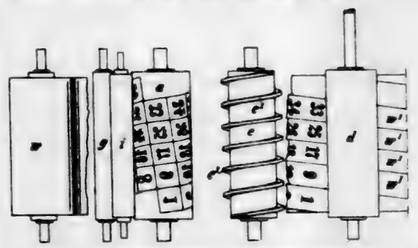
707,589. DRAFT-EQUALIZER. THOMAS W. BARTA, New Richmond, Ind. Filed Dec. 23, 1901. Serial No. 87,557. (No model.)

Claim.—1. The combination with the plow-beams and cross-clevis, a draft-clevis attached to the end of said cross-clevis, a spring-bar connected to the end of said plow beam around the end of cross-clevis and the yielding connection between the side draft-clevis and the end of spring-bar, substantially as set forth.

2. The combination with the plow-beams and cross-clevis, one end of said cross-clevis projecting laterally beyond the plow-beam, of a draft-clevis attached to the projecting end of the cross-clevis, a spring-bar connected to the opposite end of said plow-beam A', a yielding connection between the said spring-bar and draft-clevis, said yielding connection comprising a twisted link, a folded strap or bar, a longitudinally-slotted plate, and an angular plate having a hook at one end, substantially as described.

3. In a device of the kind described, the combination with the angular plate having a hook at one end, the longitudinally-slotted bar or plate connected to said link, the folded strap having a bolt passing through its ends and also through the slotted plate or bar, the twisted link and the spring-bar having an eye or loop at one end adapted for engagement with the twisted link, substantially as set forth.

707,540. PRINTING-PRESS. ALPHONS BARDES, Hamburg, Germany. Filed Aug. 10, 1901. Serial No. 71,641. (No model.)



Claim.—1. In a printing-press, a printing-surface containing columns of symbols set at an angle to the length of the material to be printed upon and arranged to successively print said column of symbols, the bottom of one column to register with the top of another column, whereby a plurality of columns of symbols will be successively printed in alinement, and means for feeding the material, substantially as and for the purpose set forth.

2. In a printing-press, a printing-surface containing parallel columns of symbols set at an angle to the length of the material to be printed upon and to register the foot of a column with the top of the next adjacent column, whereby the columns of symbols will be successively printed in

alinement, and means to feed the material, substantially as and for the purpose set forth.

3. In a printing-press, a printing-cylinder, columns of symbols thereon spirally arranged and the symbols arranged at an angle to the elements of said cylinder to simultaneously print all the columns of symbols and cause the bottom of one column to register with the top of an adjacent one, whereby the columns of symbols will be successively printed in alinement, an impression-cylinder and means to feed the material to be printed upon, substantially as and for the purpose set forth.

4. In a printing-press, a printing-cylinder, parallel columns of symbols arranged spirally thereon to print diagonal columns of symbols and to cause the bottom of one column to register with the top of the next adjacent column in the next succeeding impression, whereby the columns of symbols will be successively printed in alinement, an impression-cylinder and means to feed a continuous web, substantially as and for the purpose set forth.

5. In a printing-press, a printing-cylinder, parallel columns of symbols arranged spirally thereon to print diagonal columns of symbols and to cause the bottom of one column to register with the top of the next adjacent one, whereby the columns of symbols will be successively printed in alinement, an impression-cylinder, means to feed a continuous web and means to cut the columns of symbols into diagonal strips, substantially as and for the purpose set forth.

6. In a printing-press, a printing-cylinder, parallel columns of symbols arranged spirally thereon to print diagonal columns of symbols and to cause the bottom of one column to register with the top of the next adjacent one, an impression-cylinder, means to feed a continuous web and a spiral cutter having the same pitch as the symbols on the printing-cylinder to cut the web into diagonal strips, substantially as and for the purpose set forth.

7. In a printing-press, a printing-cylinder, parallel columns of symbols arranged spirally thereon to print diagonal columns of symbols and to cause the bottom of a column to register with the top of the next adjacent column, an impression-cylinder, means to feed a continuous web and coöperating spiral cutters having the same pitch as the columns of symbols on the impression-cylinder, one above and the other below the continuous web to cut said web into columns of symbols diagonally and between the columns, substantially as and for the purpose set forth.

707,541. METHOD OF PRODUCING PRINTED MATTER. ALFONS RABDOR, Hamburg, Germany. Original application filed Aug. 10 1901, Serial No. 71,641. Divided and this application filed Dec. 18, 1901. Serial No. 86,381. (No specimens.)

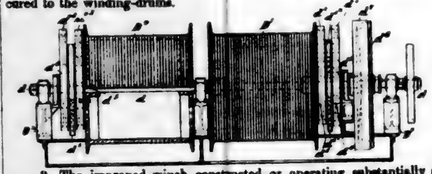
Claim.—1. The method of printing continuous strips, which consists in arranging the printing-surfaces in rows at such an angle to the length of the material to be printed upon, that the end or foot of each row will register with the top or beginning of the next adjacent row at the next succeeding impression, and taking successive impressions from the printing-surface to produce columns of printed matter longer than a row of printing-surfaces, substantially as described.

2. The method of printing symbols in continuous strips, which consists in arranging the printing-surfaces in parallel rows at such an angle to the length of the material to be printed upon, that the foot or bottom of each parallel row will register with the top of the next adjacent row when the material is moved lengthwise an amount equal to the length of the impression, and separating said material between the continuous rows of symbols into strips, substantially as and for the purpose set forth.

3. The method of printing continuous strips, which consists in arranging the printing-surfaces in parallel rows at such an angle to the length of the material to be printed upon, that the foot or bottom of each parallel row will register with the top of the next adjacent row, simultaneously taking an impression from all the rows, moving the material lengthwise the distance of a printed row preparatory to taking the next impression and cutting the material into strips between the diagonal continuous rows of impressions thus made, substantially as and for the purpose set forth.

707,542. MEANS FOR RAISING OR LOWERING MATERIALS. HERBERT A. L. BARRY, Westminster, England. Original application filed May 7, 1900, Serial No. 15,797. Divided and this application filed Nov. 30, 1900. Serial No. 38,284. (No model.)

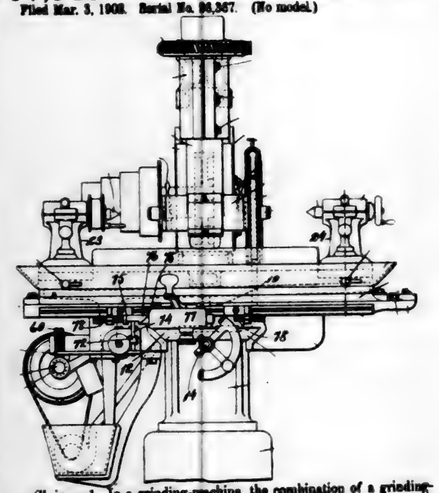
Claim.—1. The improved winch constructed or operating substantially as herein described and comprising a shaft, two drums arranged axially but loosely thereon, two carriers, the one fast and the other loose on the said shaft, one or pairs of epicyclic toothed pinions mounted on each carrier, two stationary toothed wheels and a toothed wheel secured to each winding-drum; one wheel of each pair of toothed pinions meshing with one of the stationary toothed wheels and the other wheel of each pair of toothed pinions meshing with one of the toothed wheels respectively secured to the winding-drums.



2. The improved winch constructed or operating substantially as herein described and comprising a shaft, a drum on said shaft, a carrier keyed to a sleeve in which the shaft rotates, two sets of epicyclic toothed pinions mounted on said carrier, a stationary toothed wheel wherewith one set of toothed pinions meshes, a toothed wheel secured to the winding-drum wherewith the other set of toothed pinions meshes, a friction-clutch whereof one part is keyed on the sleeve while the other or movable part is carried by the shaft and means for operating the said clutch.

3. In apparatus for raising and lowering materials, the combination with the framing of the drums D^9, D', carriers d', $d'^{\times}$, epicyclic pinions d^2, d^3 on said carriers, central toothed wheels d^4, d^5 respectively carried by the framing and the drums and meshing with the epicyclic pinions mounted on each side of the respective carriers, sleeve d^6, clutch d^7 d^8 and means for operating the clutch, substantially as set forth.

707,543. GRINDING-MACHINE. JOHN BATH, Waltham, Mass. Filed Mar. 3, 1900. Serial No. 96,367. (No model.)



Claim.—1. In a grinding-machine, the combination of a grinding-wheel arbor, a bearing therefor formed with a sliding bearing-face laterally opposite the arbor, a complemental fixed bearing face or guide, provisions for clamping said arbor-bearing to the guide on any point along the latter, a sliding stem or post connected with said arbor-bearing, a fixed guide or bearing for said post, and mechanism for imparting a longitudinal movement to said post.

2. In a grinding-machine, the combination of a guide for a grinding-wheel-arbor bearing, a support mounted for an angular or swinging adjustment about an axis parallel to said guide, heads provided with means for holding the work and mounted on said support with the line of centers of said means in a plane at right angles to the axis of movement of said support, a grinding-wheel arbor, a bearing therefor mounted to slide on said guide and capable of movement which carries said arbor across said plane, mechanism for imparting a longitudinal movement to said bearing along its guide, and provisions for clamping said bearing to the guide at any point along the latter.

3. In a grinding-machine, the combination of a grinding-wheel arbor, a bearing therefor, a stem or post connected with said bearing and formed with a screw-thread, a rotatable cap-and-nut member comprising a nut engaged with said thread and a cap covering the end of the post, and means for preventing axial movement of said nut.

4. In a grinding-machine, the combination of a grinding-wheel arbor, a bearing therefor, a stem or post connected with said bearing and formed with a screw-thread, a rotatable cap-and-nut member comprising a nut engaged with said thread and a cap covering the end of the post, a bearing engaged with said member on the end thereof nearest the arbor-bearing, and a second bearing engaged with the opposite end of the cap-and-nut member, said bearings preventing axial movement of the member.

5. In a grinding-machine, the combination of a C-shaped frame formed with a substantially flat tool-clamping rest on one arm of the C, a post guide or bearing on the opposite arm of the C, a post mounted to slide in said bearing and having an arbor-bearing located in the gap of the C, a grinding-wheel arbor mounted in said bearing, and a work-support mounted opposite the gap of the C.

6. In a grinding-machine, the combination of a C-shaped frame having a lower part provided with an upper clamping-face the forward part of which forms an exposed tool-clamping rest, an upper part detachably clamped to the rear part of said clamping-face, a grinding-wheel arbor, and a bearing therefor slidingly mounted on the upper part of said frame.

7. In a grinding-machine, a feed-carriage, opposite driving members connectible alternately with the carriage, carriage-actuated means adapted to connect and disconnect said carriage with the members and having a neutral or carriage-stopping position, and mechanism embracing the range of said means and having provisions for neutralizing said means in any part of its said range.

8. In a grinding-machine, a feed-carriage, opposite driving members connectible alternately with the carriage, carriage-actuated means adapted to connect and disconnect said carriage with the members and having a neutral or carriage-stopping position, said means including a reciprocating member, and a neutralizing lever, one of the last said two parts being formed with oppositely-acting cam-faces arranged to coact with the other part in any portion of the range of said reciprocating member, whereby to neutralize the said carriage-actuated means.

9. In a grinding-machine, the combination of a grinding-wheel arbor having a belt-pulley, a vertically-movable bearing carrying said arbor, a driving belt-pulley stationarily journaled, a substantially horizontal belt connecting said pulleys, a support having a vertical guide, a holder mounted to slide thereon, a belt-tightener mounted in said holder, and means for clamping said holder at any point along said guide.

10. In a grinding-machine, the combination of a support, a table pivoted thereon, work-holding means mounted on said table, stop-abutments on said table, relatively stationary oppositely-acting stop-screws coacting with said stop-abutments, and frictional clamping devices for securing said screws at any adjustment.

11. In a grinding-machine, the combination of a split clamping-sleeve having free lips, a stem screwing in one of said lips and having outer and inner shoulders embracing the other lip, the last said lips having a screw-threaded socket, a bearing-sleeve for the stem complementally threaded and screwing in said socket, and an adjustable frictional holding device acting laterally against said threaded sleeve.

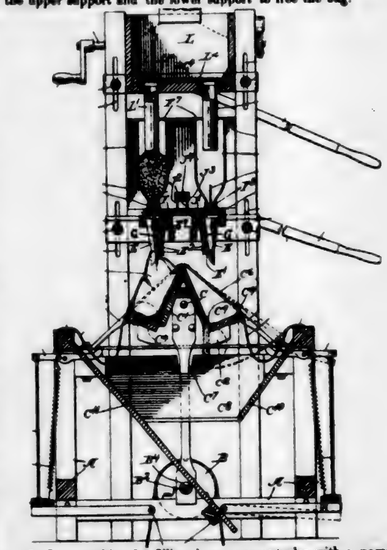
707,544. MACHINE FOR FILLING BAGS. ADELBERT M. BATES, Chicago, Ill. Filed Jan. 20, 1901. Serial No. 44,681. (No model.)

Claim.—1. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the material is introduced into the bag in a relatively small stream, with an upper support whereby the bag is secured at its upper end while open, a bottom-support whereby the bag is supported at its lower end, and means for positively moving and thus releasing both supports to free the bag.

2. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the material is introduced into the bag in a relatively small stream, with an upper support whereby the bag is secured at its upper end while open, a bottom-support whereby the bag is supported at its lower end, a vibrator of which the bottom-support forms part, and means for moving and thus releasing both supports to free the bag.

3. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the material is introduced into the bag in a relatively small stream, with an upper support whereby the bag is secured at its upper end, a bottom-support whereby the bag is supported at its lower end, and means for simultaneously or successively moving and thus releasing the supports to free the bag.

4. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the material is introduced into the bag in a relatively small stream, with a duplex upper support whereby the bag is secured at its upper end with a variable grip, a bottom-support whereby the bag is supported at its lower end, and means for positively moving and thus releasing the heavy grip of the upper support and the lower support to free the bag.



5. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the material is introduced into the bag in a relatively small stream, with a duplex upper support whereby the bag is secured at its upper end with a variable grip, a bottom-support whereby the bag is supported at its lower end, and means for positively moving and thus releasing the supports to free the bag and for successively releasing the two parts of the duplex upper support.

6. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance to be treated is fed into the bag in a relatively small stream, with bag-supports separated so as to leave the sides of the bag loose, the upper support adapted to hold the bag near one corner, the lower support adapted to receive one side and the bottom of the bag, mechanism for tilting the bottom-support to discharge the bag when it is full, and mechanism for vibrating such tilting bottom-support.

7. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance to be treated is fed into the bag in a relatively small stream, with bag-supports, the upper support adapted to hold the bag near one corner, the lower support adapted to receive one side and the bottom of the bag, and a mechanism for vibrating the bag and its lower support by a positive downward and upward motion in a line through the lower corner of the bag and at an angle to its length.

8. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance to be treated is fed into the bag in a relatively small stream, with bag-supports, the upper support adapted to hold the bag near one corner, the lower support adapted to receive one side and the bottom of the bag, mechanism for vibrating the bag and its lower support by a positive upward and downward motion in a line through the lower corner of the bag and at an angle to its length, the upper support comprising a clamping device which clamps the exterior of the bag to the filling-tube near the upper corner of the bag and above the discharge end of the filling-tube within the bag.

9. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism adapted to introduce the material in a relatively small stream into the bag, with a bottom-support for the bag, and a trip mechanism for such support whereby it may be removed to permit the bag to fall, an upper support whereby the upper part of the bag is retained in proper relation to its filling-tube, and a positive release mechanism to release the bag from its tube, said release mechanism being independent of the trip mechanism, so that the bag may be released at the top and its support removed from the bottom simultaneously or otherwise.

10. In a machine for filling bags or receptacles with a powdery or

granular substance, the combination of a bag-support with a feed mechanism comprising a relatively small tube-like part which leads from the supply to the bag, and an agitator within the passage from the supply to the bag, said agitator consisting of a long, thin, flexible wire, and means external to the tube for rapidly oscillating said wire so that by such oscillation and the flexibility of the wire it is kept in violent agitation and the contracted feeding-passage thus kept free.

11. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a bag-support with a feed mechanism comprising a relatively small tube-like part which leads from the supply to the bag, and an agitator within the passage from the supply to the bag, said agitator consisting of a long, thin, flexible wire, means external to the tube for rapidly oscillating said wire so that by such oscillation and the flexibility of the wire it is kept in violent agitation and the contracted feeding-passage thus kept free, said passage-way from the feed-supply to the bag being practically continuous, and the agitator projecting through the wall of said passage-way.

12. In a machine for filling bags or receptacles, the combination of a bag-support for holding the bag while it is being filled, a vibrating pitman to which it is secured and whereby it is supported directly above the pivot of such pitman, and a spring-support for the bag-support working outwardly in the direction of the length of the pitman, to keep the bag-support from being displaced.

13. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a filling-tube which introduces the substance into the bag, with an agitator therein, and means for rapidly moving said agitator within the tube to prevent the material from packing, said agitator consisting of a wire adapted to be rapidly oscillated, and a vibrator for the bag, and means connected with said wire and vibrator to keep both in operation simultaneously.

14. In a machine for filling receptacles, the combination of a supporting-frame with a supply-hopper-discharge portion vertically adjustable on the frame, a bag-supporting device on the frame, a series of devices for receiving the material from the hopper-discharging portion and conveying it to the bag, said series of devices vertically adjustable along the supporting-frame and containing parts which, with the discharge portion, form a measuring device adapted to be varied by the adjustment of the hopper-discharge portion with reference to the devices which receive the material from the hopper-discharge and convey it to the bag, and a windlass on the frame connected with the hopper-discharge portions so as to raise or lower the same.

15. In a machine for filling receptacles, the combination of a supporting-frame with a supply-hopper-discharging portion vertically adjustable on the frame, a bag-supporting device on the frame, a series of devices for receiving the material from the hopper-discharging portion and conveying it to the bag, said series of devices vertically adjustable along the supporting-frame and containing parts which, with the discharge portion, form a measuring device adapted to be varied by the adjustment of the hopper-discharge portion with reference to the devices which receive the material from the hopper-discharge and convey it to the bag, a windlass on the frame connected with the hopper-discharge portions so as to raise or lower the same, and means for attaching the devices which receive the material from the hopper-discharge portion and convey it to the bag to the hopper-discharge portion so that both can be moved simultaneously with the action of such windlass.

16. In a machine for filling receptacles, the combination of a receptacle-support with a receptacle-supplying passage-way, an agitator in the said passage-way to keep the material from packing, a driving mechanism, and connections from the receptacle-support and agitator to the driving mechanism, whereby the receptacle-support is rapidly vibrated and the agitator rapidly operated to keep the passage free and fill the receptacle.

17. In a machine for filling receptacles, the combination of a receptacle-support, having a hinged bottom, with a driving mechanism and a connection from the same to the support, whereby the latter is rapidly vibrated, a spring-support for the receptacle-support, and trip mechanism whereby the hinged bottom is operated to discharge the filled receptacle.

18. In a machine for filling receptacles, the combination of a series of filling tubes or funnels with a series of supply-sections associated therewith, there being twice as many filling tubes or funnels as supply-sections, and means for moving the supply-sections and funnels with reference to each other so that each supply-section is alternately placed in connection with one and then another of the filling tubes or funnels.

19. In a machine for filling receptacles, the combination of a series of filling tubes or funnels with a series of supply-sections associated therewith, there being twice as many filling tubes or funnels as supply-sections, and means for moving the supply-sections and funnels with reference to each other so that each supply-section is alternately placed in connection with one and then another of the filling tubes or funnels, the parts arranged so that the supply-section is closed at the bottom during the period intervening between its connection with one tube or funnel and the next.

20. In a machine for filling receptacles, the combination of a series of filling tubes or funnels with a series of supply-sections associated therewith, there being twice as many filling tubes or funnels as supply-sections, and means for moving the supply-sections and funnels with reference to each other so that each supply-section is alternately placed in connection with one and then another of the filling tubes or funnels, the parts arranged so that the supply-section is closed at the bottom during the period intervening between its connection with one tube or funnel and the next, and means for filling such supply-section when so closed.

21. In a machine for filling bags, the combination of a series of filling tubes or funnels, with a series of clamps adapted to clamp the bag against the side of such tube or funnel, and a cam device adapted to simultaneously release a series of such clamps.

22. In a machine for filling bags, the combination of a series of filling tubes of funnels, with a series of clamps adapted to clamp the bag against the side of such tube or funnel, and a cam device adapted to simultaneously release a series of such clamps, said tubes or funnels arranged in series, each series consisting of each alternate funnel, and said cam device adapted to release the clamps associated with each of said series alternately.

23. In a machine for filling bags, the combination of a series of filling tubes or funnels, with a series of weak clamps, one for each tube or funnel, and a series of strong clamps, one for each funnel, and a controlling device whereby the strong clamps are alternately thrown in and out of action in groups.

24. In a machine for filling bags, the combination of a series of filling tubes or funnels, with a series of clamps, and a longitudinal wavy cam device associated with said clamps, each successive swell of the cam being opposed to the second filling tube or funnel, and means for moving the filling tubes or funnels and cam device with reference one to the other, so that the clamps are operated to release or secure the bag in alternately-acting groups.

25. In a machine for filling valve bags or receptacles with a powdery or granular substance, the combination of a feed mechanism, comprising a feeding-tube, whereby the material is introduced into the bag, with an upper support for said bag forming part of the feeding-tube and comprising a part which bears against the inside of the bag near the top, and an outer part opposed thereto which bears against the outside of the bag near the top, said outer part adapted to clamp the material of the bag against the part within the bag and above the lower end of the feed-tube within the bag, a support for the bottom of the bag, a vibrator adapted to give the bag an up-and-down motion, the excursion of such vibrator related to the distance from the end of the feeding-tube to the point where the bag is clamped so that when the bag is nearly full the upper part of the bag about the feeding-tube will be free to have an accordion-like movement to prevent injury to the material of the bag.

26. In a machine for filling valve bags or receptacles with a powdery or granular substance, the combination of a feed mechanism comprising a feed-tube whereby the material is introduced into the bag, with an upper support for said bag forming part of the feeding-tube and comprising a part which bears against the inside of the bag near the top, and an outer part opposed thereto which bears against the outside of the bag near the top, said outer part adapted to clamp the material of the bag against the part within the bag and above the lower end of the feed-tube within the bag, a support for the bottom of the bag, a vibrator adapted to give the bag a laterally-vibratory motion, the excursion of such vibrator related to the distance from the end of the feeding-tube to the point where the bag is clamped so that when the bag is nearly full the upper part of the bag about the feeding-tube will be free to have an accordion-like movement to prevent injury to the material of the bag.

27. In a machine for filling valve bags or receptacles with a powdery or granular substance, the combination of a feed mechanism, comprising a feed-tube, whereby the material is introduced into the bag, with an upper support for said bag forming part of the feeding-tube and comprising a part which bears against the inside of the bag near the top, and an outer part opposed thereto which bears against the outside of the bag near the top, said outer part adapted to clamp the material of the bag against the part within the bag and above the lower end of the feed-tube within the bag, a support for the bottom of the bag, a vibrator adapted to give the bag an up-and-down and a laterally-vibratory motion, the excursion of such vibrator related to the distance from the end of the feeding-tube to the point where the bag is clamped so that when the bag is nearly full the upper part of the bag about the feeding-tube will be free to have an accordion-like movement to prevent injury to the material of the bag.

28. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance to be treated is fed into the bag in a relatively small stream,

with bag-supports adapted to support the bag so as to leave its sides relatively loose, and a vibrator comprising the bottom-support, a rod therefrom, and an eccentric whereby a rapid vibratory motion is imparted to the bag and contents, the rod being pivoted below on such eccentric and attached above to the bottom-support, and a spring device acting outwardly and in the line of the pitman away from its pivot and so as to hold the pitman in position.

29. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance is fed into the bag in a relatively small stream, with bag-supports adapted to support the bag so as to leave its sides relatively loose, and a vibrator which contains a spring member and which imparts a rapid laterally-vibratory motion to the bag and contents and thus breaks down the pyramid or column of material within the bag.

30. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance is fed into the bag in a stream much smaller than the cross-section of the bag, with bag-supports adapted to support the bag so as to leave its sides relatively loose during the process of filling, and a vibrator which contains a spring member and which imparts a rapid vertical motion to the bag and contents and thus breaks down the pyramid or column of material in the bag.

31. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance is fed into the bag in a relatively small stream, with bag-supports adapted to support the bag so as to leave its sides relatively loose, and a vibrator which contains a reciprocating and a spring member and which imparts a rapid combined vertical and lateral vibratory motion to the bag and contents and thus breaks down the pyramid or column within the bag.

32. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feeding mechanism whereby the substance is fed into the bag in a stream much smaller than the cross-section of the bag, with bag-supports adapted to support the bag so as to leave the sides relatively loose during the process of filling, and a vibrator which includes the bottom-support for the bag and a spring member, and which is adapted to impart a rapid motion to the bag and contents so as to break down the pyramid or column of material within the bag.

33. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism whereby the substance is fed into the bag in a stream much smaller than the cross-section of the bag, such mechanism containing a funnel or tube which projects down into the bag, with bag-supports to support the bag so as to leave its sides relatively loose during the process of filling, and a vibrator which contains a spring member and which has a rapid positive upward-and-downward motion aided by said spring member so as to impart a rapid motion to the bag and contents.

34. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism adapted to introduce the material into the bag in a relatively small stream, with a bottom-support for the bag and a top support for the bag, the two separated from each other so as to leave the sides of the bag loose, and non-automatic trip mechanism for the bottom-support whereby the latter may be removed at the will of the operator to permit the bag to fall when the operator so desires.

35. In a machine for filling bags or receptacles with a powdery or granular substance, the combination of a feed mechanism adapted to introduce the material into the bag in a relatively small stream, with a bottom-support for the bag, a vibrator of which the bottom-support forms part, and a trip mechanism for such vibrator-support whereby the latter may be removed to permit the bag to fall.

36. In a machine for filling bags or receptacles, the combination of a bag-filling device with means for supporting the top of the bag and a bag-support for the bottom of the bag and a spring-support on which the bag-support rests while the bag is being filled, and a vibrator to give such bottom-support a rapid vibratory motion while the bag is being filled.

37. In a machine for filling bags or receptacles, the combination of a bag-filling device with means for supporting the top of the bag and a bag-support for the bottom of the bag and a spring-support on which the bag-support rests while the bag is being filled, and a vibrator to give such bottom-support a rapid vibratory motion while the bag is being filled, said vibrator consisting of a pitman secured to the lower bag-support and moving in one direction in opposition to the spring-support.

38. In a machine for filling bags or receptacles, the combination of a bag-filling device with means for supporting the top of the bag and a bottom-support for the bag, spring-bars upon which bottom-support rests, and a vibrator which tends to move the bag-support up and down while the bag is being filled.

39. In a machine for filling bags or receptacles, the combination of a bag-filling device with means for supporting the top of the bag and a bottom-support for the bag, spring-bars upon which bottom-support rests, and a vibrator which tends to move the bag-support up and down while the bag is being filled, said vibrator consisting of a pitman secured to the bag-support and working substantially at right angles to the length of the spring-bars.

40. In a machine for filling bags or receptacles, the combination of means for filling the bags with an upper bag-support for holding the bag while it is being filled, a lower bag-support for holding the bag while it is being filled, a pitman rigidly attached to the lower bag-support at one end and driven by an eccentric at the other end so as to give the bag-support a combined vertical and lateral motion, and a spring-support which operates upon the bottom bag-support in the direction outwardly along the line of the pitman while the bag is being filled.

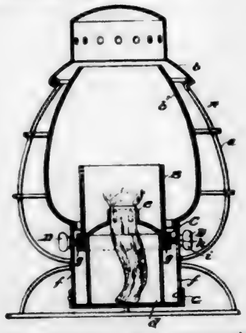
41. In a machine for filling receptacles, the combination of a supporting-frame with a supply-hopper-discharging portion vertically adjustable on the frame, a bag-supporting device on the frame, a series of devices for receiving the material from the hopper-discharging portion and conveying it to the bag, said series of devices vertically adjustable along the supporting-frame and containing parts which, with the discharge portion, form a measuring device adapted to be varied by the adjustment of the hopper-discharge portion with reference to the devices which receive the material from the hopper-discharge and convey it to the bag, and means for connecting such series of devices with the hopper-discharging portion so that the two can be vertically adjusted together on the frame.

42. In a machine for filling receptacles, the combination of a suitable support for the receptacle, with a discharge part to discharge the material into the receptacle, a supply part to contain the supply of material, a measuring device interposed between the discharge and the supply, and consisting of two telescopic portions, a means for adjusting the two telescopic portions with reference to each other, means for varying the distance between the support and the discharge, and means for adjusting the supply part and the discharge part simultaneously with reference to the support for the receptacle.

43. In a machine for filling receptacles, the combination of a receptacle-support with a discharge device adapted to discharge the material into the receptacle, and a supply device adapted to hold the supply, a measuring device comprising two telescopic parts, one associated with the discharge device, and the other with the supply device, and means for adjusting the supply part and the discharge part simultaneously with reference to the support for the receptacle.

44. In a machine for filling bags or receptacles with powdery or granular substance, the combination of a feed mechanism adapted to introduce the material into the bag in a relatively small stream, with a bottom-support for the bag and a top-support for the bag and trip mechanism operable at will for the bottom-support whereby the latter may be removed at the will of the operator to permit the bag to fall when the operator so desires.

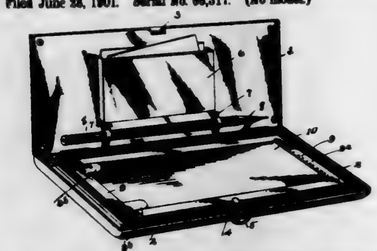
707,545. SIGNAL-LANTERN. GEORGE H. BRADBY, St. Paul, Minn., assignor of one-half to George Gobiisch, St. Paul, Minn. Filed Mar. 10, 1902. Serial No. 97,633. (No model.)



Claim.—The herein-described signal-lantern consisting essentially of the white shade, the casing *c* provided at diametrically opposite points with the vertical slots *f*, the removable oil-cup, of less diameter than the casing *c*, arranged in said casing, the colored-glass shade B surrounding the oil-cup and adjustable vertically between the same and the casing *c*, the heavy metallic band C secured on the exterior of the lower portion of the shade, whereby weight is lent to the shade, and the same is enabled to quickly fall when released; said band C having threaded sockets at diametrically opposite points, and being also adapted to prevent breakage of the shade B when the same falls, and the screws D having

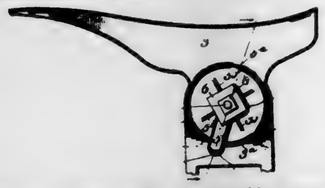
threaded shanks extending through the slots *f* of the casing *c* and into the threaded sockets in the metallic band C, and also having heads arranged to bind against the outer side of the casing *c*, all as and for the purpose set forth.

707,546. **DOOR-PLATE.** CHARLES D. BROOKS, Coshocton, Ohio. Filed June 28, 1901. Serial No. 66,317. (No model.)



Claim.—In a door-plate, the combination with a plate-section 1 adapted to be fixed in connection with a door, a card-receptacle thereon, and pencil-holding keepers secured to said door adjacent to said receptacle, of a plate-section 2 hinged to the section 1 and having a pad-receiving frame on its inner side, fingers 9^a projecting inward from said frame and adapted to aid in holding the pad within the same, and means for detachably latching said sections in connection with each other, substantially as specified.

707,547. **HINGE-JOINT FOR SEATING.** FIRLEY S. BROOKS, Cincinnati, Ohio. Filed May 5, 1902. Serial No. 105,950. (No model.)



Claim.—1. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinge member having radial ball-grooves, the other hinge member having transverse ball-grooves, antifriction-balls located at the crossing of the ball-grooves and limiting the movement of the seat-bracket, and adapted to interlock, and travel in the ball-grooves of both hinge members to provide an antifriction-bearing between the meeting faces thereof, and means for securing the parts of the hinge-joint together.

2. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinge member having radial ball-grooves, the other hinge member having transverse ball-grooves, with their ends turned inward toward the outer ends of the radial grooves, antifriction-balls located at the crossing of the ball-grooves and limiting the movement of the seat-bracket, and adapted to interlock, and travel in the ball-grooves of both hinge members to provide an antifriction-bearing between the meeting faces thereof, and means for securing the parts of the hinge-joint together.

3. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinge member having radial ball-grooves, the other hinge member having transverse ball-grooves, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves, and adapted to interlock, and travel in, the ball-grooves of both hinge members, and yielding means for securing the parts of the hinge-joint together.

4. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members having radial and transverse ball-grooves respectively, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves and adapted to interlock, and travel in, the ball-grooves of both hinge members and yielding means for securing the parts of the hinge-joint together.

5. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinged member having radial ball-grooves, the other hinge member having transverse ball-grooves, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves and adapted to interlock, and travel in, the ball-grooves of both hinge members and means for securing the parts of the hinge-joint yieldingly together.

6. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinge member having radial ball-grooves, the other hinge member having transverse ball-grooves provided with inclines leading to the bearing-face at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves and adapted to interlock, and travel in, the ball-grooves of both hinge members and means for securing the parts of the hinge-joint yieldingly together.

7. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members, one hinge member having radial ball-grooves, the other hinge member having transverse ball-grooves provided with inturned ends, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves and adapted to interlock, and travel in, the ball-grooves of both hinge members and yielding means for securing the parts of the hinge-joint together.

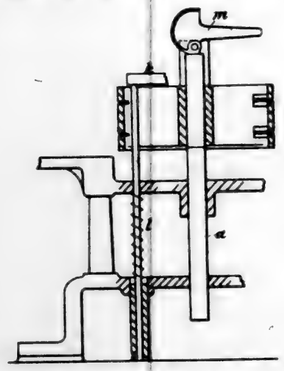
8. A hinge-joint for seating comprising a support, a seat-bracket, inner and outer hinge members one hinge member having three radial ball-grooves, the other hinge member having three transverse ball-grooves arranged in approximately triangular form, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves, and adapted to interlock, and travel in, the ball-grooves of both hinge members, and yielding means for securing the parts of the hinge-joint together.

9. A hinge-joint for seating comprising a support having a boss, a seat-bracket having a housing provided with a web formed with a thimble fitting around the boss, a member of the hinge-joint, having radial ball-grooves and located within the housing, the other member of the hinge-joint having transverse grooves and located within the housing, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves, and yielding means for securing the parts of the hinge-joint together.

10. A hinge-joint for seating, comprising a support having a stop-lug a recessed lug, and a boss, a seat-bracket having a web provided with a segmental opening receiving the stop-lug, and a thimble fitting around the boss, a member of the hinge-joint having radial ball-grooves and secured to the seat-bracket, the other member of the hinge-joint having transverse ball-grooves and a radial arm provided with a hook engaging with the recessed lug, inclines leading to the bearing-faces at the ends of the ball-grooves, antifriction-balls located at the crossing of the ball-grooves, and yielding means for securing the parts of the hinge-joint together.

11. A hinge-joint for seating comprising a support having a boss, and a recessed lug, a seat-bracket having a housing formed with an annular shoulder having a retaining-lug, and a web formed with a thimble fitting around the boss, a movable member of the hinge-joint having a peripheral recess receiving the retaining-lug, and radial ball-grooves, the other fixed member of the hinge-joint having transverse ball-grooves, inclines leading to the bearing-faces at the ends of the ball-grooves, and a radial arm provided with a hook engaging the recessed lug, antifriction-balls located at the crossing of the ball-grooves, and means for securing the parts yieldingly together.

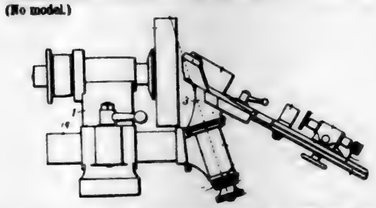
707,548. **TYPE-WRITER.** WALTER H. CAMPBELL, Kiev, Russia. Filed Mar. 31, 1902. Serial No. 100,796. (No model.)



Claim.—1. In type-writing machines, the combination of a fixed circular anvil, two or more shuttles around the circumference thereof, fins on such shuttles, gaps in such fins, and a spring driving-arm engaging the said gaps, substantially as herein set forth.

2. In type-writing machines, the combination of two or more shuttles one above the other in a circular anvil, a driving-arm for said shuttles, means for bringing into gear with the driving-arm the one required at the level of impression by altering the position axially of the anvil on its shaft and causing the other to remain idle, and stops for holding the idle shuttle centrally so that it shall come truly into gear with the driving-arm when brought into action, substantially as herein set forth.

707,549. **MACHINE FOR GRINDING TWIST-DRILLS.** CLARENCE A. CHANDLER, Worcester, Mass. Filed Dec. 22, 1899. Serial No. 741,270. (No model.)



Claim.—1. In a drill-grinding machine, the combination of a supporting-stand for a drill-holder and provided with a journal-bearing, an oscillating drill-holder provided with a spindle passing through said journal-bearing, an eccentric sleeve inclosing said spindle and journaled in said bearing, means for adjustably attaching said sleeve to said spindle, substantially as described.

2. In a drill-grinding machine, the combination with a supporting-stand, a grinding-wheel, and a drill-holder journaled in said stand, whereby it is capable of an oscillating motion to rock the lip of the drill in contact with the grinding-wheel, of a sleeve journaled in said supporting-stand and adjustably attached to the drill-holder, whereby the axis of oscillation of the drill-holder is varied, substantially as described.

3. The combination of a supporting-stand, a drill-holder having a screw-threaded spindle, an eccentric sleeve held on said spindle and journaled in said stand, a clamping-nut on said spindle, whereby said sleeve is held from rotating on said spindle, and a graduated collar having a spline connection with the spindle and held between said nut and said sleeve, whereby the position of said sleeve relatively to said spindle is determined, substantially as described.

4. The combination of a stand, a drill-holder provided with a spindle, an eccentric sleeve adjustably held on said spindle and journaled in said stand, means for rotating said sleeve on said spindle and means for holding said sleeve from rotation on said spindle, and allowing it to oscillate in said stand, whereby the axis of oscillation of the drill-holder is varied, substantially as described.

707,550. **SELF-HEALING MATERIAL.** GEORGE H. CHISHOLM, Brooklyn, N. Y., assignor, by direct and mesne assignments, to J. J. Nichols and H. H. Janderf, New York, N. Y., and S. S. Ryckman, Grimsby, Ontario, Canada. Filed Apr. 24, 1896. Serial No. 588,969. (No specimens.)

Claim.—A composition of matter, consisting of a pasty mass of gum-caoutchouc, wax, resinous gums and volatile oils in suitable proportions, hermetically sealed between layers of rubber and inserted within the walls of the article in which it is to be used, in substantially the manner set forth.

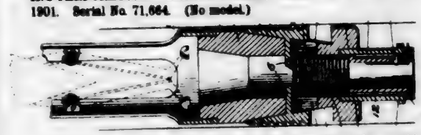
707,551. **METHOD OF ELIMINATING METALS FROM MIXTURES OF METALS.** GUILLIAN H. CLARKE, Philadelphia, Pa. Filed Jan. 15, 1902. Serial No. 89,866. (No specimens.)

Claim.—1. The method of eliminating and replacing part of an alloy, which consists in fusing the alloy and a flux and a chemical metallic compound of which the base is to replace the part to be eliminated and of which the heat of formation is less than that of the part to be eliminated, whereby the chemical compound is reduced and its base enters the alloy and whereby the part to be eliminated enters into the chemical compound and is taken up by the slag, substantially as described.

2. The method of eliminating zinc from alloys of copper containing zinc and replacing it by lead, which consists in heating the alloy in contact with oxid of lead held in solution by a flux, whereby the zinc reduces the oxid of lead to metallic lead which enters the alloy forming an alloy of copper containing lead and whereby the zinc enters the slag in solution as zinc oxid, substantially as described.

3. The method of eliminating and replacing part of a copper alloy, which consists in fusing the alloy and a flux and a chemical metallic compound of which the base is to replace the part to be eliminated and of which the heat of formation is less than that of the part to be eliminated, whereby the chemical compound is reduced and its base enters the alloy, and whereby the part to be eliminated enters into the chemical compound and is taken up by the slag, substantially as described.

707,552. **AUTOMATIC STOP AND LOCK FOR OIL-WELL-CASING PERFORATORS.** THOMAS E. CLARK, Visalia, Cal. Filed Aug. 10, 1901. Serial No. 71,664. (No model.)



Claim.—1. In an oil-well tool of the class described, the combination of a tubular body, vertically-movable locking devices thereon, to engage the casing and lock the tool against descent therein, a sleeve detachably connected to the lower end of the body and having an inwardly-extending flange at its lower end, a vertically-movable plunger in said sleeve, a spring-pressed detent, carried by said plunger, to engage the flange and lock the plunger in an elevated position, and a yielding connection between the plunger and the locking devices, whereby the latter are operated by the plunger, substantially as described.

2. In an oil-well tool of the class described, the combination of a tubular body having downwardly-converging slotted sides forming slideways, wedge-clutches, on said slideways having guide-pins in the slots of the body, a vertically-movable plunger, projecting from the lower end of the body, means to lock the plunger in an elevated position, and a spring, compressed by the upward movement of the plunger and connected to the wedge clutches, substantially as described.

3. An oil-well tool of the class described having a plunger at its lower end, locking devices to engage the casing and lock the tool against descent therein, a spring, compressed by the upward movement of the plunger and connected to the locking devices to actuate the same, and means to lock the plunger in an elevated position, substantially as described.

4. An oil-well tool of the class described, having a plunger at its lower end, wedge-clutches, a spring connecting said plunger and said wedge-clutches, and a spring-pressed detent to lock said plunger in an elevated position, substantially as described.

5. In an oil-well tool of the class described, the combination of locking devices to engage the casing and lock the tool against descent therein, a vertically-movable plunger, a yielding connection between the plunger and the locking devices, and means to lock said plunger in an elevated position, substantially as described.

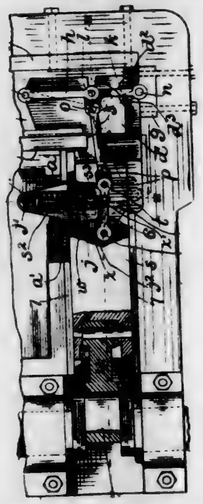
6. In an oil-well tool of the class described, the combination of locking devices to engage the casing and lock the tool against descent therein, a vertically-movable plunger, a yielding connection between the plunger and the locking devices, and a spring-pressed detent to lock said plunger in an elevated position, substantially as described.

7. In an oil-well tool of the class described, the combination of locking devices to engage the casing and lock the tool against descent therein, a vertically-movable plunger, a spring, compressed by the ascent of the plunger and connecting the latter to said locking devices, and a spring-pressed detent to lock said plunger in an elevated position, substantially as described.

707,553. **PRESSURE-EXERTING MACHINE.** JOSEPH A. COSTELLO and WILLIAM S. BUHLE, Cleveland, Ohio. Filed June 2, 1902. Serial No. 109,961. (No model.)

Claim.—1. The combination, with the stationary portion of the machine; a pressure-exerting member capable of reciprocation; means for guiding the said pressure-exerting member; a toggle-joint operatively connected, at one end, with the said pressure-exerting member and attached, at its opposite end, to the stationary portion of the machine; a slide arranged to travel at one side of and toward and from the travel of the aforesaid pressure-exerting member and provided, at the bottom, with an extension which is rigid with the slide and projects toward the travel of the said pressure-exerting member; means for guiding the slide, and means for actuating the slide, of another and laterally-yieldable toggle-joint arranged over the said slide extension and operatively connected with the slide at one end and operatively attached, at its opposite end, to the first-mentioned toggle-joint and normally having its links somewhat out of line; a stop-forming member provided upon the slide extension and ar-

ranged to prevent the movement of the said links into line, and yieldable means acting to retain the said links in their normal position.



2. The combination, with the stationary portion of the machine; a pressure-exerting block capable of reciprocation; means for guiding the said block; a toggle-joint operatively connected, at one end, with the said block and attached, at its opposite end, to the stationary portion of the machine; a slide arranged to travel at one side of and toward and from the travel of the aforesaid block and provided, at the bottom, with an extension which is rigid with the slide and projects toward the travel of the said block and has a stop-forming lug upon its upper side; means for guiding the slide, and means for actuating the slide, of another and laterally-yieldable toggle-joint arranged over the slide extension and operatively connected with the slide at one end and operatively attached, at its opposite end, to the first-mentioned toggle-joint; yieldable means acting to retain the second-mentioned toggle-joint in its normal position, and the arrangement of the parts being such that the links of the said second-mentioned toggle-joint, in the normal position of the parts, abut against the aforesaid lug and are somewhat out of line in the direction opposite to the direction of action upon the said toggle-joint by the means which, as aforesaid, acts to retain the said toggle-joint in its normal position.

3. The combination, with the stationary portion of the machine; a pressure-exerting block capable of reciprocation; means for guiding the said block; a toggle-joint operatively connected, at one end, with the said block and attached, to the stationary portion of the machine; a slide capable of reciprocation and arranged to travel at one side of and toward and from the travel of the aforesaid block; means for guiding the slide, of another and laterally-yieldable toggle-joint operatively connected with the slide at one end and operatively and directly attached, at its opposite end, to the first-mentioned toggle-joint and having its links normally out of line laterally in one direction; a stop arranged to prevent the movement of the said links into line in the opposite direction, and yieldable means acting to retain the said second-mentioned toggle-joint in engagement with the said stop.

4. The combination, with the stationary portion of the machine; a pressure-exerting block capable of reciprocation; means for guiding the said block; a toggle-joint operatively connected, at one end, with the said block and attached, at its opposite end, to the stationary portion of the machine; a slide capable of reciprocation and arranged to travel at one side of and toward and from the travel of the aforesaid block; means for guiding the said slide, and means for actuating the slide, of another and yieldable toggle-joint operatively connected with the slide at one end and operatively attached, at its opposite end, to the first-mentioned toggle-joint and having its links normally out of line; a stop arranged to prevent the movement of the said links into line and carried by the slide; a rod pivotally attached, at one end, to one of the said links; a case surrounding the said rod; a spiral spring confined and coiled upon the said rod within the said case and acting to retain the second-mentioned toggle-joint against the aforesaid stop, and the said case being pivotally supported from the slide and the arrangement of the parts being such that the said case shall be capable of oscillating during the yielding of the second-mentioned toggle-joint against the action of the aforesaid spring.

5. The combination, with the stationary portion of the machine; a pressure-exerting block capable of reciprocation; means for guiding the said block; a toggle-joint operatively connected, at one end, with the said block and attached, at its opposite end, to the stationary portion of the machine; a slide capable of reciprocation and arranged to travel at one side of and toward and from the travel of the aforesaid block, which slide is provided, at the bottom, with an extension which projects toward the travel of the pressure-exerting block, of another and laterally-yieldable toggle-joint arranged over the slide extension and vertically pivoted to the slide at one end and directly attached, at its opposite end, to the first-mentioned toggle-joint and having its links normally somewhat out of line; a stop provided upon the slide extension and arranged to prevent the movement of the said links into line and a suitably-applied spring acting to retain the second-mentioned toggle-joint in engagement with the said stop.

6. The combination, with the stationary portion of the machine; a pressure-exerting block capable of reciprocation; means for guiding the said block; a toggle-joint operatively connected, at one end, with the said block and attached, at its opposite end, to the stationary portion of the machine; a slide capable of reciprocation and arranged to travel at one side of and toward and from the travel of the aforesaid block and provided, at the bottom, with an extension which projects toward the travel of the pressure-exerting block and is provided, at one side, with two arms arranged one above the other and a suitable distance apart, and has a stop-forming lug; means for guiding the slide, and means for actuating the slide, of another and laterally-yieldable toggle-joint arranged over the slide extension and operatively connected with the slide at one end and operatively attached, at its opposite end, to the first-mentioned toggle-joint and normally having its links somewhat out of line and engaging the aforesaid lug; a case arranged longitudinally between and pivoted vertically to the aforesaid arms; a rod pivoted vertically at one end to one of the said links and extending into and longitudinally of the said case, which rod is provided at its free end with a head or shoulder; a ring surrounding the rod at the free end of and attached to the case, and a spiral spring coiled around the rod between the said ring and the aforesaid shoulder or head.

707,554. LETTER-BOX. JACOB E. COURSEN, Wilmington, Del. Filed Dec. 7, 1901. Serial No. 85,026. (No model.)

Claim.—1. The combination with a box having a cut-off arranged within the letter drop-opening, of a signal-carrier operatively connected with the said cut-off, whereby a signal is displayed when the cut-off is turned to allow ingress to the box through the drop-opening and withdrawn when said cut-off is turned to its opposite position to close the said drop-opening, substantially as shown and described.

2. The combination with a box having a cut-off, at the letter drop-opening, of a reversible signal-carrier connected with the said cut-off, whereby the cut-off is operated and a signal displayed and withdrawn, substantially as described.

3. The combination with a box having a cut-off at the letter drop-opening, and an outwardly-opening door at one side of the box, of a reversible signal-carrier connected with the cut-off, and adapted to display and withdraw a signal, one end of said carrier being adapted to extend across the door when the signal is displayed, substantially as described.

4. In a letter-box having a drop-opening formed in the front thereof, a cylinder arranged therein and adapted for opening and closing the drop-opening, an arm connected to the cylinder and carrying a signal device, whereby through the movement of the arm the drop-opening will be closed or opened and the signal respectively withdrawn or displayed, substantially as shown and described.

5. In a letter-box having a drop-opening arranged in the front and a door arranged upon the side thereof, a shaft journaled in the front of said box, a cylinder arranged upon the shaft and having a portion of its periphery cut away a tubular link-shaped arm arranged upon one end of the shaft, a signal carried by the said arm, and means for opening and closing the said drop-opening and respectively displaying or withdrawing the signal, substantially as shown and described.

6. A letter-box having a drop-opening arranged in the front thereof, a door hinged to the side of said box, a shaft mounted in the front of the box and having a cylinder mounted thereon which is adapted to operate in the said drop-opening, a tubular link-shaped arm arranged upon the shaft and having one portion thereof cut out, rollers journaled in the ends of the arm, a cord or cable held within the said arm and having a flexible signal secured thereto, and a weight arranged upon the cord, substantially as shown and described.

7. A letter-box having a drop-opening arranged in the front and a door upon the side thereof, a shaft journaled in the front of said box and having a cylinder mounted thereon whose periphery is cut away upon one side, a signal-carrying arm arranged upon the shaft and means arranged within the said arm for carrying a signal and adapted to be displayed when the cylinder is turned to allow ingress to the box and adapted to be withdrawn when the cylinder is revolved to close the said drop-opening and preventing ingress to the box, the said arm being held across or in alinement with the door when the cylinder is in position to allow ingress to the box, and a stop-pin arranged upon the box for holding the arm in such position substantially as shown and described.

8. A letter-box having a drop-opening formed in the front thereof, an arm mounted upon the side of the box, a cord arranged within the arm and having a signal thereon and a cylinder arranged within the drop-opening and adapted to be turned by the arm, the said cylinder having a portion of its periphery cut away and means arranged within the arm whereby to cause the signal to be displayed when the arm is turned to revolve the cylinder to allow ingress through the opening in the box and the said signal withdrawn when the arm is turned to cause the said cylinder to close the said drop-opening, substantially as shown and described.

707,555. MERRY-GO-ROUND, SEESAW, AND JOGGER-BOARD ATTACHMENT. WALTER W. CURTRIGHT, Atlanta, Ga. Filed Sept. 16, 1901. Serial No. 75,555. (No model.)

Claim.—1. In a device of the kind described, the combination of an essentially spherical-shaped casting having arms projecting downwardly therefrom, and an aperture produced centrally therein, supporting-legs connected to the arms and having their lower ends terminating in lateral foot portion, a bracket having a slot produced centrally therein, arms projecting from the periphery of the said bracket and having their outer ends terminating in rest portions from which project finger portions that form guides, a board held upon the rests, and a bolt passing through the said slot in the bracket and engaging the aperture in the casting, substantially as shown and described.

2. In a device of the kind described, the combination of a spherical-shaped casting having an aperture arranged therein and downwardly-projecting arms integrally formed upon the edges thereof, a spherical-shaped bracket fitting upon the casting and having a slot arranged therein, a bolt passing through the said slot and aperture, arms projecting from the bracket and having their upper ends terminating in rest portions, a board held by the said arms and resting upon the rest portions, a bracket hinged to one end of the said board and having its lower end provided with shoulders, extensions pivoted to the bracket and a ball-shaped arm carried by the bracket and a clip arranged on the said board for holding the bracket in an open position, substantially as shown and described.

3. In a device of the kind described, the combination of a tripod-shaped stand, the legs of which are connected at their upper ends to descending arms of a casting, the upper surface of which is essentially spherical-shaped and provided with an aperture, a bracket having a recess formed therein to snugly fit over the spherical-shaped surface of the casting, and having a slot arranged therein, a bolt protruding through the aperture and slot for holding the said bracket to the stand, arms protruding from the bracket, and a board supported by the bracket-arms, substantially as shown and described.

4. The combination of a tripod-shaped stand, the legs of which are connected at their upper ends to a casting the upper surface of which is essentially spherical-shaped and provided with an aperture, a bracket having a recess to snugly fit the said casting and having a slot arranged therein, a bolt protruding through the said aperture and slot for holding the said bracket in position, arms protruding from the bracket and having guides formed at their upper ends, a board adapted to slide in the said guides and held thereby and means for holding the board in a steady position, substantially as shown and described.

5. In a supporting-bracket for a device of the kind described, the combination of a board, a bracket hinged thereto at one end and having its opposite or free end provided with shoulders, extensions pivoted to the said bracket and adapted to rest against the said shoulders when adjusted outwardly or extended, a ball connected to the bracket, a clip carried by the said board and adapted for engagement by the ball when the rest is extended or opened, and a hook for engagement with the bracket to hold it in a closed or folded position against the said board, substantially as shown and described.

707,556. TROUSERS. GEORGE M. DARE, Worcester, Mass. Filed Mar. 7, 1901. Serial No. 50,230. (No model.)

Claim.—1. As an article of manufacture, the two-seam trousers constructed as hereinbefore described, each leg and body half comprised in a single piece without a seam at the outer side of the leg or thigh, and having at the side or along the median fold-line, from about the knee upward, an outwardly-inclined lateral deflection of the fabric relatively to the portion below, affording in the unseamed outer side portions an outward conformation for fitting the outer thigh, the said pieces being formed and fitted with permanent upwardly-distended areas in the fabric at the inner thigh, adjacent to and below the crotch, substantially as and for the purposes set forth.

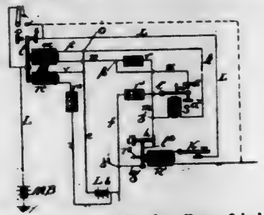
2. The two-seam trousers hereinbefore described, each half or leg comprised in a single piece without a seam at the outer side of the leg or thigh, and having the cloth at the inner thigh portions, from near the median line to the seaming edges, adjacently below the crotch, formed with upwardly-distended areas of the fabric, as specified, the side portions from above the knee upward, having a bodily lateral deflection outward beyond the normal side fold *x'*, thereby giving the unseamed fabric an outstanding conformation and fullness at the thigh along the median side line, relatively to the portions below, and having its hip-form reduced and fitted with a closed-in excision at the back, said excision being disposed transverse to the back seam, below and approximately parallel with the top or waist line, substantially as set forth.

3. A trousers-garment comprising a united pair of leg-blanks, each consisting of a single piece of fabric devoid of an outer leg-seam, the blank for each half having its edges and crotch-points cut to the form shown and described, and having its upper front and back portions skewed toward the median line and presenting at the thigh an outstanding convergent fullness 20 beyond the normal plane or fold, said blank provided with longitudinally-distended areas of the fabric at *b* and *f*, corresponding to the inner thigh, adjacently below the crotch-points, substantially as and for the purpose set forth.

707,557. TELEGRAPHIC APPARATUS. CHARLES M. DAVIS, Chicago, Ill. Filed July 27, 1901. Serial No. 69,998. (No model.)

Claim.—1. In a telegraphic apparatus, a main-line circuit including a fixed contact, a vibrating lever coöperating therewith, devices for controlling the vibrating movements of said lever to open or close said main-

line circuit, a relay, a sounder, and means actuated by said relay for operating said controlling devices, as and for the purpose set forth.



2. In an apparatus for avoiding the effects of leaks or escapes in telegraph-lines, the combination with the main line including a main battery, of a circuit-breaker interposed in the main line and intermediate the leak or escape and the battery and comprising a fixed contact and a vibrating lever arranged to coöperate therewith to open and close the main line, and means controlled by the opening of a key in the main line on one side of the leak or escape for rocking said lever to open the line connection with the main battery on the other side of the leak or escape, whereby all current is withdrawn from the line between said key and circuit-breaker, as and for the purpose set forth.

3. In an apparatus for avoiding the effects of leaks or escapes in telegraph-lines, a main line including a main battery, in combination with a vibrating lever, and a coöperating contact interposed in the main-line connection with said battery and between the battery and the leak or escape, means normally tending to hold said vibrating lever in closed relation with respect to its coöperating contact, and means actuated coincidently with the opening of a key in the main line on the opposite side of the leak or escape for rocking said lever out of coöperating relation with said contact momentarily to break the main-line connection with the battery, as and for the purpose set forth.

4. In an apparatus for avoiding the effects of leaks or escapes in telegraph-lines, a main-line connecting terminal or battery stations, a circuit-breaking device interposed in the main line intermediate said line and its battery connection and comprising a fixed contact and a vibrating lever coöperating therewith, electrical devices operating to normally maintain said lever in closed relation with respect to said contact, means operating upon said lever and constantly tending to withdraw said lever from said contact, a local circuit for controlling said electrical devices, and means actuated by the opening of a key in said main line on the opposite side of the leak or escape for controlling said local circuit, as and for the purpose set forth.

5. In an apparatus of the class described, a main line, a main-battery connection therefor, a pivoted switch-lever and a coöperating fixed contact arranged in said main-battery connection, electrical devices for rocking said switch-lever toward and from said contact, a local circuit for said electrical devices, and means controlled by the opening of a key at a distant transmitting-station for controlling the circuit of said electrical devices to momentarily open said switch-lever to break said main-line connection with the main battery, as and for the purpose set forth.

6. In an apparatus of the class described, a main line, a battery connection therefor, a line-adjuster mechanism including a switch arranged in said battery connection, magnets arranged to actuate said switch, one of said magnets tending to open the switch and the other to close the same, local circuits for said magnets, and means actuated by the opening of said line-circuit at a distant transmitting-station for controlling the circuit of one of said magnets, as and for the purpose set forth.

7. In an apparatus of the class described, a main line, a battery connection therefor, a fixed contact and a lever arranged in said battery connection, said lever coöperating with said fixed contact to make and break the connection of said battery to said main line, an attracting-coil and a retracting-coil operating on said lever, local circuits for said coils, and means actuated by the opening of said line-circuit at a distant transmitting-station for controlling the circuit of said attracting-coil, as and for the purpose set forth.

8. In an apparatus of the class described, a main line, a main-battery connection therefor, a switch-lever arranged in said connection, electrical devices for controlling said switch-lever, a local battery, a sounder-circuit including said battery, said sounder-circuit having a branch which also includes said electrical devices, and a local relay for controlling said sounder-circuit, as and for the purpose set forth.

9. In an apparatus of the class described, a main line, a main-battery connection therefor, a switch-lever arranged in said connection, an attracting-coil and a retracting-coil for said lever, a local battery, a circuit for said retracting-coil including said battery, a sounder, a circuit therefor including said local battery, said sounder-circuit having a branch including said attracting-coil, an auxiliary circuit for said attracting-coil, said auxiliary circuit being controlled by said sounder, and a relay for controlling said sounder-circuit, as and for the purpose set forth.

10. In an apparatus of the class described, a main line, a main battery connected thereto, a circuit-breaking lever arranged in said battery connection, an attracting-coil and a retracting-coil for actuating said lever, a local battery, circuit connections from said local battery for said retracting-coil, a sounder, a circuit for said sounder including said battery, said sounder-circuit having a branch including said attracting-coil, a relay arranged in the main line for controlling said sounder-circuit and its branch, an auxiliary circuit for said attracting-coil, said auxiliary circuit being controlled by said sounder, and resistances arranged in said attracting and retracting coils circuits whereby the currents therein may be varied, as and for the purpose set forth.

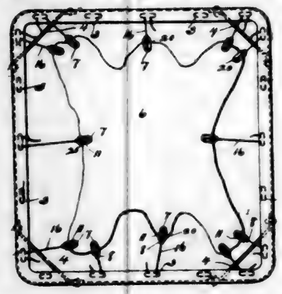
11. In an apparatus for avoiding the effects of leaks or escapes in telegraph-lines, a main line including a main battery, a circuit-breaker interposed between said battery and main line, means actuated by the opening of a key in the main-line circuit at a distant transmitting-station for temporarily actuating said circuit-breaker to open said line-circuit to battery, a shunt around said circuit-breaker, and devices arranged in said shunt for diminishing the current to the main line when said circuit-breaker is open, as and for the purpose set forth.

707,558. COMBINED UNDERVEST AND CORSET-COVER. CORINNE DUFOUR, Savannah, Ga. Filed Aug. 26, 1901. Serial No. 73,227. (No model.)

Claim.—1. A combined undervest and corset-cover, comprising a body having front and rear flaps at the upper end of the body, means for securing the outer corners of the flaps together to form a scye, and sleeves for removable connection with the said scye, as set forth.

2. A combined undervest and corset-cover, comprising a tubular body having a front and rear flap extending from its upper end, tying-bands at the corners of each of the flaps, said bands serving to secure the corners of the flaps together when extended to form scyes and to independently secure them in position when folded down, and sleeves for detachable connection with the said scyes, as set forth.

707,559. HIDE-SECURING APPARATUS. HUGH Y. B DUFF, Cheswick, Pa. Filed Dec. 30, 1901. Serial No. 87,701. (No model.)



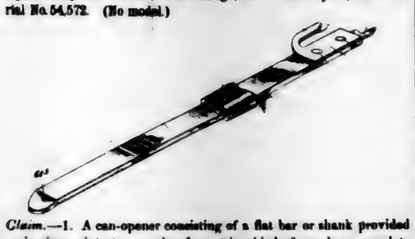
Claim.—1. An apparatus for the purpose set forth, comprising in combination a metal frame, a plurality of hide-engaging clips, having flexible extensions, and means for adjustably connecting said clip extensions with said frame.

2. An apparatus for the purpose set forth, comprising in combination a metal frame, a plurality of spring hide-engaging clips provided with flexible extensions, and means carried by said frame to adjustably engage said clip extensions.

3. An apparatus for the purpose set forth, comprising in combination a metal frame having fasteners on one side thereof, and hide-engaging clips provided with flexible extensions to adjustably engage with said frame-fasteners.

4. An apparatus for the purpose set forth, comprising in combination a metal frame having a series of fasteners on one side thereof each consisting of two oppositely-inclined tongues, and a plurality of spring hide-engaging clips having flexible extensions to engage said frame-tongues.

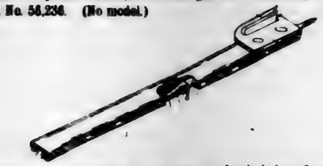
707,560. CAN-OPENER. MAX R. DUNCAN, New York, N. Y., assignor to Byron R. Bacon, South Orange, N. J. Filed Apr. 6, 1901. Serial No. 54,572. (No model.)



Claim.—1. A can-opener consisting of a flat bar or shank provided with a piercing-point at one end and a cutting-blade formed upon a plate attached to the said flat bar or shank, in combination with a sliding piece having overlapping flanges which are adapted to engage around the edges of the said shank and a cutting-blade formed upon a projecting shank extending from the said sliding piece and engaging along the under side of the shank, substantially as described.

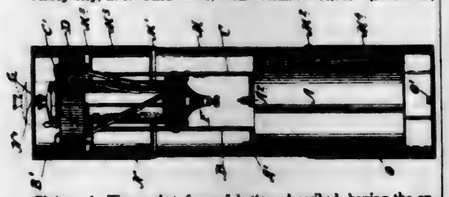
2. In a can-opener a flat bar or shank provided with a piercing-point at one end and a cutting-blade formed upon a plate attached to the said flat bar or shank, in combination with a sliding piece adapted to move along the said shank, overlapping flanges formed upon the sliding piece and adapted to engage around the edge of the shank and hold the sliding piece upon same, a projecting shank formed upon the said sliding piece and engaging along the under side of the shank and a cutting-blade formed upon the end of the said shank, substantially as described.

707,561. CAN-OPENER. MAX R. DUNCAN, New York, N. Y., assignor to Byron R. Bacon, South Orange, N. J. Filed May 1, 1901. Serial No. 56,236. (No model.)



Claim.—In a can-opener comprising a shank, ledges formed by the turned-over edges of said shank, a cutting-blade formed upon a plate and attached to the end of said shank and a piercing-point formed integrally upon said plate, in combination with a sliding cutting-blade adapted to move along said shank and held upon same by means of the aforesaid ledges or turned edges, substantially as described.

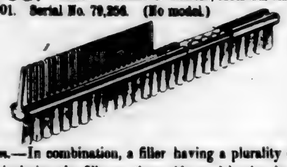
707,562. ELECTROTHERAPEUTIC BATTERY. THOMAS J. DUNN, Jersey City, N. J. Filed Jan. 3, 1902. Serial No. 88,308. (No model.)



Claim.—1. The pocket form of battery described, having the cylindrical battery A, with the vibrator and regulator and connections at one end thereof, and having a head D of slightly-larger diameter, in combination with the cylindrical casing M, extensions M' M³, external stops M² M⁴ and internal stop M⁵, all arranged to serve substantially as herein specified.

2. The pocket form of battery described, having the cylindrical battery A, with the vibrator and regulator, and connections at one end thereof, and having a head D of slightly-larger diameter, in combination with the casing M, end portions M' M³, external beads M² M⁴, and internal bead M⁵, and with the caps N N', O O', adapted to perform the double function of coverings to inclose the other parts and of handles to be grasped by the patient, all substantially as herein specified.

707,563. COMB. ALFRED B. DURGIN, Medford, Mass. Filed Oct. 19, 1901. Serial No. 79,256. (No model.)



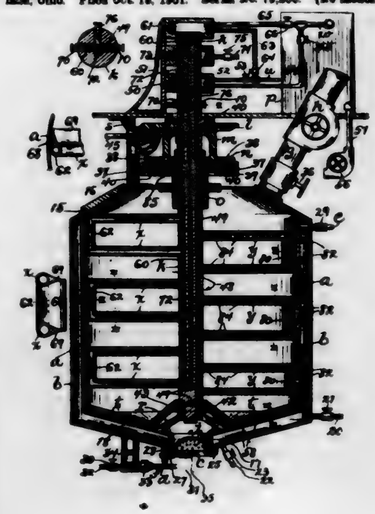
Claim.—In combination, a filler having a plurality of openings, a metal cap inclosing the filler on three sides and having its edge portions inwardly bent and spaced from the back of the filler, the space being of uniform area throughout the length of the filler, the cap having openings in register with the openings of the filler, tufts fitted in the openings of the cap and filler, and a comb having external ribs along the outer edge of its back to engage under the bent edges of the said cap by a longitudinal sliding movement, substantially as described.

707,564. COMB. ALFRED B. DURGIN, Medford, Mass. Filed Oct. 19, 1901. Serial No. 79,257. (No model.)

Claim.—1. In combination, a brush, a cap embracing the face and sides of the brush-back and having a portion of the rim extended, and a comb having its back fitted into the cap by springing the extended portion of the rim thereover, substantially as described.

2. In combination, a strip, a metal cap fitted to and embracing three sides of the strip and indented to hold the said strip in place, tufts fitted into openings in the strip and face of the cap, and a comb having its back fitted into the cap by springing a portion of the rim thereover, substantially as specified.

707,565. RENDERING APPARATUS. EUGENE R. EDSON, Cleveland, Ohio. Filed Oct. 19, 1901. Serial No. 79,200. (No model.)



Claim.—1. Apparatus of the character indicated, comprising a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, a pump having its inlet in open relation with the said vapor-outlet; means for heating the receptacle; a shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting arms having passage-ways formed therein and extending longitudinally thereof, which arms have orifices discharging into the receptacle; means for supporting the shaft; means for operating the shaft; and means for supplying the aforesaid passage-ways with a gaseous or aeriform fluid.

2. Apparatus of the character indicated, comprising a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle has its lower end provided with a suitably-closed outlet; a pump having its inlet in open relation with the said vapor-outlet; means for heating the receptacle; an upright shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting and radially or approximately radially arranged arms which have passage-ways formed therein and extending longitudinally thereof, means for supporting the shaft; means for operating the shaft; and means for supplying the aforesaid passage-ways with a gaseous or aeriform fluid.

3. Apparatus of the character indicated, comprising a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; means for heating the receptacle; a shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting perforated arms having passage-ways formed therein and extending longitudinally thereof, which arms have orifices discharging into the receptacle; means for supporting the shaft; means for operating the shaft, and means for supplying the aforesaid passage-ways with a gaseous or aeriform fluid.

4. Apparatus of the character indicated, comprising a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle has its lower end provided with a suitably closed outlet; a pump having its inlet in open relation with the said vapor-outlet; means for heating the receptacle; a vertically-arranged shaft extending into and centrally of the receptacle and provided, within the receptacle, with laterally-projecting radially or approximately radially arranged perforated arms having passage-ways formed therein and extending longitudinally thereof; means for supporting the shaft; means for operating the shaft, and means for supplying the aforesaid passage-ways with a gaseous or aeriform fluid.

5. Apparatus of the character indicated, comprising the following a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, a shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting arms having passage-ways formed therein and extending longitudinally thereof, which arms have discharge-orifices; means for supporting the shaft; means for operating the shaft, and means for supplying air under pressure to the said passage-ways, substantially as and for the purpose set forth.

6. Apparatus of the character indicated comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle has its lower end provided with a suitably-closed outlet; a suction-creating device adapted, when operating, to create suction within the vapor-outlet; an upright shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting arms having passage-ways formed therein and extending longitudinally thereof, which arms have discharge-orifices; means for supporting the shaft; means for operating the shaft, and means for supplying air under pressure to the said passage-ways, substantially as and for the purpose set forth.

7. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle is provided, at its lower end, with a suitably-closed outlet; an upright shaft extending into the receptacle and provided, within the receptacle, with arms *l* projecting laterally of the shaft at or near the lower end of the shaft, which arms extend over and in close proximity to the bottom of the chamber of the receptacle, and are provided, respectively, with a scraper arranged to operate in close proximity to the said bottom; means for supporting the shaft, and means for rotating the shaft.

8. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle is provided, at its lower end, with a suitably-closed outlet; an upright shaft extending into the receptacle and provided, within the receptacle, with perforated hollow arms *l* projecting laterally of the shaft at or near the lower end of the shaft, which arms have discharge-orifices arranged to discharge downwardly against the bottom of the chamber of the receptacle; means for supplying fluid under pressure to the said arms; means for supporting the shaft, and means for rotating the shaft.

9. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, which receptacle is provided, at its lower end, with a suitably-closed outlet; an upright shaft extending into the receptacle and provided, within the receptacle, with perforated hollow arms *l* projecting laterally of the shaft at or near the lower end of the shaft, which arms have discharge-orifices arranged to discharge downwardly against the bottom of the chamber of the receptacle; means for supplying fluid under pressure to the said arms; guards upon the arms and overhanging the discharge-orifices of the said arms; means for supporting the shaft, and means for rotating the shaft.

10. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle and provided with a fluid-conducting passage-way formed in and extending longitudinally of the shaft, which shaft has radially or approximately radially arranged hollow arms at suitable intervals longitudinally of the shaft, with each of the said arms in direct communication, at its inner end, with the aforesaid passage-way; means for supplying the fluid to the said passage-way; means for supporting the shaft, and means for rotating the shaft.

11. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet, a shaft extending into the receptacle and provided with a fluid-conducting passage-way formed in and extending longitudinally of the shaft, which shaft has hollow perforated arms in open relation, interiorly, with the said passage-way; means for supplying air under pressure to the said passage-way; means for supporting the shaft, and means for operating the shaft.

12. Apparatus of the character indicated, comprising the following: a closed receptacle provided, at its upper end, with a suitably-closed charging-aperture and a vapor-outlet, which receptacle is provided, at its lower end, with a suitably-closed outlet; a suction-creating device adapted, when operating, to create suction in the vapor-outlet; an upright shaft arranged centrally of the receptacle and provided with a fluid-conducting passage-way formed in and extending longitudinally of the shaft, which shaft has hollow perforated arms in open relation interiorly with the said passage-way; means for supplying air under pressure to the said passage-way; means for supporting the shaft, and means for operating the shaft.

13. Apparatus of the character indicated, comprising a closed receptacle, a shaft extending into the receptacle and provided with a fluid-conducting passage-way formed in and extending longitudinally of the shaft, which shaft has hollow perforated arms projecting laterally of the shaft and in open relation interiorly with the aforesaid passage-way; a chest surrounding the shaft and having its chamber in open relation with the aforesaid passage-way; a valved pipe arranged to control the supply of fluid to the said chest; means for supporting the shaft, and means for rotating the shaft.

14. Apparatus of the character indicated comprising the following: a closed receptacle provided, at its upper end, with a suitably-closed charging-aperture and a vapor-outlet, which receptacle is provided, at its lower end, with a suitably-closed outlet; an upright shaft extending into the receptacle and provided with a fluid-conducting passage-way formed in and extending longitudinally of the shaft, which shaft has hollow perforated arms projecting laterally of the shaft and in open relation interiorly with the aforesaid passage-way; a chest surrounding the shaft outside of the receptacle and having its chamber in open relation with the aforesaid passage-way; a valved pipe arranged to control the supply of fluid to the said chest; means for supporting the shaft, and means for rotating the shaft.

15. Apparatus of the character indicated, comprising the following: a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; an upright shaft arranged within the receptacle and having a passage-way formed in and extending longitudinally of the shaft, which shaft is provided, within the receptacle, with laterally-projecting hollow imperforate arms arranged radially or approximately radially at intervals longitudinally of the shaft and in direct communication, at their inner ends, with the said passage-way; means for supplying a heating fluid to the said passage-way; means for supporting the shaft, and means for rotating the shaft.

16. Apparatus of the character indicated, comprising a receptacle; a shaft extending into the receptacle, and provided, within the receptacle, with laterally-projecting arms arranged a suitable distance apart and in pairs, with a web connecting together the outer ends of the arms of each pair of arms and provided with a scraper arranged to travel in close proximity to the surrounding wall of the chamber of the receptacle during the operation of the shaft.

17. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture, and a vapor-outlet; a shaft extending into the receptacle, and having a fluid-supply passage-way formed therein and extending longitudinally thereof, which shaft is provided, within the receptacle, with laterally-projecting hollow imperforate arms in open relation interiorly with the said passage-way; means for supplying the heating fluid to the said passage-way, and a valved exhaust passage-way formed in and extending longitudinally of the shaft and connected with the first-mentioned passage-way.

18. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle and provided, within the receptacle, with laterally-projecting hollow perforated arms; a compressed-air reservoir; a valved pipe leading from the said reservoir, and means for conducting air from the said pipe to the interior of the aforesaid arms.

19. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle and having a fluid-conducting passage-way 49 formed therein and extending longitudinally thereof, which shaft is provided, within the receptacle, with laterally-projecting hollow perforated arms in open relation interiorly with the said passage-way; a chest surrounding the shaft and having its chamber in open relation with said passage-way; a compressed-air reservoir, and a valved pipe leading from the said reservoir to and in open relation with the said chamber.

20. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle, and provided, within the receptacle, with laterally-projecting perforated arms arranged in pairs, with a web connecting together the outer ends of the arms of each pair of arms, and means for supplying fluid to the said arms.

21. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle, and provided, within the receptacle, with laterally-projecting perforated arms arranged in pairs, with a hollow web connecting together the outer ends of and establishing open relation between the arms of each pair of arms and having orifices arranged to discharge against the surrounding wall of the chamber of the receptacle, and means for supplying fluid to the said arms.

22. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a shaft extending into the receptacle and having a series of laterally-projecting hollow imperforate arms *z* and another series of laterally-projecting hollow perforated arms *y*; means for supplying a heating agent to the imperforate arms, and means for supplying air under pressure to the perforated arms.

23. In apparatus of the character indicated, a closed receptacle having a suitably-closed charging-aperture and a vapor-outlet; a suction-creating device adapted, when operating, to create suction in the vapor-outlet; means for draining the receptacle; a shaft extending into the receptacle and having a series of laterally-projecting hollow imperforate arms and another series of laterally-projecting hollow perforated arms, and means for supplying fluid to the said arms.

24. In apparatus of the character indicated, a receptacle provided, at its lower end, with a downwardly-discharging duct 17; a door normally closing the said duct from below; means for holding the door in its closed position, and a drain-pipe *f* comprising a pipe-section 31 attached to the door and in open relation with the aforesaid duct, another pipe-section 32 and a union 33 for coupling the said pipe-sections together.

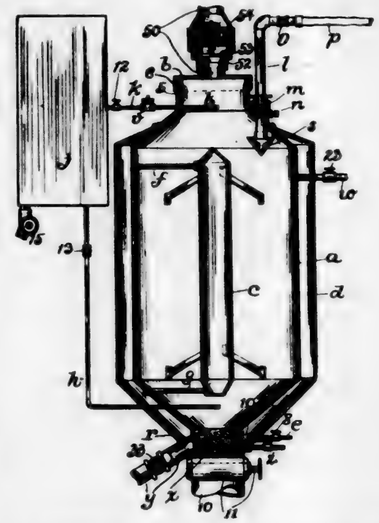
25. In apparatus of the character indicated, a receptacle provided, at its lower end, with a downwardly-discharging duct 17; a door normally closing the said duct from below; means for holding the door in its closed position; a strainer or screen at the inner side of the door and bulging upwardly, and a guard-forming frame extending over the said screen or strainer.

26. In apparatus of the character indicated, a closed receptacle having a downwardly-discharging duct 17; a door normally closing the said duct from below; means for holding the door in its closed position; a drain-pipe comprising a pipe-section attached to the door and in open relation with the aforesaid duct; a concave-convex strainer or screen at the inner side of the door and bulging upwardly, and a guard-forming frame *r* extending over the said screen or strainer.

707,566. PROCESS OF REDUCING OR RENDERING FISH OR OTHER MATERIAL. EUGENE R. ENGS, Cleveland, Ohio. Filed Mar. 20, 1902. Serial No. 99,130. (No specimens.)

Claim.—1. An improvement in obtaining a liquid product from material of the character indicated, comprising the heating of the material within a closed receptacle and placing and maintaining the material, during its treatment within the receptacle, under a pneumatic pressure greater than the pressure which results from the heating of the material, and, whenever the mass within the receptacle begins to cake or pack to such an extent as to materially retard the flow or liberation of the liquid product from the material, introducing, into the mass, air or aeriform fluid under a pressure greater than the first-mentioned pressure without interruption of the said first-mentioned pressure.

2. An improvement in obtaining a liquid product from material of the character indicated, comprising the heating of the material within a closed receptacle and subjecting the material, during its treatment within the receptacle, to a pneumatic pressure placed on top of the mass within the receptacle and greater than the pressure which results from the heating of the material, and, whenever the mass begins to cake or pack to such an extent as to materially retard the flow or liberation of the liquid product from the material, introducing, into the lower end of the receptacle, air or aeriform fluid under a pressure greater than the first-mentioned pneumatic pressure without interruption of the said first-mentioned pressure.



3. An improvement in obtaining a liquid product from material of the character indicated, comprising the heating of the material within a closed receptacle and placing and maintaining the material, during its treatment within the receptacle, under a pressure greater than the pressure which results from the heating of the material, and, whenever the mass within the receptacle begins to cake or pack to such an extent as to materially retard the flow or liberation of the liquid product from the material, introducing, into the mass, air or aeriform fluid under a pressure greater than the first-mentioned pressure, and relieving the receptacle of any pressure in excess of the said first-mentioned pressure.

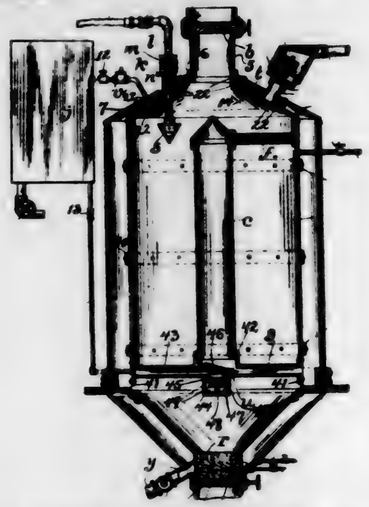
4. An improvement in obtaining a liquid product from material of the character indicated, comprising the heating of the material within a closed receptacle and subjecting the material, during its treatment within the receptacle, to a pressure placed on top of the mass within the receptacle and greater than the pressure which results from the heating of the material, and, whenever the mass begins to cake or pack to such an extent as to materially retard the flow or liberation of the liquid product from the material, introducing, into the lower portion of the receptacle, air or aeriform fluid under a pressure greater than the first-mentioned pressure, and relieving the receptacle, at the upper end thereof, of any pressure in excess of the aforesaid first-mentioned pressure.

707,567. RENDERING APPARATUS. EUGENE R. ENGS, Cleveland, Ohio. Filed Mar. 31, 1902. Serial No. 100,751. (No model.)

Claim.—1. In rendering apparatus, the combination, with a closed receptacle having a material-receiving inlet; means for heating the receptacle, and means for conducting the extracted liquid from the receptacle, of means for introducing, into the receptacle, a pneumatic pressure greater than the pressure which results from the heating of the material, and means for passing air or an aeriform body through the mass treated within the receptacle while the mass is acted upon by the aforesaid pneumatic pressure, substantially as and for the purpose set forth.

2. In rendering apparatus, the combination, with a closed receptacle having a material-receiving inlet; means for heating the receptacle, and means for conducting the extracted liquid from the receptacle, of means for maintaining, on top of the mass introduced into the receptacle, a pneumatic pressure greater than the pressure which results from the heating of the material, and means for passing air or an aeriform body upwardly through the mass treated within the receptacle while the mass is main-

tained under the aforesaid pneumatic pressure, substantially as and for the purpose set forth.



3. In rendering apparatus, the combination, with a closed receptacle having a material-receiving inlet; means for heating the receptacle, and means for conducting the extracted liquid from the receptacle, of means for maintaining, in the receptacle, a pneumatic pressure greater than the pressure which results from the heating of the material; means for introducing, into the lower portion of the receptacle, air or an aeriform body which is under a pressure greater than the aforesaid pneumatic pressure; an air-outlet extending from the upper portion of the chamber of the receptacle, a relief-valve normally closing the said outlet, and means acting to retain the said valve in its closed position and being powerful enough to prevent the said valve from being opened by the pneumatic pressure maintained within the receptacle as aforesaid, but adapted to yield upon an addition to the said last-mentioned pressure by the air or aeriform body introduced into the lower portion of the receptacle.

4. In rendering apparatus, the combination, with a closed receptacle having a material-receiving inlet; means for heating the receptacle, and means for conducting the extracted liquid from the receptacle, of a compressed-air reservoir externally of the aforesaid receptacle; a pipe in open relation with the said reservoir and discharging into the aforesaid receptacle; a pressure-regulating valve in the line of the said pipe, and means for affecting the passage of air or an aeriform body upwardly through the mass treated within the first-mentioned receptacle while the said mass is maintained under a pneumatic pressure conducted to the said receptacle by the aforesaid pipe, substantially as and for the purpose set forth.

5. In rendering apparatus, the combination, with a closed receptacle having a material-receiving inlet; means for heating the receptacle, and means for conducting the extracted liquid from the receptacle, of a compressed-air reservoir outside of the aforesaid receptacle; a pipe in open relation with the said reservoir and discharging into the upper portion of the aforesaid receptacle; a pressure-regulating valve in the line of the said pipe; a pipe in open relation with the compressed-air reservoir and discharging into the lower portion of the first-mentioned receptacle; a cut-off valve in the line of the last-mentioned pipe; an air-outlet connected with the upper portion of the chamber of the first-mentioned receptacle; a valve normally closing the said outlet, and means acting to retain the said last-mentioned valve in its closed position and just powerful enough to maintain the said valve closed against the pneumatic pressure maintained on the mass to prevent boiling of the most.

6. Rendering apparatus comprising a receptacle into which the material requiring treatment is placed; a heating-jacket surrounding the said receptacle; an annular section *f* interposed between and rigidly secured to the casings of the jacket and aforesaid receptacle at the upper end of the receptacle; a charging-pipe attached to the said annular section and in open relation, at its lower end, with the chamber of the aforesaid receptacle, a liquid-conducting pipe extending into the upper portion of the said receptacle, and a stuffing-box surrounding the said pipe and having its casing rigid with the aforesaid annular section.

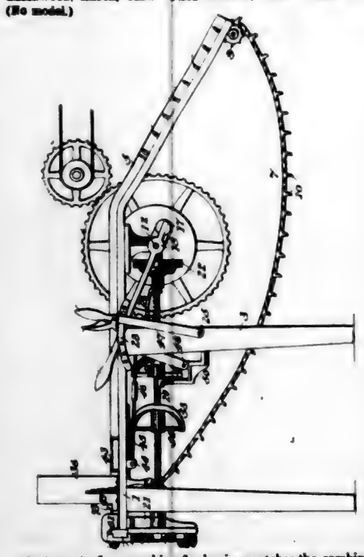
7. Rendering apparatus comprising a receptacle into which the material requiring treatment is placed; a heating-jacket surrounding the said receptacle; an annular section *f* interposed between and rigidly secured to the casings of the jacket and aforesaid receptacle at the upper end of the receptacle; a valved charging-pipe attached to the said annular section and in open relation, at its lower end, with the chamber of the aforesaid receptacle, and a pipe for conducting air under pressure into the upper portion of the chamber of the said receptacle and attached to the aforesaid annular section.

8. Rendering apparatus comprising a receptacle into which material requiring treatment is placed; a heating-jacket surrounding the said receptacle; means for conducting the heating agent into the chamber of the jacket; an upright heating-drum arranged centrally of the aforesaid receptacle; a head attached to the lower end of the drum and having a tubular arm communicating, at its inner end, with the chamber of the drum and in open relation, at its outer end, with the chamber of the jacket, which head is provided with another tubular arm adapted to conduct air or any aeriform body into the lower portion of the receptacle below the drum, and a pipe for conducting the air or other aeriform body into the last-mentioned arm.

9. Rendering apparatus comprising a receptacle into which material requiring treatment is placed; a heating-jacket surrounding the said receptacle; means for conducting the heating agent into the chamber of the jacket; an upright heating-drum arranged centrally of the aforesaid receptacle; a valved pipe for conducting air to the receptacle; a head attached to the lower end of the drum and having two tubular arms and a partition separating the passage-ways formed by the said arms, and one of the said arms establishing open relation between the chamber of the jacket and the chamber of the drum, and the other arm being in open relation with the aforesaid air-conducting pipe and arranged to conduct air into the lower portion of the aforesaid receptacle.

10. Rendering apparatus comprising a receptacle into which material requiring treatment is placed; a heating-jacket surrounding the said receptacle; means for conducting the heating agent into the chamber of the jacket; a valved pipe arranged to conduct air to the lower portion of the aforesaid receptacle; an upright heating-drum arranged centrally of the said receptacle and provided, at its lower end, with a head having two oppositely-arranged tubular arms and a partition separating the passage-ways formed by the said arms, which arms are attached to and reinforce the lower portion of the aforesaid receptacle, and one of the said arms establishing open relation between the chamber of the drum and the chamber of the jacket, and the other arm being in open relation with the aforesaid air-conducting pipe and arranged to conduct air into the aforesaid receptacle below the drum.

707,568. MACHINE FOR BOXING MATCHES. AUGUSTUS E. ELLERWOOD, Akron, Ohio. Filed Mar. 20, 1901. Serial No. 53,658. (No model.)



Claim.—1. In a machine for boxing matches the combination with a supporting-table, an intermittingly-moving means to convey drawers forward on said table, independent separate means for successively feeding cases downwardly on said table on either side of said first-named means, means to feed forward said cases on said table into alinement with the most advanced of said drawers, and a transversely-reciprocating slide to force said drawers into the cases, substantially as shown and described.

2. In a machine for boxing matches, the combination with a supporting-table, of a device for successively feeding cases alternately on opposite sides of said table, a carrier to intermittingly convey drawers into alinement with said cases, a reciprocating slide to alternately force the drawers severally into the cases, and mechanism for causing said parts to perform their respective functions, substantially as shown and described.

3. In a machine for boxing matches, the combination with a supporting-table, of a device for successively feeding cases alternately on opposite sides of said table, a carrier to intermittingly convey drawers into alinement with said cases, a reciprocating slide to alternately force the drawers severally into the cases, and abutment-blocks to support said cases against the thrust of the drawers, substantially as shown and described.

4. In a machine for boxing matches, the combination with a supporting-table having a device for successively feeding cases alternately on opposite sides of said table, and a carrier to intermittingly deliver drawers into alinement with said cases, a reciprocating slide to alternately push said drawers severally into said cases, abutment-blocks to support said cases against the thrust of the drawers, of a locking device for holding said abutment-blocks to receive said thrust, and devices connected with said slide to release said locking device, to permit the abutment-blocks to move with the slide, substantially as shown and described.

5. A machine for boxing matches, consisting of means to progressively feed forward filled drawers of matches, means to alternately force them to either side of their path and into cases therefor, means for feeding into suitable position said cases, substantially as shown and described.

6. In a machine for boxing matches, the combination with a supporting-table, openings in said table to permit the filled boxes to escape by gravitation, means to sustain cases over said openings to receive drawers, means to feed cases singly onto said supports, transversely-operating means to force alternate drawers into said cases and means to withdraw said supports from said cases when said drawers are within said cases, substantially as shown and described.

7. In a machine for boxing matches, the combination of devices to receive and progressively carry forward filled drawers of matches, means to carry forward empty cases for said drawers in a parallel line and on each side of said drawers, and a transversely-reciprocating plate to alternately force said drawers into alternate cases, substantially as shown and described.

8. In a machine for boxing matches, consisting of an endless traveling agent to convey drawers filled with matches intermittingly forward, means as a reciprocating transversely-moving carriage to cause said drawers to pass sidewise to the line of said endless traveling agent, means situated on either side of said traveling agent to convey cases for said drawers forward in a direction parallel to said traveling agent and devices on said carriage to cause said drawers to enter said cases.

9. A machine for boxing matches, consisting of an endless intermittingly traveling agent to carry drawers filled with matches progressively forward, means for storing, holding and retaining cases for said drawers independent means for feeding forward cases singly from said drawers o supply alternately, and means as a transversely-reciprocating carriage for forcing said drawers alternately in either direction into said cases, substantially as shown and described.

10. A machine for boxing matches consisting of a definite traveling agent to carry forward filled drawers of matches, mechanism as hoppers for holding supplies of cases for said drawers, independent, but definitely-actuated mechanism for removing cases, singly and alternately from each hopper, and means for causing said drawers to enter their respective cases, substantially as shown and described.

11. A machine for boxing matches consisting of a table, traveling means for feeding forward the drawers with a step-by-step motion, suitable means as hoppers arranged to hold supplies of cases therefor, means as reciprocating sliding blocks to remove cases singly from said hoppers and carry said cases forward into alinement with the most advanced of said drawers, and a reciprocating carriage moving transversely to the line of said advancing drawers to insert advancing drawers in said cases, substantially as shown and described.

12. A machine for boxing matches consisting of a definite traveling agent to carry forward filled drawers of matches, mechanism as hoppers for holding supplies of cases for said drawers, independent, but definitely-actuated mechanism for removing cases singly and alternately from each hopper, a shaft mounted in said machine, a double cam mounted thereon, mechanism as a sliding frame provided with spring-dogs to engage said agent and move it a definite distance arranged to be actuated by said cam, and means for causing said drawers to enter their respective cases, substantially as shown and described.

13. A machine for boxing matches consisting of a definite traveling agent to carry forward filled drawers of matches, mechanism as hoppers for holding supplies of cases for said drawers, means as projecting fingers for retaining temporarily said cases in said hoppers, independent but definitely-actuated mechanism for removing cases singly and alternately from each hopper consisting of divided blocks adapted to pass said fingers sliding in said machine, a shaft mounted therein, a double cam mounted on said shaft, a pair of rocking arms actuated by said cam alternately to reciprocate said blocks, and means for causing said drawers to enter their respective cases, substantially as shown and described.

14. In a machine for boxing matches, the combination of a supporting-table provided with openings for the escape of filled boxes of matches, a definite traveling agent to carry forward said filled boxes of matches, mechanism as hoppers for holding supplies of cases for said drawers, independent but definitely-actuated mechanism for removing cases singly and alternately from each hopper, means as projecting fingers to retain said cases in said hoppers temporarily, divided sliding blocks to clear said projecting fingers and having projecting fingers thereon to receive the cases as they descend and retain them over the openings in said table, means to reciprocate said blocks alternately, and transversely-reciprocating means for causing said drawers to enter their respective cases, substantially as shown and described.

15. A machine for boxing matches consisting of an endless traveling agent arranged to move at definite times and for definite spaces to cause drawers to feed forward singly, suitable means for storing, holding and retaining cases therefor consisting of two hoppers mounted in said machine provided with depending fingers to receive the lowest case in said hoppers, separate means for feeding forward cases singly from said sources of supply alternately and, means as a reciprocating carriage for forcing said drawers into said cases, substantially as shown and described.

16. A machine for boxing matches consisting of an endless traveling agent arranged to move at definite times and for definite spaces to cause drawers to feed forward singly, suitable means for storing, holding and retaining cases therefor, consisting of two hoppers mounted in said machine provided with cross-bars to prevent the escape of more than one case at a time, separate means for feeding forward cases singly from said sources of supply alternately and means as a reciprocating carriage for forcing said drawers into said cases, substantially as shown and described.

17. In a machine for boxing matches, the combination with a table having openings to permit the filled boxes to escape by gravitation, provided with movable supports to sustain cases to receive drawers, mechanism to feed cases singly onto said supports, consisting mechanism to force said drawers into said cases, means as a series of fingers resting temporarily above the openings in said table to hold said cases securely while said drawers are inserted in said cases, means to withdraw said supports when said drawers are completely within said cases, and means as slightly-reciprocating abutment-blocks to afford a stop to said cases during the insertion of said drawers, substantially as shown and described.

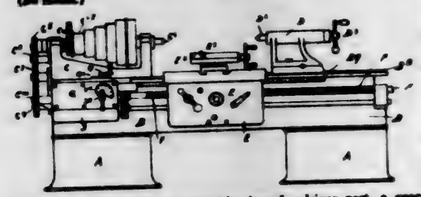
18. A machine for boxing matches consisting of a table, a traveling means for feeding forward the drawers with a step-by-step motion, suitable means as hoppers arranged to hold supplies of cases therefor, means as reciprocating sliding blocks to remove cases singly from said hoppers and carry said cases forward into alinement with the most advanced of said drawers, a shaft mounted in said machine bearing at one end a cam, a segmental gear mounted in said machine, a pair of rollers mounted in said gear, and adapted to be actuated by said cam, a reciprocating carriage operated by said gear, a projecting blade carried by said carriage arranged to force said drawers into said cases, substantially as shown and described.

19. A machine for boxing matches consisting of a table, a traveling means for feeding forward the drawers with a step-by-step motion, suitable means as hoppers arranged to hold supplies of cases therefor, means as reciprocating sliding blocks to remove cases singly from said hoppers and carry said cases forward into alinement with the most advanced of said drawers, a shaft mounted in said machine bearing at one end a cam, and at the other a device for changing the speed of said shaft, a segmental gear mounted in said machine, a pair of rollers mounted in said gear, and adapted to be actuated by said cam, a reciprocating carriage operated by said gear, a projecting blade carried by said carriage arranged to force said drawers into said cases, substantially as shown and described.

20. In a machine for boxing matches, the combination with a supporting-table of a device for successively feeding cases alternately on opposite sides of said table, a carrier to intermittingly convey drawers into alinement with said cases, and a reciprocating slide to alternately force the drawers severally into the cases, and abutment-blocks arranged to move in unison in either direction to force the case on one side inward and to carry, with the assistance of the reciprocating slide the case on the opposite side with its drawers outward over an opening in said table, substantially as shown and described.

21. In a machine for boxing matches, the combination with a supporting-table of a device for successively feeding cases alternately on opposite sides of said table, a carrier to intermittingly convey drawers into alinement with said cases, a reciprocating slide to alternately force the drawers severally into cases, and abutment-blocks to support said cases against the thrust of the drawers, said abutment-blocks arranged to simultaneously move in the same direction and arranged on one side to draw the cases inward upon suitable guides for directing the entrance of said drawers and on the other side to release the case on that side with its drawer from said guides and convey it over a suitable opening in said table, substantially as shown and described.

707,569. QUICK-FEED ARRANGEMENT FOR GEARS. WILLIAM T. BENDER, Cincinnati, Ohio. Filed Nov. 18, 1901. Serial No. 82,347. (No model.)



Claim.—1. In a lathe, the combination of a driven part, a gear-wheel, means connected with the source of power for rotating said gear-wheel, and means for enabling this gear-wheel to slide along on a line coincident with the axis of its revolution, a graduated disk and handle adapted to engage the graduations of the disk, means for enabling the movement of the handle to move said gear-wheel laterally, and a second graduated disk, means for causing the handle aforesaid to move said graduated disk, a swinging holder or box, a series of gear-wheels within this holder and adapted when the box is elevated to engage by one of its gears the first-named gear-wheel, and means for enabling the swinging box to be hoisted according to the graduations of the second graduated plate, a shaft on which the series of gears are located, this shaft being adapted when these gears are raised to operate the driven part, substantially as and for the purposes specified.

2. In a lathe, the combination of a driven part, a gear-wheel, means connected with the source of power and adapted to rotate said gear-wheel, a shaft on which this gear-wheel is slidable and with which it is rotatable, a graduated disk Q^2 and handle adapted to engage the graduations of the disk, a second disk with graduations, means adapted to give simultaneously to the said gear-wheel and the said disk a rectilinear and a rotatory motion respectively, a swinging holder or box, a series of gears supported thereby and adapted when the box is raised, to have one of its gears engage the first-named gear-wheel, and means for enabling the swinging box when elevated to engage the second disk in accordance with the graduations thereof, and support the series of gears, the shaft of said gears, means for communicating the motion of this shaft to the driven part, substantially as and for the purposes specified.

3. In a lathe, a shaft adapted to be operated by the power whereby the lathe is operated, a gear-wheel adapted to slide upon such shaft and to be rotated thereby, a handle and a graduated disk, adapted to engage the handle relatively to its graduations, a shaft rotatable by said handle, a gear-wheel on said shaft, a sliding rack adapted to be operated by said gear-wheel, a finger or projection on the rack, a projection in connection with the first-named gear-wheel adapted to engage such projection of the rack, and thus enable the sliding gear-wheel to be slid along its shaft, a swinging box or holder, a series of gears supported therein, that one of such gears which is opposite the sliding gear-wheel meshing with the latter when the swinging box or holder is raised, a latch connected to the swinging holder, a second plate, means connecting the handle-shaft aforementioned and the second plate, so that the rotation of the handle shall operate to move such plate relatively to the handle and to the movement of the sliding gear-wheel, and a series of means on the second plate for enabling the swinging holder to be latched thereto relatively to the rotation of said handle, and to the movement of said slidable gear-wheel, and to the amount of movement necessary for the swinging box to cause the desired gear of the swinging holder to mesh with the slidable gear-wheel, a driven part of the lathe and means between the gear of the swinging holder and the driven part for enabling said gear to operate such driven part, substantially as and for the purposes specified.

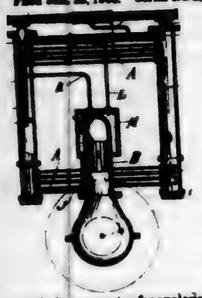
4. In a lathe, a shaft adapted to be operated by the power whereby the lathe is operated, a gear-wheel adapted to slide on such shaft and to be rotated thereby, a handle and a graduated disk, adapted to engage the handle relatively to its graduations, a shaft rotatable by said handle, a gear-wheel on said shaft, a sliding rack adapted to be operated by said gear-wheel, a finger or projection on the rack, a projection in connection with the first-named gear-wheel, adapted to engage such projection on the rack, and thus enable the sliding gear-wheel to be slid along its shaft, a miter-gear on the handle-shaft, a swinging box or holder, a series of gears supported therein, and that one thereof, when the swinging holder is lifted, which is opposite the slidable gear-wheel becoming ready for engagement with the slidable gear-wheel, a latch connected to the swinging holder, a miter gear-wheel meshing with the first-named miter-gear, a shaft on which the latter gear is carried, a second plate rotatable by this latter shaft, and a series of means on the second plate for engagement of the latch relative to the setting of the first-named handle, and the corresponding gear-wheel in the swinging holder, which latter gear-wheel, in that instance, engages the slidable gear-wheel, a driven part and means for enabling that gear-wheel of the series of gears in the holder to operate such driven part, substantially as and for the purposes specified.

5. In a lathe, the combination of a shaft H, suitable fixed supports in which this shaft is journaled, and the gear-wheel K adapted to slide thereon, a rod L parallel to shaft H, a sliding rod or sleeve M, the rack M^3 carried thereby, and in connection with the rack the shaft I^6, duly journaled, and the lever or handle Q carried thereby, a pin Q^2 on this handle, a graduated disk Q^3 with whose graduations the pin is adapted to engage, a gear-wheel P on the shaft I^6 and engaging the teeth of the rack M^3, a miter-gear I^5 on the shaft I^6, a shaft V^2, at an angle to the shaft I^6 and a miter-gear V thereon engaging the miter-gear I^5 of shaft I^6, a graduated plate V^3 adapted to be rotated by the shaft V^2, the swinging holder pivoted at S^2, shaft T^2, journaled in the swinging holder, and the set of cone-gears T, T^5, T^6, &c., on said shaft, and the gear T^{12} on the same shaft, the driven part, connections for enabling the gear T^{12} to rotate the driven part, means for lifting the swinging holder S and a latch S^3, S^{10}, for engaging any one of those graduations of the plate V^3 which is in position, having been set by the handle Q at the desired point on the graduated disk Q^3, substantially as and for the purposes specified.

6. In a lathe, the combination of a train of interchangeable gears C^5, C^7, &c., a shaft H, a gear-wheel slidable thereon, a rack M^3 slidable parallel to shaft H, a shaft I^6, a handle or lever carried thereby, and a gear engaging said rack, a miter-gear, a shaft V^2, a miter-gear thereon and engaging the first-named miter-gear, and a graduated plate V^3, adapted to be rotated by shaft V^2, a swinging holder, a set of cone-gears carried thereby, the shaft T^2, means for lifting the holder and for enabling the holder to be duly connected to the proper graduation of such plate, a gear (C^{10} on the shaft H, in connection with the said train of interchangeable gears C^5, C^7, &c., a driven part, means for enabling the mechanism aforedescribed to operate the driven part, substantially as and for the purposes specified.

7. In a lathe, a part to be driven, a swinging holder, a set of cone-gears therein, a shaft for said gears, means for enabling the part to be driven to be rotated by the said shaft, and a graduated plate as V^3 having graduations, and means on the swinging holder when raised to engage the desired one of those graduations, a shaft for rotating this disk, a shaft, a gear-wheel slidable thereon, a sliding finger or connection for sliding the gear-wheel, a lever, a shaft carrying this lever, and means for enabling the latter shaft to simultaneously operate both the sliding gear-wheel and the shaft operating the first-named graduated plate, by which connection with the box-holder is made, and a series of graduations for setting the lever aforesaid so that by the means mentioned, the proper gear in the swinging holder shall engage the slidable gear-wheel, substantially as and for the purposes specified.

707,570. WATER COOLING AND CIRCULATING APPARATUS FOR EXPLOSIVE-ENGINES. ERNEST BRYANT, South Hampstead, London, England. Filed Jan. 22, 1902. Serial No. 2,264. (No model.)



Claim.—Water-circulating apparatus for explosive-engines, comprising a series of water-circulating pipes above and below the cylinder-jacket opening into upright conduits one of which is blanked, a transverse conduit connecting the upper ends of said upright conduits and having a funnel-tube on one end passing into the lower part of the blanked upright conduit, with means for allowing the escape of surplus water and generated steam and for trapping the water carried by the steam, and pipes connecting the cylinder-jacket to the water circulating system, all arranged substantially in the manner and for the purpose hereinbefore described and illustrated in the accompanying drawings.

707,571. DUPLICATOR. ABRAHAM H. FISHER, Brooklyn, and CHARLES A. KENWORTHY, New York, N. Y. Filed Jan. 8, 1902. Serial No. 88,922. (No model.)

Claim.—1. In a duplicator, the combination with a box, of a duplicating-band the working portion of which extends substantially from end to end of said box and the remainder of which lies wholly below, and between the ends of, the working portion of said band, and means located between the ends of, and covered by, said working portion for supporting the band and for shifting the same to expose different working portions thereof.

2. In a duplicator, the combination with a box having a bed extending substantially from end to end thereof, of a duplicating-band the working portion of which rests on said bed and the remainder of which lies wholly below, and between the ends of, said bed, and means located between the ends of, and covered by, said bed for shifting said band to expose different working portions thereof.

3. In a duplicator, the combination with a box, of a duplicating-band the working portion of which extends substantially from end to end of said box and the remainder of which lies wholly below, and between the ends of, the working portion of said band, and band supporting and shifting means embodying delivery and take-up rollers also located below, and between the ends of and covered by, said working portion of said band.

4. In a duplicator, the combination with a box having a bed extending substantially from end to end thereof, of a duplicating-band the working portion of which rests on said bed and the remainder of which lies wholly below, and between the ends of, said bed, and delivery and take-up rollers disposed below, and between the ends of and covered by, said bed.

5. In a duplicator, the combination with a box having a hinged side section, of a bed extending substantially from end to end of said box, a duplicating-band the working portion of which lies on said bed and the remainder of which lies wholly below, and between the ends of, the working portion of said band, and a pair of band-supporting rollers between the ends of said bed one of which rollers is pivotally supported at one end in said side section.

6. In a duplicator, the combination with a box having a hinged side section and an adjacent hinged end section, of a bed extending substantially from end to end of said box, a duplicating-band the working portion of which rests on said bed and the remainder of which lies wholly below, and between the ends of, the working portion of said band, and a pair of band-supporting rollers between the ends of said bed one of which rollers is pivotally supported at one end in said side section.

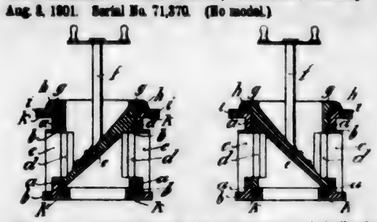
7. In a duplicator of the class specified, the combination with a box having at one side thereof a pair of hinged sections, of a duplicating-band the working portion of which extends substantially from end to end of said box, and band supporting and shifting means embodying delivery and take-up rollers each pivotally supported at one of its ends in one of said hinged sections.

8. In a duplicator, the combination with a box divided by partitions into three transverse compartments and having three hinged side sections for closing the ends of said compartments, of a duplicating-band the working portion of which extends substantially from end to end of said box, and band supporting and shifting means embodying delivery and take-up rollers each pivotally supported at one of its ends in one of said hinged sections.

9. In a duplicator, the combination with a box having a bed extending substantially from end to end thereof, of a pair of parallel guides rising from said bed at opposite sides thereof, a duplicating-band the working portion of which rests on said bed and fills the space between said guides and the remainder of which lies wholly below, and between the ends of, said bed, and means also located below said bed and between the ends thereof and covered thereby for shifting said band to expose different working portions thereof.

10. In a duplicator, the combination with a box having a hinged side section, of a bed extending substantially from end to end of said box, a duplicating-band the working portion of which rests on said bed and the remainder of which lies wholly below, and between the ends of, the working portion of said band, a pair of band-supporting rollers between the ends of said bed one of which rollers is pivotally supported at one end in said side section and also has at said end a ratchet-wheel, and a stop-pawl pivoted on said hinged section and coöperative with said ratchet-wheel.

707,572. REVERSING-VALVE FOR REGENERATIVE OR SIMILAR FURNACES. ALBERT FISCHER, Oberhausen, Germany. Filed Aug. 3, 1901. Serial No. 71,370. (No model.)

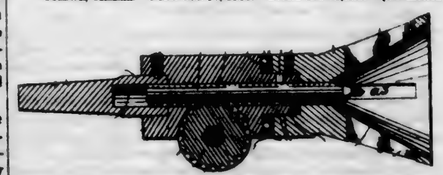


Claim.—1. A reversing-valve for regenerative and similar furnaces characterized by two cylinders *a b* arranged one to turn inside the other open at both ends and provided with openings *c d* opposite one another to and from the furnace, the inner *b* of which cylinders being divided into two parts by an inclined partition *e*, circular sand packings on the outer cylinder and lips on the inner cylinder working in the said sand packings.

2. A reversing-valve for regenerative and similar furnaces, comprising a cylinder *b* with a diagonal partition, valve-cheeks *m* partly surrounding the cylinder and made in two separate parts of fire-clay, and incasing plates *p q* holding the cheeks together in such a manner that they can be adjusted and pressed up against the cylinder *b* to form a good joint.

3. A reversing-valve for regenerative and similar furnaces, comprising an inner cylinder with openings and a diagonal partition, and an outer cylinder made of two divided plates *r* which are provided at the top and bottom with bent-in flanges and with sliding noses *w*, in front of the openings *d* in the inner cylinder *b*, for the inlet and outlet conduits, springs *x* tending to draw the two parts of the outer cylinder together.

707,578. CENTERING ATTACHMENT FOR LATHES. JOHN M. FLEMING, Ottawa, Canada, assignor of one-half to William Bothwell, Ottawa, Canada. Filed Oct. 17, 1901. Serial No. 78,969. (No model.)



Claim.—1. In combination, a body portion having a cylindrical extension at the front end, a cup-shaped portion having its rear end rotatably mounted on said cylindrical extension, a supporting-piece at the rear of said body portion, said cup-shaped portion, body portion and supporting-piece having an axial passage, a drill longitudinally movable in said passage, means for holding the same against rotary movement relative to the body, and means for advancing and retracting the drill substantially as described.

2. In combination, the body portion having a cylindrical extension at the front end with a circumferential groove formed thereon, a cup-shaped portion having its rear end rotatably mounted on said cylindrical extension, a key extending through the rear end of said cup-shaped portion and into said groove, a supporting-piece at the rear end of said body portion, said cup-shaped portion, body portion and supporting-piece having an axial passage, a drill longitudinally movable in said passage, means for holding the same against rotary movement relative to the body, and means for advancing and retracting the drill, substantially as described.

707,574. COMBINATION BRUSH AND COMB. CARL B. FLEMMING, Schönebeck, Germany. Filed June 26, 1901. Serial No. 66,073. (No model.)

Claim.—1. The combination with a hair-brush, of a comb secured to the same face of the back or handle of the brush as the bristles and extending about the body of the bristles adjacent the edge of the back.

2. The combination with a hair-brush, of a series of combs secured to the same face of the back or handle of the brush as the bristles and extending about the body of bristles adjacent the edge of the back and on parallel lines through said body of bristles, said combs acting to stiffen or limit the lateral movement of the free end of the bristles.

707,575. FEED-WATER HEATER. GOTTFRIED FLORACK, Düsseldorf, Germany. Filed Oct. 15, 1901. Serial No. 78,691. (No model.)

Claim.—1. A feed-water heater composed of a pair of cylindrical casings, a series of intervening radial partitions to form communicating water-passages, a steam-chamber inclosed by the inner casing, and a communicating steam-chamber surrounding the outer casing, substantially as specified.

2. A feed-water heater composed of a pair of cylindrical casings, a series of intervening radial partitions to form communicating water-passages, a steam-chamber inclosed by the inner casing, a communicating steam-chamber surrounding the outer casing, and ribs projecting from the casings into both of the steam-chambers, substantially as specified.

707,576. CHANNELING-MACHINE. ALFRED B. FOWLER, Central Falls, R. I., assignor, by mesne assignments, to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed June 19, 1897. Serial No. 641,495. (No model.)

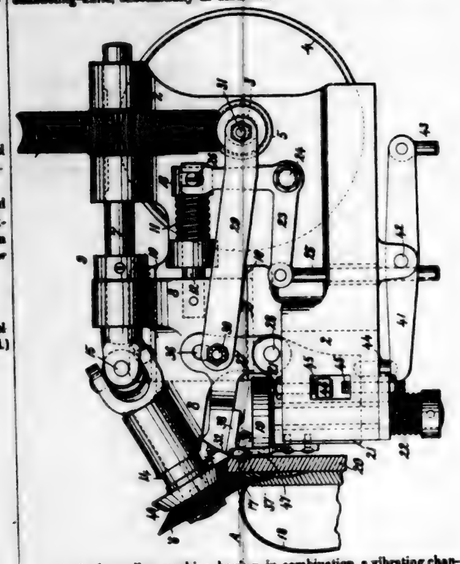
Claim.—1. A channeling-machine, having, in combination, a vibrating channeling-knife arranged to cut transversely to the line of feed and having a portion of its cutting edge oblique to the line of the feed and means for actuating said knife, substantially as described.

2. A channeling-machine, having, in combination, a vibrating channeling-knife arranged to cut transversely to the line of feed and having a portion of its cutting edge at an angle to the line of feed against which the work is forced by the action of the feed, means for actuating the knife and suitable feeding mechanism, substantially as described.

3. A channeling-machine, having, in combination, mechanism for continuously feeding the work, a vibrating channeling-knife arranged to cut transversely to the line of feed and having a cutting edge against which the work is forced by the action of the feed, and means for actuating the knife, substantially as described.

4. A channeling-machine, having, in combination, a vibrating channeling-knife arranged to cut transversely to the line of feed and obliquely to the surface of the work to form a continuous channel and lip, means for actuating the knife, and means for feeding the work, substantially as described.

5. A channeling-machine, having, in combination, a vibrating channeling-knife arranged to cut transversely to the line of feed and a lip-turning device in close proximity to and movable with said vibrating channeling-knife, substantially as described.



6. A channeling-machine, having, in combination, a vibrating channeling-knife, a vibrating lip-turning device following said knife to turn over the lip formed thereby, and means for actuating the knife and lip-turning device, substantially as described.

7. A channeling-machine, having, in combination, means for continuously feeding the work, a vibrating lip-turning device provided with a working face shaped to turn up the lip when forced against it by the feed, and means for actuating the lip-turning device, substantially as described.

8. A channeling-machine, having, in combination, a beveled feed-wheel arranged to enter the crease between the upper and welt, and an edge-gage consisting of a wheel mounted concentrically with the feed-wheel, substantially as described.

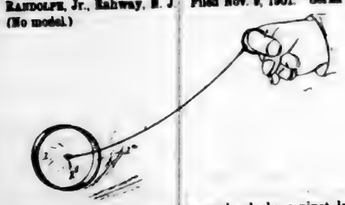
9. A channeling-machine, having, in combination, an oscillating channeling-knife, a channel-knife lever, and means for moving the fulcrum of the channel-knife lever during the operation of the machine to vary the position of the channel, substantially as described.

10. A channeling-machine, having, in combination, a vibrating channeling-knife arranged to cut transversely to the line of feed, and means for changing the path of movement of the knife during the operation of the machine, substantially as described.

11. A channeling-machine, having, in combination, a channeling-knife and feed mechanism comprising a shaft arranged to slide and rotate, a beveled feed-wheel engaging the crease between the upper and welt rotated by said shaft, means to rotate said shaft, and a spring acting to impart a sliding movement to said shaft and hold the feed-wheel in contact with the welt, substantially as described.

12. A channeling-machine, having, in combination, a vibrating channeling-knife, a vibrating lip-turning device, and means for actuating the knife and lip-turning device, substantially as described.

707,577. TOY. CHARLES H. FOX, East Orange, and WILLIAM H. RANDOLPH, Jr., Rahway, N. J. Filed Nov. 9, 1901. Serial No. 81,659. (No model.)



Claim.—A toy comprising an annular body, a pivot located in an opening at the axis thereof and having a head on one side of the body and an eye on the other side, the head and eye being adjacent to the body to limit the movement of the pivot in said opening, and a cord or the like connected with said eye on the side opposite the head whereby the cord is kept from being worn by the body, substantially as described.

707,578. GRAIN-DRILL SHOE. HENRY FUHR, Paris, Ill. Filed June 17, 1902. Serial No. 112,074. (No model.)

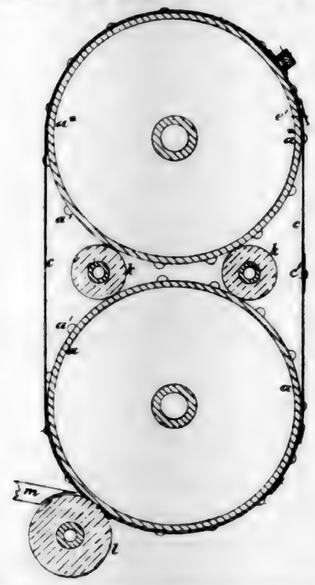
Claim.—1. In a grain-drill shoe, a runner provided with a grain-tube having an elbow at its lower or discharge end rearwardly faced, substantially as set forth.

2. In a grain-drill shoe, a runner, a grain-tube applied to the runner, and wings extended from the runner and arranged wholly above the delivery end of the grain-tube, substantially as set forth.

3. In a grain-drill shoe, a runner having its rear portion separated or spread, a grain-tube fitted in the space formed between the separated parts of the runner and having its lower end rearwardly extended, and wings projected rearwardly and upwardly from the runner and located wholly above the delivery end of the grain-tube, substantially as set forth.

4. In a grain-drill shoe, a runner comprising separated parts and integral wings projected upwardly and rearwardly from the separated parts, and a grain-tube fitted in the space between the separated parts of the runner and having its lower end rearwardly extended and located wholly below said wings, substantially as set forth.

707,579. STENCIL-PRINTING APPARATUS. DAVID GESTETNER, London, England. Filed July 16, 1901. Serial No. 68,536. (No model.)

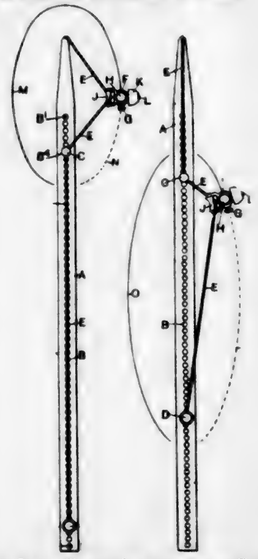


Claim.—1. In stencil-printing apparatus, the combination of two unperforated rollers mounted in a suitable framing, endless bands passed around said rollers, a porous sheet, such as yoshino paper, carried by said bands, a stencil, means for attaching one end of the stencil to the endless bands, ink-distributing rollers in contact with said main rollers and a pressure-roller arranged outside the stencil and porous sheet, substantially as set forth.

2. In stencil-printing apparatus, the combination of a frame, two main rollers mounted in said frame, means for rotating said main rollers, studs on said rollers, endless bands carried by said rollers, holes in said bands to engage with said studs, a fixed bar and a spring-bar carried by said bands, a sheet of porous material attached to said bars, a clamp carried by said bands to which one end of a stencil is attached, a pressure-roller arranged outside of the sheet of porous material, and ink-distributing rollers in contact with the main rollers, substantially as set forth.

3. In stencil-printing apparatus, the combination of a frame, two main rollers mounted in said frame, means for rotating said rollers, studs on said rollers, endless bands carried by said rollers, holes in said bands to engage the studs, spring-clips carried by said bands, a removable bar attached to the endless bands by said spring-clips, pins fixed to said bar, fastenings carried by said bands, a plain bar removably attached to said fastenings, springs connecting the plain bar with said fastenings, a sheet of porous material carried by the said bars, undercut projections attached to the endless bands, a stencil-carrying clamp attached to said undercut projections, ink-distributing rollers in contact with the main rollers, and a pressure-roller arranged outside of the sheet of porous material, substantially as set forth.

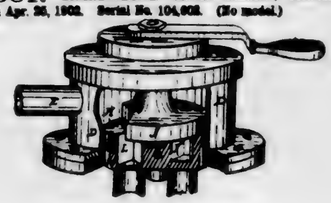
707,580. ELLIPSOGRAPH. DANIEL L. GREGORY, Chicago, Ill. Filed Nov. 13, 1901. Serial No. 82,127. (No model.)



Claim.—1. In an ellipsograph, a supporting-staff and a series of holes in the staff, pins adapted to removably engage said holes, and a guide-cord having one end attached to one end portion of the staff, and the other end portion of the cord attached to one of the pins, the intermediate portion of the cord engaging the other of the pins, and a tool slidingly mounted on the cord, for the purpose stated.

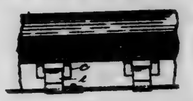
2. In an ellipsograph, a supporting-staff and a guide-cord, the latter adjustably attached to the staff, a tool-holder and a roller pivotally mounted thereon, the guide-cord in engagement with the roller, the roller so disposed relative to the guide-cord that the latter subtends an angle to plane of revolution of the roller and spirally contacts the latter, in the manner and for the purpose stated.

707,581. BRAKE-VALVE. GEORGE GREGORY, Colwich, Iowa. Filed Apr. 26, 1902. Serial No. 104,602. (No model.)



Claim.—In a device for operating air-brakes, a valve provided with a recess on its under side and set in a casing, a valve-seat having three ports, one to furnish air direct to operate the tender and engine brakes, a port to operate the automatic air-brakes of the train and the third for exhaust, and a lever for rotating the valve to utilize the ports simultaneously for operating the brakes on the tender and engine, and the automatic train-brakes.

707,582. VEHICLE-TIRE. WALTER I. GRISCOM, Springfield Mass. Filed Jan. 18, 1901. Serial No. 43,667. (No model.)



Claim.—1. In a vehicle-wheel, in combination with the rim, a ribbon encircling the rim and secured thereto, a tire, ribbon-attaching loops and clips adapted to secure the tire to the ribbon.

2. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon adapted to be secured in said groove, a tire, and attaching loops and clips securing the tire to the ribbon.

3. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon arranged to be secured within the groove, attaching-clips secured by the ribbon, the tire, and attaching-loops secured to the tire and adapted to be engaged with said clips.

4. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon having each of its meeting ends bent at an angle to the plane of the ribbon, a socket-piece consisting of a flat piece of metal embracing the body part of the ribbon and having a slot adapted to receive each of said bent ends of the ribbon, a tire, and means for securing the tire to the ribbon.

5. In a wheel, in combination with the rim having a peripheral groove, a ribbon having its ends bent to receive a socket-piece, the socket-piece adapted to secure the ribbon within the groove, a tire, attaching-loops secured to the tire, and attaching-clips passing underneath the ribbon and in engagement with the attaching-loops

6. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon adapted to be secured within said groove, a tire, attaching-loops secured to the tire, and clips passing underneath the ribbon and engaging with the loops at a point within the groove in the rim.

7. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon adapted to be secured within said groove, a tire, attaching-loops embedded within the tire and projecting on each side, and attaching-clips passing underneath the ribbon and in engagement with the ends of said loops.

8. In a vehicle-wheel, in combination with the rim having a peripheral groove, a tire having a broad end tread overlying the edges of the groove and a base of a width less than the width of the groove, a ribbon adapted to be secured within the groove and underneath the tire, and means for securing the tire to said ribbon.

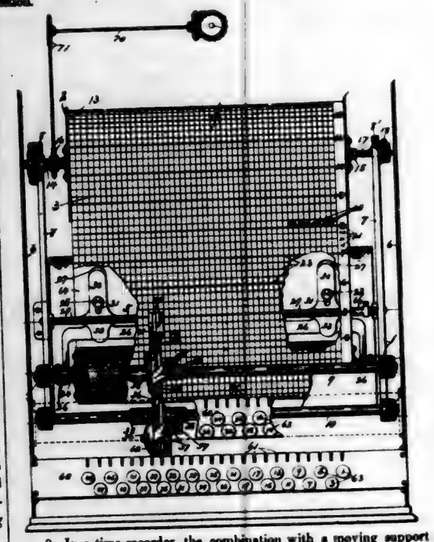
9. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon adapted to be secured within said groove, a tire of elastic material having one or more layers of textile fabric embedded in and near the tread portion of the tire, and clips and loops adapted to secure the ribbon and tire together.

10. In a vehicle-wheel, in combination with the rim having a peripheral groove, a ribbon having each of its meeting ends bent at an angle to the plane of the ribbon, a socket-piece consisting of a flat piece of metal having its ends bent over opposite edges of the ribbon and containing slots each of which receives the two bent ends of said ribbon, a tire, and means for securing the tire to the ribbon.

707,583. TIME-RECORDER. THOMAS D. GREER, Syracuse, N. Y. Filed Apr. 6, 1901. Serial No. 54,631. (No model.)

Claim.—1. In a time-recorder the combination with a grooved platen of revolving rollers carrying a record-sheet movable across the groove of the platen, means for rotating one of the rollers, a vertically-movable yoke supporting the other roller and mounted on the platen, a head movable lengthwise of the platen, independently-movable handpieces mounted on the head, a puncturing-pin alined with the groove of the platen and adapted to puncture the record-sheet and a single pawl carried by the head and actuated by either of the handpieces for operating the puncturing-pin.

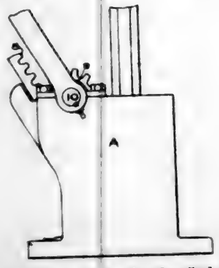
2. In a time-recorder, the combination with an inclosing case having substantially parallel slots and a series of employee designating characters for each slot, a revolving feed-roll carrying a record-sheet, a platen, a sliding head having handpieces pivoted thereto and projecting through said slots, a puncturing-pin registered with the platen and adapted to puncture the record-sheet, and a single pawl adapted to be actuated by either of the handpieces for forcing the puncturing-pin to its operating position.



3. In a time-recorder, the combination with a moving support for the record-sheet, a fixed platen of a puncturing or marking device consisting of a rock-arm having a puncturing or marking point, a manually-operated pawl for engaging and moving said arm to its operative position and means whereby the continued movement of the pawl releases it from engagement with the arm after the puncturing-point has been moved to its operative position.

4. In a time-recorder, the combination with an inclosing case, of a platen having employee-designating characters and recesses corresponding with said characters, a revolving feed-roll having an endless record-sheet mounted thereon and depending therefrom, an idler suspended within and upon the depending loop of the record-sheet, said record-sheet being provided with lengthwise and transverse divisions, the lengthwise divisions corresponding to the characters on the plate and the transverse divisions representing intervals of time, a fixed platen transverse of the record-sheet between the roll and idlers, a transverse bar parallel with the plate, a head mounted on and movable lengthwise of the said bar, a single movable member mounted on the head and provided with a puncturing-pin for puncturing the record-sheet between the feed-roll and idler, a pawl detachably engaged with said member for forcing the same to its operative position and a plurality of handpieces also mounted on the head for operating the pawl, and means for forcing the pawl out of engagement with said member as the pawl is moved to its operative position.

707,584. DRILL-SHAPER. DAN GREENWALT and JAMES B. DAWSON, Breckenridge, Colo. Filed Nov. 11, 1901. Serial No. 81,836. (No model.)



Claim.—1. In a machine of the class described, the combination of suitable framework provided with a vertical drill-opening arranged to admit a drill from the top thereof, a bed-plate at the bottom of said opening, a knife arranged at an angle with said opening, and means for actuating said knife.

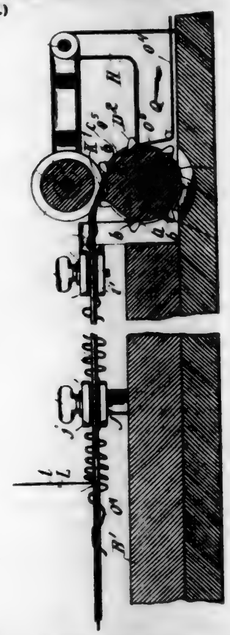
2. In a machine of the class described, the combination with suitable framework provided with a vertical drill-opening arranged to admit a drill from the top thereof, a knife slidably supported at an angle therewith, and provided with a rack, roller-bearings supporting said knife, a pinion intermeshing with said rack, and an actuating-handle for said pinion.

3. In a machine of the class described, the combination of suitable framework provided with a vertical drill-opening, and a horizontal opening at the lower end of said vertical opening, a bed-plate slidable in said horizontal opening, a lug arranged in said opening, an arm hinged to said bed-plate and having notches interlocking with said lug, a knife slidable at an angle with said drill-opening, and means for actuating said knife

4. The combination in a drill-shaper in which a drill is held in vertical position, a horizontally-slidable bed-plate provided with an inclined abutting wall for the bit end of the drill, means for holding said bed-plate in adjusted position, an upwardly-inclined knife provided with a rack, roller-bearings for said knife, a pinion engaging with the rack-teeth upon said knife, and an actuating-lever for said pinion.

5. The combination in a drill-shaper in which a drill is held in upright position, an adjustable bed-plate provided with an inclined abutting wall for the bit end of said drill, a knife, and means for moving said knife toward and from said bed-plate.

707,585. MACHINE FOR THREADING TAPE INTO EDGINGS. DAVID GROTTA, Newark, N. J., assignor to Weingarten Bros., a copartnership composed of Levi Weingarten, Oscar Weingarten, and David Weingarten, New York, N. Y. Filed Aug. 1, 1901. Serial No. 70,451. (No model.)



Claim.—1. As an article of manufacture, a roller adapted to be used in a machine for passing ribbon through insertion, said roller having a series of spurs or sprockets thereon, said spurs being slotted and having an incline or cam-surface at the bottom of each slot.

2. As an article of manufacture, a roller adapted to be used in a machine for passing ribbon through insertion, said roller having a groove around the periphery thereof, a series of spurs in the groove projecting beyond the periphery of the roller and having longitudinal slots therein, a cam or incline at the bottom of each slot.

3. As an article of manufacture, a roller adapted to be used in a machine for passing ribbon through insertion, said roller having a groove around the periphery thereof, a series of spurs in the groove at equal distances apart projecting beyond the periphery of the roller and having slots therein, and a cam or incline at the bottom of each slot.

4. In a machine for passing ribbon through insertion, a roller having spurs thereon adapted to enter every other hole in the insertion through which the ribbon is to pass, a needle carrying a ribbon, and means for vibrating the needle so that it may enter one of said holes from one side of the insertion and pass through the next hole from the other side of the insertion.

5. In a machine for passing ribbon through insertion, a roller having a groove around the periphery thereof, a series of spurs in the groove adapted to enter every other hole in the insertion through which the ribbon is to pass, each spur projecting beyond the periphery of the roller and having a slot therein, a cam or incline at the bottom of the slot, a needle the end of which rests in the bottom of the groove and adapted to be raised by a cam so that the needle is vibrated to enter one of the openings in the insertion from one side thereof and the next opening from the other side as the roller rotates.

6. In a machine for passing ribbon through insertion, a roller having a groove around the periphery thereof, a series of spurs in the groove adapted to enter every other hole in the insertion through which the ribbon is to pass, each spur projecting beyond the periphery of the roller and having a slot therein, a cam or incline at the bottom of the slot, a needle the end of which rests in the bottom of the groove and adapted to be raised by a cam so that the needle is vibrated to enter one of the openings in the insertion from one side thereof and the next opening from the other side as the roller rotates, and a guide-roll above the roller.

7. In a machine for passing ribbon through insertion, a roller having a groove around the periphery thereof, a series of spurs in the groove adapted to enter every other hole in the insertion through which the ribbon is to pass, each spur projecting beyond the periphery of the roller and having a slot therein, a cam or incline at the bottom of the slot, a needle the end of which rests in the bottom of the groove and adapted to be raised by a cam so that the needle is vibrated to enter one of the openings in the insertion from one side thereof and the next opening from the other side as the roller rotates, a guide-roll above the said roller adapted to bear upon the surface of the insertion when passing through the machine and having a groove around the periphery thereof through which the spurs pass.

8. In a machine for passing ribbon through insertion, a roller having a groove around the periphery thereof, a series of spurs in the groove adapted to enter every other hole in the insertion through which the ribbon is to pass, each spur projecting beyond the periphery of the roller and having a slot therein, a cam or incline at the bottom of the slot, a needle the end of which rests in the bottom of the groove and adapted to be raised by a cam so that the needle is vibrated to enter one of the openings in the insertion from one side thereof and the next opening from the other side as the roller rotates, a pivoted frame, a guide-roll mounted in the frame and adapted to bear upon the upper surface of the insertion when passing through the machine and having a circular groove around the periphery thereof through which the needle and the spurs pass.

9. In a machine for passing ribbon through insertion, a roller having a circular groove around the periphery thereof, spurs projecting from said groove at equal distances apart, each spur being slotted, a cam or incline at the bottom of each slot, a pivoted clamp, a needle carried by said clamp and resting in the bottom of the groove at its lowest position, means for rotating the roller so that the cam will pass under the needle to raise its end and permit said end to pass through that opening of the insertion through which the spurs pass, and then lowered to pass through the next opening in the insertion from the opposite direction.

10. In a machine for passing ribbon through insertion, a roller having a circular groove around the periphery thereof, spurs at equal distances apart projecting from said groove beyond the periphery of the roller, each of said spurs having a slot therein, a cam-surface at the bottom of the slot, clamps for holding a needle, one of the clamps being pivoted to permit the vibration of the end of the needle, a needle, the end of which rests at the bottom of the groove and adapted to be raised by the cam-surface in the slot, as and for the purpose specified.

11. In a machine for passing ribbon through insertion, a roller having a circular groove around the periphery thereof, spurs at equal distances apart projecting from said groove beyond the periphery of the roller, each of said spurs having a slot therein, a cam-surface at the bottom of the slot, clamps for holding a needle, one of the clamps being pivoted to permit the vibration of the end of the needle, a needle, the end of which rests at the bottom of the groove and adapted to be raised by the cam-surface in the slot, and a guide-roll above the said roller and adapted to bear upon the upper surface of the insertion as it passes through the roll, as and for the purpose specified.

12. In a machine for passing ribbon through insertion, a roller having a circular groove around the periphery thereof, spurs at equal distances apart projecting from said groove beyond the periphery of the roller, each of said spurs having a slot therein, a cam-surface at the bottom of the slot, clamps for holding a needle, one of the clamps being pivoted to permit the vibration of the end of the needle, a needle, the end of which rests at the bottom of the groove and adapted to be raised by the cam-surface in the slot, a guide-roll having a circular groove around the pe-

riphery thereof through which pass the needle and the spurs, and a pivoted frame carrying said roll, as and for the purpose specified.

13. In a machine for passing ribbon through insertion, a supply-roll adapted to carry insertion to be operated upon, a roller having a circular groove around the periphery thereof, spurs projecting at equal distances apart from the groove and above the circumference of the roller, each spur having a slot therein and adapted to enter every other opening in the insertion through which the ribbon is to be passed, an incline or cam at the bottom of each slot, means for guiding the insertion to the roll, clamps, one of which is pivoted, a hollow needle, having a slot therein, carried by said clamps, the end of which rests in the bottom of the groove of the roller and is adapted to be raised by the cam in the spurs, a guide-roll having a circular groove around the periphery thereof and in which the spurs and needle enter when the roller is in its lowered position, a pivoted frame carrying said guide-roll, a ribbon-spool adapted to feed the ribbon through the slot in the hollow needle, a take-up roll adapted to receive and take up the insertion and ribbon as they come from the needle, substantially as described.

14. In a machine for passing ribbon through insertion, a supply roll adapted to carry insertion, a feed-roller having spurs thereon adapted to enter every other opening in the insertion through which the ribbon is to be passed, means for guiding the insertion to said roller, a vibrating needle, means for raising and lowering the needle to permit it to pass through one of the openings in the insertion from one side thereof and to enter the next opening through the other side thereof, a take-up roll, and means for permitting the ribbon to pass through the insertion while on the needle, substantially as and for the purpose described.

15. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a roll, spurs on said roll with which the point of said needle is in sliding engagement, said spurs being constructed to alternately raise and lower the point of the needle, substantially as and for the purpose set forth.

16. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a roll, cams or inclines on said roll with which the point of the needle is in sliding engagement, said cams or inclines being constructed to alternately raise and lower the point of the needle, and means on said roll for feeding the lace or insertion upon said needle, and causing it to be gathered upon the needle, substantially as and for the purpose set forth.

17. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a roll, cams or inclines on said roll with which the point of the needle is in sliding engagement, said cams or inclines being constructed to alternately raise and lower the point of the needle, and spurs or sprockets on said roll adapted to enter the openings of said insertion and feed the same upon the needle, and to be gathered on said needle, substantially as and for the purpose set forth.

18. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a roll, spurs or sprockets on said roll adapted to enter the openings of said insertion, said sprockets or spurs being provided with cams or inclines with which the end of the needle is brought into sliding engagement to cause said end of the needle to enter the openings of the lace or insertion and gather the same upon the needle, substantially as and for the purpose set forth.

19. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a roll, cams or inclines on said roll with which the point of the needle is in sliding engagement, said inclines being constructed to alternately raise and lower the point of the needle, and an upper roll bearing upon said first-named roll, said upper roll being provided with an annular groove, and means on said first-mentioned roll extending into the groove on said upper roll for feeding the meshes of the lace upon said needle and causing the insertion to be gathered on said needle, substantially as and for the purpose set forth.

20. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a lower roll, cams or inclines on said roll with which the point of the needle is in sliding engagement, said inclines being constructed to alternately raise and lower the point of the needle, and an upper roll bearing upon the lower roll, said upper roll being provided with an annular groove, and sprockets on said lower roll extending into the groove on said upper roll and adapted to enter the openings of the insertion and feed the lace upon the needle and causing the insertion to be gathered on said needle, substantially as and for the purpose set forth.

21. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a lower feed-roll, cams or inclines on said roll with which the point of the needle is in sliding engagement, said cams or inclines being constructed to alternately raise and lower the point of the needle, and an upper feed-roll bearing upon the said lower roll, said upper roll being provided with an annular groove and sprockets or spurs on said roll extending into the groove on said upper roll and adapted to enter the openings of the insertion and feed the insertion upon the needle, and to be gathered on said needle, substantially as and for the purpose set forth.

22. In a machine for passing ribbon through insertion or lace, the combination with a needle, of a lower feed-roll and an upper feed-roll bearing upon the said lower roll, said upper roll being provided with an annular groove, and spurs or sprockets on said roll extending into the annular groove in said upper roll, said spurs being provided with a curved surface with which the end of the needle is brought in sliding engagement to cause said needle to enter the openings of the insertion and gather it upon the needle, substantially as and for the purpose set forth.

23. In a machine for passing ribbon through insertionor lace, the combination with a base provided with a support and a needle in said support, of a second support, having bearings, a lower roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper feed-roll in said frame provided with an annular groove, and means on said lower roll extending into the groove in said upper roll for feeding the insertion upon said needle, and causing the insertion to be gathered upon the needle, substantially as and for the purpose set forth.

24. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a second support, having bearings, a roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper feed-roll in said frame provided with an annular groove, and sprockets or spurs on said lower roll extending into the groove in said upper roll and adapted to enter the openings of said insertion and feeding the insertion upon the needle, and to be gathered on said needle, substantially as and for the purpose set forth.

25. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a second support, having bearings, a lower roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper feed-roll in said frame provided with an annular groove, and sprockets or spurs on said lower roll extending into the groove in said upper roll, said sprockets having inclined surfaces with which the end of the needle is brought in sliding engagement to cause said end of the needle to enter the openings and gather the same upon the needle, substantially as and for the purpose set forth.

26. In a machine for passing ribbon through insertion or lace, the combination of a base provided with a support and a needle in said support, of a guide and a roll on said base, cams or inclines on said roll with which the point of the needle is in sliding engagement, and said inclines being constructed to alternately raise and lower the end of the needle, and means on said roll for feeding the openings of the insertion upon said needle, and causing it to be gathered upon the needle, substantially as and for the purpose set forth.

27. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a guide and a roll on said base, cams or inclines on said roll with which the point of said needle is in sliding engagement, said inclines being constructed to alternately raise and lower the point of the needle, and spurs or sprockets on said roll adapted to enter the openings of said insertion and feed it upon the needle, and cause it to be gathered upon the needle, substantially as and for the purpose set forth.

28. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a guide and a roll on said base and sprockets or spurs on said roll adapted to enter the openings of said insertion, said spurs being provided with an incline having surfaces with which the end of the needle is brought in sliding engagement to cause said end of the needle to enter the openings of the insertion, and cause the insertion to be gathered upon the needle, substantially as and for the purpose set forth.

29. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a guide on said base, a second support having bearings, a lower roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper roll in said frame provided with an annular groove, and means on said lower roll extending into the groove in said upper roll for feeding the openings of the insertion upon said needle, and causing the insertion to be gathered upon the needle, substantially as and for the purpose set forth.

30. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a guide on said base, a second support having bearings, a lower roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper roll in said frame provided with an annular groove and sprockets or spurs on said lower roll extending into the groove in said upper roll and adapted to enter the openings of said insertion and feed it upon the needle, and cause it to be gathered upon the needle, substantially as and for the purpose set forth.

31. In a machine for passing ribbon through insertion or lace, the combination with a base provided with a support and a needle in said support, of a guide on said base, a second support having bearings, a lower roll rotatively arranged in one of said bearings, and a frame pivotally connected with a spindle in another of said bearings, an upper roll in said frame provided with an annular groove, and sprockets or spurs on said lower roll extending into the groove in said upper roll, said sprockets being provided with inclines having surfaces with which the end of the needle is brought in sliding engagement to cause said end of the needle to enter the openings of the insertion, and gather the same upon the needle, substantially as and for the purpose set forth.

32. In a machine for passing ribbon through insertion or lace, the combination with a roll, cams or inclines on said roll, of a needle having its pointed end in sliding engagement with said inclines, said inclines being constructed to alternately raise and lower the point of said needle and thereby gather the insertion upon said needle, substantially as and for the purpose set forth.

33. In a machine for passing ribbon through insertion or lace, the combination with a base, of a support provided with a pair of holding-jaws, a needle detachably secured between said jaws, means on said base for feeding and gathering insertion upon said needle, a second support on said base having a bearing and a holding clamp or dog provided with jaws adapted to grasp the end of the needle, substantially as and for the purpose set forth.

34. In a machine for passing ribbon through insertion or lace, the combination with a needle and means for feeding and gathering insertion upon said needle, of a support having a bearing, a holding-clamp in said bearing provided with jaws, and means for fixing said jaws about the needle, substantially as and for the purpose set forth.

35. In a machine for passing ribbon through insertion or lace, a roll, cams or inclines on said roll, and means cooperating with said cams or inclines for picking up and gathering the insertion, substantially as and for the purpose set forth.

36. In a machine for passing ribbon through insertion or lace, the combination, with a base, of a support provided with a pair of holding-jaws, a needle detachably secured near one end between said jaws, means on said base for feeding and gathering lace upon said needle, a second support upon said base having a bearing, and a movable holding-dog arranged in said bearing provided with holding-jaws adapted to grasp the gathering end of the needle, substantially as and for the purpose set forth.

37. In a machine for passing ribbon through insertion or lace, the combination, with a base, of a support provided with a pair of holding-jaws, a needle detachably secured near the rear end between said jaws, means on said base for feeding and gathering the lace upon the said needle, a second support on said base having a bearing, and a holding-dog pivotally arranged in said bearing provided with holding-jaws adapted to grasp the gathering end of the needle, substantially as and for the purpose set forth.

38. In a machine for passing ribbon through insertion or lace, the combination, with a needle and means for feeding and gathering lace upon said needle, of a support having a bearing, a movable holding-dog arranged in said bearing provided with holding-jaws, and means for fixing said jaws about the needle, substantially as and for the purpose set forth.

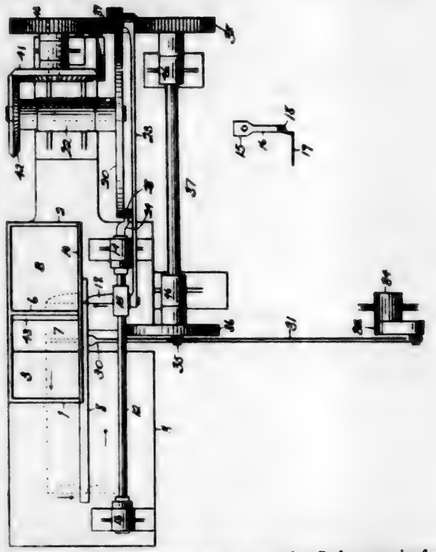
39. In a machine for passing ribbon through insertion or lace, the combination, with a needle and means for feeding and gathering lace upon said needle, of a support having a bearing, a holding-dog pivotally arranged within said bearing provided with holding-jaws, and means for fixing said jaws about the needle, substantially as and for the purpose set forth.

40. In a machine for passing ribbon through insertion or lace, the combination, with a feed-roll having feed-sprockets arranged with spaces between them, inclines or cams between said sprockets provided with curved surfaces, of a needle having a curved end in sliding engagement with said curved surfaces of said inclines, as and for the purpose set forth.

707,586. METAL FENCE-POST. CHARLES C. HAGERMAN, Marion, Iowa, assignor to Hagerman & Williams, Marion, Iowa, a firm composed of Charles C. Hagerman and Benjamin R. Williams. Filed Apr. 12, 1902. Serial No. 102,680. (No model.)

Claim.—A fence-post comprising a central plate having wings at its side edges lying at obtuse angles thereto, said plate having a longitudinal slot, a wire-clamping hook having a threaded stem passed through the slot and between the wings, a malleable washer disposed upon the stem and having a diameter greater than the width of the central plate, and a nut screwed upon the stem and adapted to impinge the washer and bend the latter against the edges of the nut to prevent unscrewing thereof, and to draw the stem through the slot.

707,587. INSERTING-MACHINE FOR NEWSPAPERS. SAMUEL R. HAYDEN, Kansas City, Mo., assignor to Anthony L. Clark and Charles W. Lake, Kansas City, Mo. Filed Feb. 13, 1902. Serial No. 93,985. (No model.)



Claim.—1. In a machine for the purpose described, a magazine for inner sections, an adjacent magazine 1 for outer sections, and a reciprocating blade, and means for inserting said blade between the folds of an inner section and then moving said blade so as to insert said inner section between the folds of an outer section, substantially as described.

2. In a machine for the purpose described, a magazine 2 for inner sections, an adjacent magazine 1 for outer sections, a rock-shaft, a cross-head mounted slidably and non-rotatably on said rock-shaft, a horizontal inserter-blade connected pivotally to said cross-head, and means for reciprocating said cross-head and rocking said rock-shaft, whereby said inserter-blade is inserted into said magazine 2 between the folds of an inner section, is then moved into said magazine 1, pulling after it said inner section and inserting it into an outer section, is then withdrawn from said inner section, and is then returned to starting position, ready to be inserted into another inner section, substantially as described.

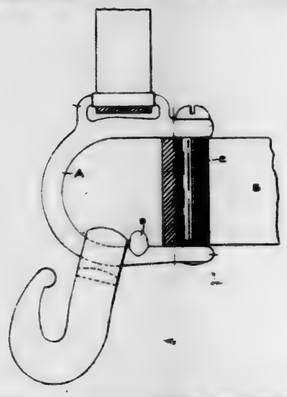
3. In a machine for the purpose described, a magazine 1 for outer sections, a magazine 2 for inner sections, an oscillating finger for depressing the lower fold of each outer section, a reciprocating blade, and means for inserting said blade between the folds of an inner section and then moving said blade so as to insert said inner section between the folds of said outer section; substantially as described.

4. In a machine for the purpose described, a magazine 1 for outer sections, a magazine 2 for inner sections, the bottom of said magazine 1 having an opening and a shelf therein, a guide-bar secured to said magazines as shown, and having a longitudinal slit therein, a rock-shaft having a crank on one end thereof, a cross-head mounted slidably and non-rotatably on said rock shaft, an inserter-blade connected pivotally to said cross-head and projecting into or through said slit in said guide-bar, a wheel, a pair of cam-lips 28, 29, on said wheel, an opening adjacent to each of said cam-lips, and a pitman connected to said wheel and to said cross-head, whereby said rock-shaft is rocked and said cross-head is reciprocated, by revolution of said wheel, substantially as described.

5. In a machine for the purpose described, a magazine 1 for outer sections, a magazine 2 for inner sections, the bottom of said magazine 1 having an opening and a shelf therein, a guide-bar secured to said magazines as shown, and having a longitudinal slit therein, a rock-shaft having a crank on one end thereof, a cross-head mounted slidably and non-rotatably on said rock-shaft, an inserter-blade connected pivotally to said cross-head and projecting into or through said slit in said guide-bar, a wheel, a pair of cam-lips 28, 29 on said wheel, an opening adjacent to

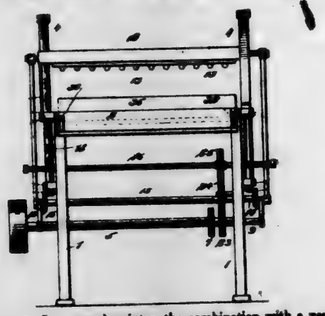
each of said lips and a pitman connected to said wheel and to said cross-head, whereby said rock-shaft is rocked and said cross-head is reciprocated, by revolution of said wheel, a shaft parallel to said rock-shaft, a crank-shaft, a crank-wheel on said shaft, a separator-finger connected at one end to a rocker-arm and between its ends to the face of said crank-wheel, said separator-finger being so adjusted as to enter between the folds of an outer section and depress the lower fold thereof through said opening in the bottom of the magazine, the end of the upper fold being supported by said shelf, and means for rotating said crank-wheel and said cam-wheel synchronously, substantially as described.

707,588. ATTACHMENT FOR HARNESS. NIKOLAUS HEBRAND, Coldspring, Minn., assignor of one-half to Frank Paul, Coldspring, Minn. Filed June 3, 1901. Serial No. 63,671. (No model.)



Claim.—A harness attachment consisting of a frame supported from the harness and provided with a detachable tug-connecting bolt, a hook loosely hung upon said frame, and an upwardly-extending step upon the lower side of the frame, said hook being formed with an elongated eye to allow it to be carried past said step, as and for the purpose set forth.

707,589. STARCH-PRINTER. DANIEL M. HOLMES, Arlington, N. J., assignor to Charles S. Fowler and Lucius A. Rockwell, New York, N. Y. Filed Jan. 2, 1902. Serial No. 88,104. (No model.)



Claim.—1. In a starch-printer, the combination with a vertically-movable platen, of means for imparting a horizontal, eccentric movement to the same.

2. In a starch-printer, the combination with a vertically-movable platen, of rotatable, eccentric guides therefor.

3. In a starch-printer, the combination with the bed and a starch-tray, of horizontally-movable bars bearing spring-actuated fingers arranged to pass beneath a tray and engage therewith, substantially as shown and described.

707,590. DOUBLE-STROKE DEPOSITOR. DANIEL M. HOLMES, Arlington, N. J., assignor to Charles S. Fowler and Lucius A. Rockwell, New York, N. Y. Filed Jan. 2, 1902. Serial No. 88,105. (No model.)

Claim.—1. The combination with a material hopper or holder provided with exit orifices or ports, of a discharging device in which is comprised two independently, partially-rotatable, oscillatory members located in a common throat, one of said members being provided with ports or orifices.

2. The combination with a material hopper or holder provided with exit orifices or ports and a division or partition, of discharging devices in each of which is comprised two independently, partially-rotatable, oscillatory members, located in a common throat one of said members having openings or ports therethrough.

3. In a depositor, a discharging device in which is comprised two independently, partially-rotatable members, located in a common throat, as set forth, one of said members being perforated and arranged to come in contact with a projection extending into the throat.

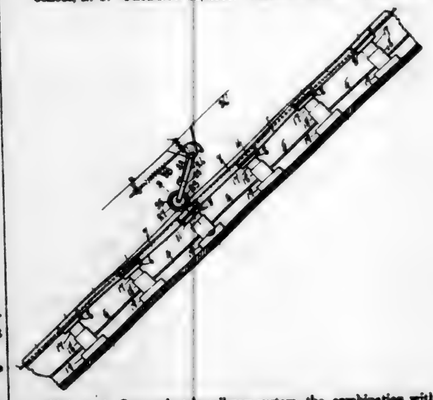
4. In a depositor, the combination with a discharging device in which is comprised two independently, partially-rotatable, oscillatory members, located in a common throat, of means for varying the oscillation of said members.

5. In a depositor, the combination with a material hopper or holder provided with exit orifices or ports and discharging devices at the bottom of the hopper, of directing devices in each of which is comprised a central exit-tube having communication with one side of the material-hopper, and a chamber surrounding said exit-tube having communication with the other side of the material-hopper, discharge-openings leading from said chamber, and means for rotating the bottom and inner wall of the chamber.

6. The combination with a fixed shell at the bottom of the material-hopper, of a central discharge-tube and a thimble rotatably held thereon; a supply-port at the top of the thimble and discharge-openings at the bottom of the thimble, and means for rotating the thimble.

7. The combination with a fixed shell at the bottom of the material-hopper, of a central discharge-tube and thimble rotatably held thereon, the thimble having a supply-port at the top and discharge-openings at the bottom, a pin located within the thimble, and means for rotating the thimble.

707,591. UNDERGROUND-TROLLEY SYSTEM. FRED A. HOWARTH, Johnstown, N. Y., assignor of one-half to Henry L. Shaver, Cohoes, N. Y. Filed Nov. 23, 1901. Serial No. 83,297. (No model.)



Claim.—1. In an electric-railway system, the combination with a supply-conductor; of a flexible tubular inclosure therefor comprising a series of insulated conductive sections; supports for said conductor extending through transverse apertures in the tubular inclosure wall, and means for yieldingly supporting said inclosure-sections out of contact with said conductor, substantially as described.

2. In an electric-railway system, the combination with a supply-conductor; of a flexible tubular inclosure therefor comprising a series of insulated conductive sections; supports for said conductor extending through transverse apertures in the tubular inclosure wall exteriorly of said inclosure; and springs for yieldingly supporting the inclosure-sections out of contact with said conductor and permitting said sections to be successively forced into contact therewith, substantially as described.

3. In an electric-railway system, a conduit of conductive material adapted to form a return-conductor; a supply-conductor contained therewithin and insulated therefrom; a flexible covering for said supply-conductor made up of sections of conductive material insulated from each other yieldingly supported out of contact with said supply-conductor and adapted to be successively forced into contact therewith while not in contact with the conductive portion of the conduit; in combination with a trolley or the like having parts of different polarity one adapted to contact with the conduit, and the other to contact with the sections of the flexible covering successively and depress them into contact with the supply-conductor.

4. In an electric-railway system, the combination with a plurality of stationary supports; of a plurality of supply-conductor sections detachably secured at their ends to the respective supports and connected thereby in a conductive series; a series of insulated tubular conductive inclosures for the intermediate portions of the respective supply-conductor sections; detachable tubular splice mechanism for connecting together the adjacent ends of the respective inclosure-sections, and a yielding support for the several splice mechanisms, substantially as described.

5. In an electric-railway system, the combination with a plurality of stationary supports, of a plurality of supply-conductor sections detachably secured at their ends to the respective supports and forming a conductive series; a series of insulated, conductive, tubular inclosures for the intermediate portions of the respective supply-conductor sections; sectional splice-boxes each inclosing a stationary supply-conductor and comprising a body provided with seats for the neighboring ends of neighboring supply-conductor inclosures; and a detachable cap adapted to clamp said ends in said seats; and yielding supports for said splice-boxes, substantially as described.

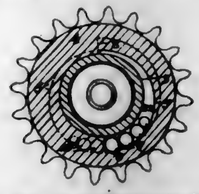
6. In an electric-railway system, the combination with a supply-conductor and fixed supports for the same; of a tube-section inclosing said conductor; a splice-box having separable clamping members; a splice-bushing projecting from the tube-section and inserted between the members of the splice-box; and an insulating-sleeve inclosing the inserted portion of the bushing and serving to insulate the tube-section from the splice-box, substantially as described.

707,592. ANTIFRICTION-COVER FOR BICYCLE-SADDLES. WILLIAM W. HUGHES, Urbana, Ohio. Filed Dec. 5, 1901. Serial No. 84,733. (No model.)

Claim.—1. An antifriction device for bicycle-saddles comprising a bifurcated cover firmly secured to the front and loosely secured to the rear ends of the saddle, substantially as described.

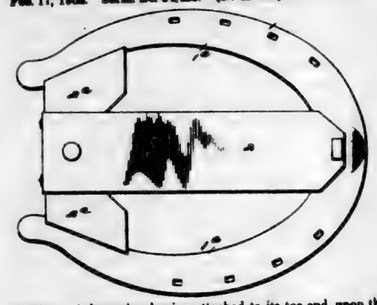
2. An antifriction device for bicycle-saddles comprising a cover slidingly secured to the saddle and having its rear portion bifurcated, substantially as described.

707,598. CLUTCH. FREDERICK W. JONES, London, England. Filed Aug. 13, 1900. Serial No. 26,731. (No model.)



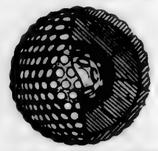
Claim.—In a clutch, the combination of a driving part, a driven part, a concentric surface of the driven part, a double eccentric surface on the driving part, a taper intermediate gripping-piece adapted to engage in one direction, a taper intermediate gripping-piece adapted to engage in the other direction, and a stop on the driving part dividing the double eccentric surface, the said stop being located between the larger ends of the two taper gripping-pieces, substantially as and for the purpose set forth.

707,594. HORSESHOE. CARL A. JUDSEN, Chicago, Ill. Filed Feb. 17, 1902. Serial No. 94,483. (No model.)



Claim.—A horseshoe having attached to its toe end, upon the inner upper edge a steel or metal guard-plate, having its rear end unattached to the shoe and provided with a transverse member, at said rear end, with its ends resting or bearing freely upon the shoe laterally, and a cushion of frictional or elastic material, said guard-plate and transverse member having downwardly-bent portions embracing or engaging said cushion and having passing therethrough fastenings securing in place said cushion, substantially as set forth.

707,595. MANUFACTURE OF PLAYING-BALLS. ELEAZER KEMPSHALL, Boston, Mass. Filed June 25, 1902. Serial No. 113,057. (No model.)



Claim.—1. A process in producing a playing-ball, consisting in inclosing a hard perforated sphere in a shell or layer of soft, resilient material, and compressing upon said layer a shell of hard plastic material, the compression being carried to an extent to force portions of said soft layer permanently into the perforations in said hard sphere.

2. A process in producing a playing-ball, consisting in providing a hard shell with perforations, enveloping said shell in soft rubber, and applying to said soft rubber under pressure plastic material which is rendered soft by heat, the pressure being carried to an extent to force portions of said soft rubber into said perforations, and being maintained while said plastic material hardens.

3. A process in producing a playing-ball, consisting in inclosing the perforated shell of hard material in an envelop of soft rubber, and welding upon said envelop by means of heat and compression a shell consisting of segments of plastic material, carrying the compression to an extent to force portions of said rubber into the perforations in said shell, and maintaining the compression until said shell hardens by cooling.

4. A process in producing a playing-ball, consisting in winding in miscellaneous directions upon a hard spherical center piece having openings, a strip of approximately pure sheet india-rubber, and then forming thereon under compression a shell of hard material, the compression carried to an extent to cause portions of said india-rubber to protrude into said openings.

5. A process in producing a playing-ball, consisting in winding under high tension in miscellaneous directions, upon a hard spherical hollow center piece having apertures, a continuous strip of thin approximately pure sheet india-rubber, and forming thereon a shell of plastic material by means of heat and compression, carrying the compression to an extent to cause portions of said india-rubber to protrude into said apertures, and maintaining the compression while the shell hardens.

6. A process in producing a playing-ball, consisting in inclosing a hard perforated sphere in a shell or layer of soft rubber, and compressing upon said layer a shell of gutta-percha, the compression being carried to an extent to force portions of said rubber layer permanently into the perforations in said hard sphere.

7. A process in producing a playing-ball, consisting in providing a hard shell with perforations, enveloping said shell in windings of soft rubber, and applying to said windings under pressure plastic material which is rendered soft by heat, the pressure being carried to an extent to force portions of said windings into said perforations, and being maintained while said plastic material hardens.

8. A process in producing a playing-ball, consisting in inclosing the perforated shell of hard material in tense windings of soft rubber, and welding upon said envelop by means of heat and compression a shell consisting of segments of gutta-percha, carrying the compression to an extent to force portions of said windings into the perforations in said shell, and maintaining the compression until said shell hardens by cooling.

9. A process in producing a playing-ball, consisting in winding in miscellaneous directions upon a hard spherical center piece having openings, approximately pure sheet india-rubber, and then forming thereon under pressure a shell of gutta-percha, the pressure being carried to an extent to cause portions of said india-rubber to protrude into said openings.

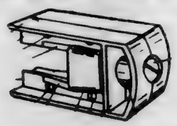
10. A process in producing a playing-ball, consisting in winding in miscellaneous directions, upon a hard spherical hollow center piece having apertures, a continuous strip of thin approximately pure sheet india-rubber under sufficient tension to cause the windings to adhere to one another, and forming thereon a shell of gutta-percha by means of heat and compression, carrying the compression to an extent to cause portions of said windings to protrude into said apertures, and maintaining the compression while the gutta-percha shell hardens.

11. A process in producing a playing-ball, consisting in inclosing a depressible shell of rubber windings between segments of plastic material, and applying heat and compression to said segments so as to reduce said rubber sphere in bulk and also cause said segments to weld.

12. A process in producing a playing-ball, consisting in inclosing a depressible shell of tense windings of soft rubber between segments of plastic material, applying heat and compression to said segments so as to cause them to soften and weld and also to cause said rubber sphere to become reduced in diameter, and maintaining the compression while the shell cools and hardens.

13. The process in producing a playing-ball, consisting in forming a depressible shell by winding approximately pure soft rubber, the latter being wound, under sufficient tension to cause the rubber to adhere layer to layer, surrounding said sphere by heated plastic material, subjecting the whole to compression to an extent to cause said sphere to be reduced in bulk, and maintaining the compression while the plastic material hardens.

707,596. FOUNDRY PATTERN-CLAMP. ERNST J. KIRK, Fort Wayne, Ind. Filed July 18, 1901. Serial No. 68,763. (No model.)



Claim.—1. A foundry pattern-clamp consisting of a pair of centrally-slotted plates, having inclined ways upon their outer faces adjacent to said slot as shown; a clamp or key provided upon its opposite ends with a pair of inclined faces, arranged in said slot and adapted for a binding engagement with the said inclined ways; and the means described for securing said plates in such engagement.

2. In a pattern-clamping device a pair of plates having a longitudinal recess therein, and inclined ways adjacent to said recess; a clamp slidably mounted in said recess and having upon each end thereof a pair of inclined faces adapted to engage the said inclined ways as shown; and means for forcing the said clamp upward on said ways and for securing the same in such position for the purpose specified.

3. A pattern-clamp consisting of a pair of plates provided with inclined ways; an interlocking clamp mounted on said ways and provided with faces adapted to engage said ways; and means for forcing said wedge upward on said ways.

4. In a pattern-clamp the combination of a pair of plates rigidly secured to the pattern-sections, each of which plates is provided upon its outer face with a pair of inclined ways; a clamp having upon two opposite sides thereof a pair of oppositely-arranged inclined faces adapted to engage said ways; and a screw mounted within said plates and adapted to force the said wedge into a holding engagement with the said ways.

707,597. AMALGAMATOR. ERNST J. KIRK, Fort Wayne, Ind. Filed Aug. 12, 1901. Serial No. 71,723. (No model.)

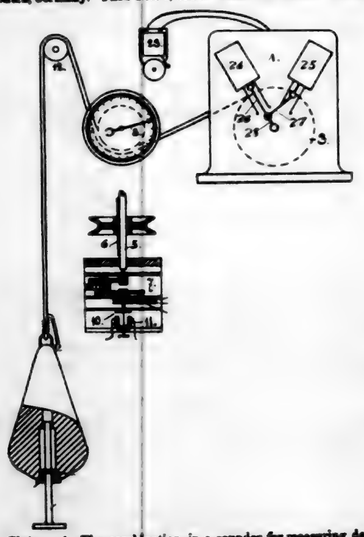
Claim.—1. In an amalgamator, a rotary open-topped cylindrical tank; a tilting adjustable support for the said tank; a revolvable spiral agitator mounted in said tank in vertical arrangement and adapted to impart a positive downfeed to the contents thereof; means for draining said tank while in operation; and means for actuating said tank.

2. An inclined rotary tank having a concave bottom and a peripheral overflow-trough; a tilting adjustable support for said tank; an upright spiral agitator revolubly mounted in said tank and adapted to impart a positive downfeed; means for centrally draining said tank while in operation consisting of an inner and an outer sleeve, the inner sleeve having a lateral outlet-opening, and being adapted to be fixed to said tank, the outer sleeve having a vertical adjustment on the inner sleeve and adapted to close said lateral opening; and means for operating the said outer sleeve.

707,598. COMB. WOLF KRONHEIM, Hanover, Germany. Filed Dec. 28, 1901. Serial No. 87,320. (No model.)

Claim.—A comb with straight teeth having the back on one side of the straight teeth, so that the spaces between the latter reach from the points of the teeth along one side of the back to the rear side of the comb, substantially as set forth.

707,599. LEAD FOR MEASURING DEPTHS. ERNST KRUHSOW, Soutra, Germany. Filed Feb. 7, 1902. Serial No. 93,054. (No model.)

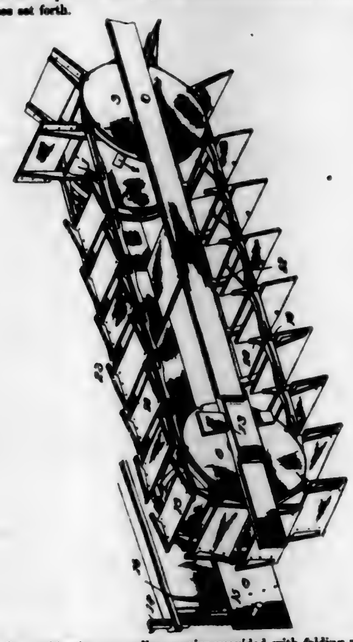


Claim.—1. The combination, in a sounder for measuring depths, of a lead weight having a hole lengthwise and inside contacts, with a movable piston provided with a plate-like end, the said lead weight secured to a rope having electric wires, an electrical ringing apparatus and an electromagnet, in connection with said wires, a counter operated by the aforesaid electromagnet, all as shown and described.

2. The combination, in a sounder for deep-sea measuring, of a lead weight having a movable piston and inside contacts, with a counter for the length of rope run out, having an electromagnet and an armature consisting of an iron plate attached to a hand having a claw grasping over the hand of the counter all as and for the purpose set forth.

707,600. REDLESS PROPELLER. ADAM KUHVE, Colby, Wis. Filed Dec. 21, 1901. Serial No. 86,801. (No model.)

Claim.—1. An endless carrier provided with folding paddles having extensions and a guard arranged parallel with and immediately below the upper portion of the said carrier for the aforementioned extensions of the paddles to travel upon to hold the paddles folded, substantially as and for the purpose set forth.



2. In combination, an endless carrier provided with folding paddles having extensions, rotary supports for opposite ends of the said carrier, means for adjusting one of the supports vertically to change the horizontal inclination of the carrier, and a guard located parallel with and immediately below the upper portion of the carrier for the aforesaid extensions of the paddles to travel upon to hold said paddles folded, said guard being attached to and movable with the aforesaid rotary support to preserve a fixed position with reference to the carrier, substantially as set forth.

3. In combination, an endless carrier comprising companion chains and cross-bars tying the chains and pivotally connecting the links thereof, paddles, cleats secured to the end portions of the paddles and having their inner ends extended and transversely apertured to receive the cross-bars upon which the paddles are mounted to swing, said cleats having their rear end portions cut away to admit of the paddles folding close, substantially as set forth.

4. In combination, an endless carrier, folding paddles applied to said carrier, and arms secured to the end portions of the paddles and adapted to bear against links of the carrier-chains and to hold the paddles in an approximately vertical position, substantially as set forth.

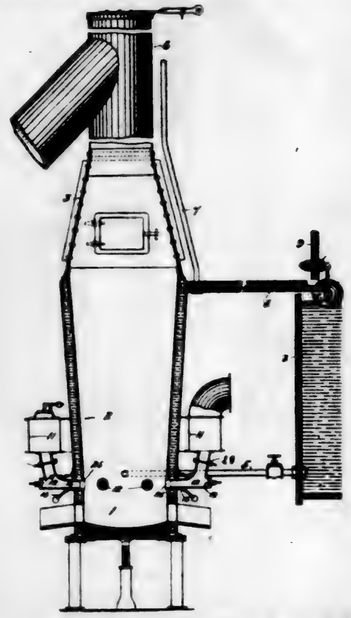
5. In combination, an endless carrier provided with paddles or blades, rotary supports for the end portions of the said carrier, mountings for one of the rotary supports having right-angularly-disposed intersecting openings, bearing-blocks for the last-mentioned rotary support having open slots in one end, and keys coöperating with the slots of the bearing-blocks and with the vertical openings of the said mountings to hold the bearing-blocks in place and admit of adjustment thereof, substantially as set forth.

6. In combination, an endless carrier provided with paddles, rotary supports for the end portions of said carrier, a pivoted frame for one of the said rotary supports, an interlocking rib and groove formed on the arc of a circle concentric with the pivotal center of said frame, and means for adjusting the said pivoted frame consisting of a set-screw and coöperating nut, each having a swivel-mounting, substantially as specified.

707,601. SMELTING-FURNACE. CHARLES LAUDELIN, St. Louis, Mo. Filed Apr. 11, 1901. Serial No. 55,331. (No model.)

Claim.—1. A smelting-furnace having double walls, and a tube extending through said walls for the tuyer-opening, said tube being beaded on each side of the wall-plates, substantially as described.

2. A smelting-furnace comprising a tuyer-pipe having a hole in the bottom thereof, and a lever pivotally mounted on the under side of said pipe alongside of said hole, said lever having on one arm a plate provided with a hole adapted to register with said first-mentioned hole and having its other arm weighted, whereby said lever acts automatically to clamp a sheet of paper between the tuyer-pipe and said plate and over the holes therein, substantially as described.



3. A smelting-furnace comprising a tuyer-pipe, an end plate therefor having an inspection-hole therein, said end plate having downwardly-converging lugs, and a wedge-shaped plate fitting in said lugs and having a hole adapted to register with the inspection-hole, and said plate being arranged to clamp a sheet of mica over the inspection-hole, substantially as described.

707,602. SMELTING-FURNACE. CHARLES LAUDELIN, St. Louis, Mo. Filed Dec. 23, 1901. Serial No. 87,576. (No model.)

Claim.—1. The combination with a smelting-furnace having hollow walls constituting a water-jacket, of a water-tank on a level therewith, a pipe connecting the lower portion of said water-tank with the lower portion of said water-jacket, and a pipe connecting the upper portion of said water-jacket with the upper portion of said water-tank, substantially as described.

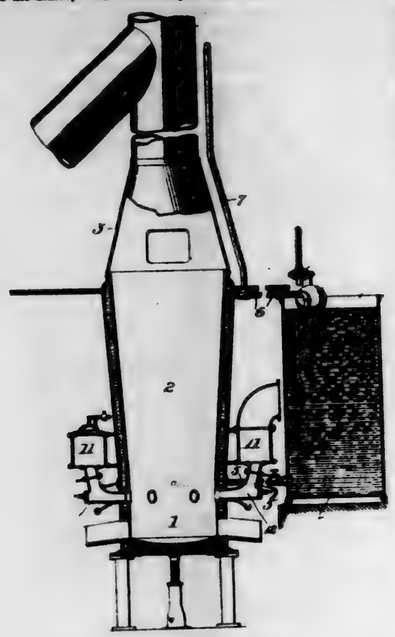
2. The combination with a smelting-furnace having hollow walls constituting a water-jacket, of a water-tank, a pipe connecting the lower portion of said water-tank with the lower portion of said water-jacket, and a pipe connecting the upper portion of said water-jacket with the upper portion of said water-tank, and means for maintaining the level of water in said tank below the upper portion of said pipe, substantially as described.

3. The combination with a smelting-furnace having hollow walls constituting a water-jacket, of a water-tank, a pipe connecting the lower portion of said water-tank with the lower portion of said water-jacket, and a pipe connecting the upper portion of said water-jacket with the upper portion of said water-tank, and automatically-acting means for maintaining the level of water in said tank nearly even with the upper portion of said pipe, substantially as described.

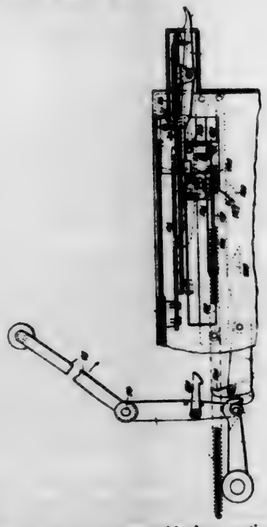
4. The combination with a smelting-furnace having hollow walls constituting a water-jacket, of a water-tank, a pipe connecting the lower portion of said water-tank with the lower portion of said water-jacket above the bottom of said jacket, and a pipe connecting the upper portion of said water-tank with the upper portion of the water-jacket, substantially as described.

5. The combination with a smelting-furnace having hollow walls constituting a water-jacket, of a water-tank, a pipe connecting the lower portion of said water-tank with the lower portion of said water-jacket, and a pipe connecting the upper portion of said water-tank with the up-

per portion of the water-jacket, said upper pipe having a vertical branch open to the atmosphere, substantially as described.



707,608. LOCKING DEVICE FOR THE OPERATING-CRANKS OF CASH-REGISTERS. CARL LAUBICH, Berlin, Germany. Filed June 5, 1900. Serial No. 19,094. (No model.)



Claim.—1. The combination with the operating-crank of a cash-register, of a locking device for holding the same against movement, a slide for releasing said locking device, a spring tending to retract said slide, means for holding the slide normally advanced, and check-controlled means for releasing said holding means, substantially as described.

2. The combination with the operating-crank of a cash-register, of a locking device for holding the same against movement, a slide adapted to release said locking device on its rearward movement, a spring for drawing said slide backward, a catch-lever for holding said slide advanced against the tension of the spring and check-controlled means for holding said catch-lever normally locked, substantially as described.

3. The combination with the operating-crank of a cash-register, of a locking device for holding the same against movement, a slide adapted to release said locking device on its rearward movement, a spring for drawing said slide backward, a catch-lever for holding said slide advanced against the tension of the spring, a locking-finger engaging said catch-lever to hold it normally against movement a check-receiving space in said slide, and a finger projecting into the path of the check and operatively connected with said locking-finger, substantially as described.

4. The combination with the operating-crank of a cash-register, of a locking device therefor, a slide adapted to release said locking device, a spring tending to retract said slide, a catch-lever pivoted to the slide and engaging a rigid portion of the casing to hold the slide against movement, the rear end of said catch-lever projecting through an opening in the slide, a rock-shaft above the slide having a locking-finger engaging the rear end of said lever, said slide having a check-receiving space or guide, and a finger carried by said rock-shaft and projecting into the path of the check, substantially as described.

5. In combination with the operating-crank of a cash-register, of a locking device therefor, a slide adapted to release said locking device on its backward movement, a spring for retracting said slide, a catch-lever pivoted to the slide and adapted to project through an opening in the casing and automatically engage the edge thereof at the limit of its forward movement to prevent backward movement of the slide, the rear end of said lever projecting into an opening in the slide, a rock-shaft having a locking-arm engaging said rear end, said slide having a check-receiving space or guide, an arm or finger on the shaft projecting into the path of the check, and a hook for engaging the check when the slide is retracted whereby said check is removed from the slide on the forward movement of the latter, substantially as described.

6. The combination with the operating-crank of a cash-register, of a pivoted hook for holding said arm against movement, an oscillating lever adapted to disengage said hook, a slide adapted to oscillate said lever on the backward movement of the slide, a spring tending to retract said slide, a catch-lever normally locked against movement for holding said slide advanced against the tension of the spring, and check-controlling means for unlocking said lever, substantially as described.

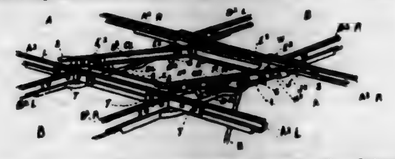
7. The combination with the operating crank-shaft of a cash-register, of an arm carried by said shaft, having a pin, a pivoted hook engaging said pin, an oscillating lever, a pawl on the rear end thereof engaging said hook, check-controlled slide adapted to operate said oscillating lever to disengage the hook from the pin, and a hook-shaped pawl on the arm adapted, on one rotation of the arm to disengage the pawl from the hook, substantially as described.

8. The combination with the operating-crank of a cash-register, of a device for locking the same against movement, an oscillating lever adapted to release said locking device, a slide having a check-receiving space or guide, means released by the insertion of a check for holding said slide normally locked, a supplemental slide having a projection for operating said oscillating lever, a retracting-spring connected to said supplemental slide, a projection on the supplemental slide adapted to engage a projection on the check-carrying slide to move said check-carrying slide rearwardly, a pawl carried by the supplemental slide adapted to engage the rear face of the projection whereby forward movement of the supplemental slide secures forward movement of the main slide, and means whereby said pawl is released at a determined point to permit the supplemental slide to move forward without affecting the main slide, substantially as described.

9. The combination with the operating-crank of a cash-register, of a device for locking the same against movement, an oscillating lever adapted to release said locking device, a slide having a check-receiving space or guide, means released by the insertion of a check for holding said slide normally locked, a supplemental slide having a projection for operating said oscillating lever, a retracting-spring connected to said supplemental slide, a projection on the supplemental slide adapted to engage a projection on the check-carrying slide to move said check-carrying slide rearwardly, a pawl carried by the supplemental slide adapted to engage the rear face of the projection whereby forward movement of the supplemental slide secures forward movement of the main slide, said pawl having a straight lower edge, a guide against which the said straight lower edge bears during the rear portion of the movement of said slide, said guide having a cut-away portion to permit rocking of the pawl to disengage it from the projection on the main slide, substantially as described.

707,604. RAILROAD-CROSSING AND SWITCH FOR SAME. CHARLES LEIBENGOOD, Lawrenceburg, Ind. Filed Apr. 13, 1901. Serial No. 55,444. (No model.)

Claim.—1. In a construction where tracks cross, track B having rails substantially continuous, track A whose sections of rails between the rails A are pivotally connected to each other by parallel rods, and are adapted to turn together as a unit, and a bolt having a bolt H, a sleeve or holder J^3 therefor, a spring for advancing the bolt, the stationary mechanism the inner side of the stationary rail provided with the recess for engaging the bolt, means for operating the rail-sections located between the stationary rails, and adapted to withdraw the bolt as the rail-sections are opened away from track B, substantially as and for the purposes specified.



2. In a construction where tracks cross, the rail-sections between track A adapted to turn simultaneously, and provided with a locking-bolt adapted to engage a recess of the fixed mechanism, and a pivoted lever having arms adapted to alternately impinge against the mechanism of the rail-sections, each arm provided with an adjusting device for increasing or shortening its play relative to such fixed mechanism, and a connection between their lever and the locking-bolt whereby a movement of the lever unlocks the bolt, and a continued movement of the lever operates the rail-sections, substantially as and for the purposes specified.

3. In the construction of two tracks crossing one another, the combination of the continuous rails of one and the movable rail-sections of the other, these rail-sections located between the rails of the other track, the rail-sections pivoted as D^2 to their respective beds, connecting-rods E, pivoted to the rail sections, bearings O on which the sections rest, the connecting-rods each pivoted to one side of one rail-section and to the opposite or farther side of the other section, but one rod being pivoted on the inner side of one rail-section while the other rod is pivoted on the outer side of that section, means for opening and closing the rail-sections, and means for locking and unlocking these sections, substantially as and for the purposes specified.

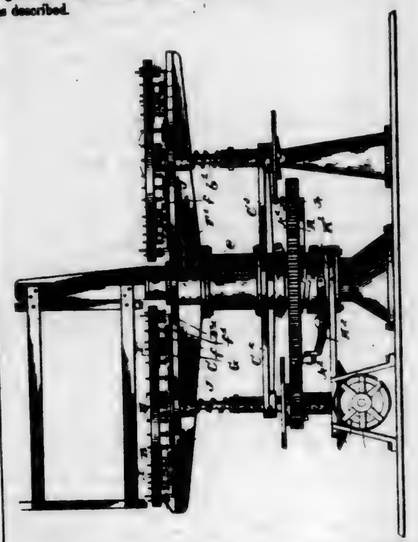
4. In the construction of two tracks crossing one another, the combination of the continuous rails of one and the movable rail-sections of the other, these rail-sections located between the rails of the other track, the rail-sections pivoted at D^2 to their respective beds, connecting-rods E, pivoted to the rail-sections, bearings O on which the sections rest, the connecting-rods each pivoted to one side of one rail-section and to the opposite or farther side of the other section, but one rod being pivoted on the inner side of one rail-section while the other rod is pivoted on the outer side of that section, and lever M pivoted at M^2 to the rail, and having arms M^3 and M^4, each provided with an adjusting-screw M^5, a bolt H, sliding in sleeve and adapted to engage recess W, of the fixed mechanism, a spring K, for advancing the bolt, a connection H^2 between the bolt H and the sleeve J^3, substantially as and for the purposes specified.

5. In the construction of two tracks, crossing one another, the combination of the continuous rails of one track and the movable rail-sections of the other, these rail-sections located between the rails of the other track, and pivoted to their respective beds, connecting-rods pivoted to the rail-sections, a bolt H sliding in sleeve J^3 and adapted to engage the recess W located on the inside of the rail A^2, a spring for advancing the bolt, the sleeve J^3 being provided with the extension J^5 for connecting it to the rail, and means for withdrawing the bolt and moving the sections opening and closing the rail-sections, substantially as and for the purposes specified.

707,605. MACHINE FOR MAKING BASKET-WEBS. PHILLIP F. LUBY, St. Joseph, Mich. Filed Oct. 16, 1901. Serial No. 78,229. (No model.)

Claim.—1. In a machine for use in making baskets, the combination of a hopper or holder in which strips of material are held flatwise one upon another, and a rotary member carrying automatically-actuated pins or fingers adapted and arranged for engaging and successively releasing said strips of material and distributing or arranging the same in suitable web form upon the top of said rotary member, substantially as described.

2. In a machine for making basket-webs, the combination of means for properly holding the strips of material, rotary means for distributing and arranging the strips of material in suitable web form, said distributing means comprising a plurality of automatically-actuated pins or fingers adapted and arranged to engage and successively release the said strips of material, the relative movement between the said pins or fingers and the means for supporting the strips of material causing each released strip of material to stand at an angle with reference to the remaining or unreleased strips, and means for causing the desired rotary movement on the part of said distributing means, the axis of such rotary movement extending transversely through the center of the strips of material, substantially as described.



3. An automatic machine for distributing and arranging suitable strips of material in suitable web form, comprising a holder adapted to hold the strips of material in a superimposed condition, or one on top of the other, a plurality of automatically-actuated pins or fingers adapted and arranged in position to engage and successively arrange or position the said strips of material, and pivotal connections whereby to permit relative rotary movement between the said holder and the said pins or fingers, said rotary movement being about an axis extending transversely through the stock of superimposed slats or strips of material, said strips of material when released from the holder being arranged crosswise to provide a basket-web of substantially disk form, substantially as described.

4. In a machine for making basket-webs, the combination of a holder for holding the strips of material, a rotary table adapted to receive the said strips of material, pins or fingers mounted upon said rotary table, and a cam for automatically engaging and operating said pins or fingers, so as to automatically remove the strips of material from the bottom of said holder, substantially as described.

5. In a machine for making basket-webs, the combination of a holder for holding the strips of material, a rotary table adapted to receive the said strips of material, pins or fingers projecting upwardly from said table, means for actuating said pins, said actuating means being adapted to cause two of said pins or fingers to rise at a time, so as to engage and remove the lowermost strip of material from the said holder, and suitable gearing for rotating said table, substantially as described.

6. In a machine for making basket-webs, the combination of a suitable hopper or holder for holding the strips of material, a rotary table adapted and arranged to rotate about a vertical axis below said hopper or holder, upwardly-projecting pins or fingers suitably mounted for vertical reciprocation in the rim or peripheral portion of said table, springs for keeping said pins normally depressed, cams for automatically raising said pins, said cams being adapted and arranged to raise two of said pins at a time, the upper ends of the pins thus actuated or raised engaging the lowermost strip of material in said hopper or holder, gearing for rotating said table, and a clutch for automatically disconnecting the driving power from said table, substantially as described.

7. A machine for making basket-webs comprising a plurality of rotary tables, suitable means for holding the strips of material in a superimposed condition, means for rotating one table at a time, each table being provided with upwardly-projecting pins or fingers, said pins being adapted to engage the lowermost strip of material, a carrier for intermittingly and successively bringing said tables into position to receive a suitable number of said strips of material, suitable cams or actuating devices for actuating said pins or fingers, the rotation of either table causing the pins or fingers of such table to rise two at a time, so as to release the lowermost strip of material and deposit the same upon the surface of the rotating table, suitable means for rotating said table and also said ta-

blo-carrier, and suitable clutch devices for automatically connecting and disconnecting the power to and from said table and table-carrier, substantially as described.

8. A machine for making basket-webs, comprising a suitable hopper or holder for holding the strips of material, a pair of rotary tables mounted for rotation upon a rotary table-carrier, upwardly-projecting pins or fingers carried by each rotary table, cams or actuating devices adapted to engage the lower ends of said pins, the upper ends of said pins being adapted to engage the lowermost strip of material in said hopper or holder, stems or spindles on said tables, clutch members carried by said stems or spindles, a power device provided with a constantly-rotating clutch member, the clutch member carried by the table stems or spindles being adapted to alternately engage the said lower clutch member which is constantly rotating, suitable gearing between said power device and said table-carrier, a suitable clutch device between said gearing and said table-carrier, and means for automatically operating said clutch, so as to automatically disconnect the power from the rotating table and at the same time automatically connect the power with the rotary table-carrier, so as to stop the rotation of the table and start the rotation of the table-carrier, the two tables thereby being interchanged, substantially as described.

9. In a machine for making basket-webs, the combination of means for suitably holding the strips of material, a rotary table adapted to receive the said strips of material, upwardly-projecting pins or fingers carried by said table, suitable cams for engaging the lower ends of said pins, said cams being shiftable toward and away from the center of said table, so as to prevent the said pins from being engaged in direct succession, substantially as described.

10. In a machine for making basket-webs, the combination of suitable means for holding the strips of material, a rotary table adapted to receive said strips of material, suitable pins or fingers projecting upwardly from said table, said pins or fingers being arranged in a plurality of sets or series, cams for engaging the lower ends of said pins or fingers, said cams causing the fingers to move upwardly and engage the lowermost strips of material, rotary cams shifting said cams which actuate the said pins or fingers, such shifting or moving of the finger-actuating cams causing the latter to engage and operate said sets or series of fingers in succession, and means whereby the rotation of said table will cause the said rotary cams to turn or rotate to the desired extent, substantially as described.

11. In a machine for making basket-webs, the combination of a suitable holder or hopper for holding the strips of material, a rotary table adapted to receive said strips of material, suitable pins or fingers projecting upwardly from said table, said pins or fingers being arranged in a plurality of sets or series and having their upper ends adapted to engage the lowermost strips of material, actuating devices for forcing said pins upward, rotary cams for shifting said actuating devices in a direction toward and away from the center of said table, so as to cause the different sets or series of fingers to be operated in succession, finger-wheels rigid with said rotary cams, and projections on said table adapted to engage the fingers of said finger-wheels, so as to rotate said cams, substantially as and for the purpose set forth.

12. In a machine for making baskets, the combination of a holder and of a plurality of pins or fingers, the said holder and the said pins or fingers being constructed and arranged for relative movement, so as to cause the strips of material to be deposited or arranged in the desired manner, and the said pins or fingers being arranged in a plurality of sets or series, and means for operating the sets in succession, substantially as described.

13. In a machine for making basket-webs, the combination of suitable means for holding strips of material, rotary means for causing the said strips of material to arrange themselves in suitable web form, and a plurality of pins or fingers adapted and arranged to engage and determine the relative positions of the said strips of material, said pins or fingers being arranged in a plurality of sets or series, and means for operating the different sets or series successively, substantially as described.

14. In a machine for making basket-webs, the combination of a holder for holding the strips of a material in a superimposed condition, a plurality of suitably-actuated pins or fingers for engaging and determining the relative positions of the strips of material, said pins or fingers being arranged in a plurality of sets or series, and a rotary member for causing relative movement between the said holder and the said pins or fingers, so as to cause the said strips of material to arrange themselves in suitable web form, the said rotary means being adapted to rotate a number of times for the purpose of operating the different sets or series of fingers in succession, thereby effecting the desired arrangement of the strips of material forming the web, substantially as described.

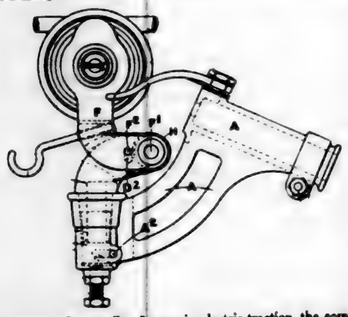
15. In a machine for making basket-webs, a rotary table adapted and arranged to receive and hold the strips of material and provided with means for determining the relative positions of said strips, and a hopper arranged above said table and adapted to hold a stack or bundle of strips, the strips then held in the hopper being successively released therefrom by the said means for determining the relative positions of the strips, substantially as described.

16. In a machine for making basket-webs, the combination of a holder for suitably holding the strips of material, rotary means for causing the strips of material to arrange themselves in suitable web form, and a series of devices for placing the strips and determining the proper relative positions of the latter, said rotary means being adapted and arranged for a plurality of rotations in effecting the desired arrangement or disposition of the strips of material forming the web, substantially as described.

17. A machine for forming webs for baskets, consisting of a frame, means for supporting a stack of staves and for imparting a relative circular motion around the transverse center of the stack to one or more staves in such stack, and means for automatically successively restraining one or more staves in such stack in successive series.

18. In a machine for making basket-webs in which the slats or strips of material are arranged crosswise to the form of a web or disk, the combination of a member adapted to hold the slats or strips of material in a superimposed or one-on-top-of-the-other condition, the slats or strips of material in this condition being parallel and in the form of a stack, automatically-actuated devices adapted to engage said slats or strips of material and successively release them from the position in which they are held by the said member, and pivotal connections whereby to permit of a relative rotary movement between said member and said automatically-actuated devices for engaging the slats or strips of material, such rotary movement being about an axis extending transversely through the stack or bundle of slats or strips of material.

707,606. TROLLEY FOR USE IN ELECTRIC TRACTION. JOHN G. LAYCOCK, Sheffield, England. Filed Dec. 14, 1901. Serial No. 85,896. (No model.)



Claim.—1. In a trolley for use in electric traction, the combination of a socket, a spindle therein, a lever pivoted to said spindle, a spring acting between the spindle and the lever and a trolley-wheel mounted on the lever, for the purpose set forth.

2. In a trolley for use in electric traction the combination of a socket, a spindle therein bent above the socket, a bent lever pivoted to the spindle, a spring acting between the spindle and lever and a trolley-wheel mounted on the lever for the purpose set forth.

3. In a trolley for use in electric traction the combination of a socket, a spindle therein, a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever and a hook on the lever for operating the boom for the purpose set forth.

4. In a trolley for use in electric traction the combination of a socket, a spindle therein, a lever pivoted to the spindle, a spring acting between the lever and spindle, a trolley-wheel mounted on the lever, and a fork mounted adjacent to and embracing the trolley-wheel for the purpose set forth.

5. In a trolley for use in electric traction the combination of a socket, a spindle therein, a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever, a hook on the lever for operating the boom, and a fork mounted adjacent to and embracing the trolley-wheel for the purpose set forth.

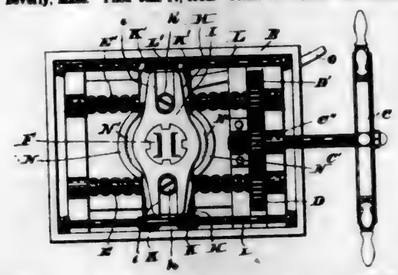
6. In a trolley for use in electric traction the combination of a socket, a spindle therein, a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever, a circumferential groove extending partially around the spindle and a pin engaging the groove by passing through a hole in the socket for the purposes set forth.

7. In a trolley for use in electric traction the combination of a conical socket, a conical spindle therein a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever and an adjustable pivot-point at the bottom of the socket for the purpose set forth.

8. In a trolley for use in electric traction the combination of a conical socket, a conical spindle therein a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever, a circumferential groove extending partially around the spindle, a pin passing through the socket and engaging the groove and an adjustable pivot-point at the bottom of the socket for the purpose set forth.

9. In a trolley for use in electric traction the combination of a conical socket, a conical spindle therein, a lever pivoted to the spindle, a spring acting between the spindle and lever, a trolley-wheel mounted on the lever, a hook on the lever for operating the boom, a fork mounted adjacent to and embracing the trolley-wheel, a circumferential groove extending partially around the spindle, a pin passing through the socket and engaging the groove and an adjustable pivot-point at the bottom of the socket for the purpose set forth.

707,607. SHIP'S STEERING APPARATUS. MAURICE B. LOWELL, Beverly, Mass. Filed Jan. 17, 1902. Serial No. 90,206. (No model.)



Claim.—1. In a ship's steering apparatus, a rudder-post having secured to it a toothed ring M, in combination with pivoted levers N, N, having toothed inner surfaces adapted to be interlocked with said toothed ring, a pivoted brake-lever O, connected to the levers N, N, as described and means for adjusting and securing said brake-lever in position substantially as and for the purpose set forth.

2. In a ship's steering apparatus, a rudder-post, a wheel-box inclosing the same and a removable cover combined with a rudder-indicator journaled in said cover and detachably connected to the rudder-post substantially as and for the purpose set forth.

707,608. STAIR-PAD. MARTIN H. MARCUS, New York, N. Y. Filed Dec. 13, 1901. Serial No. 85,750. (No model.)

Claim.—1. A stair-pad comprising two connected layers of cloth or other flexible sheet material forming a pocket, stuffing within said pocket, quilting which extends through the stuffing and said two layers, and a stiffener arranged exteriorly of said pocket and covering the quilting on the outer face of one of said layers.

2. A stair-pad comprising three layers of cloth or other flexible sheet material connected at one end and located in superposed, substantially parallel planes, and forming two separate pockets between them, stuffing in one of said pockets, quilting which extends only through said stuffing and through the two layers which inclose it between them, but not through the other pocket, and a stiffener located in said other pocket so as to cover the quilting on the middle layer.

3. A stair-pad comprising three superposed layers of cloth or other flexible sheet material connected at one end and forming two separate pockets, stuffing in one of said pockets, a stiffener in the other pocket, additional stuffing between the stiffener and the central layer, and quilting which extends through the stuffing in the first-named pocket and terminates at the central layer so as to be covered by the stuffing in the pocket which contains the stiffener.

4. A pad comprising two connected pieces of cloth or other flexible sheet fabric one of which is about twice as wide as the other, the wide piece being doubled to form two layers, one of which has a projecting flap, stuffing between the narrow piece and the flap layer of the wide piece, and a stiffener between the narrow piece and the other layer of the wide piece, the flap of the wide piece extending over the end of the stiffener and over the free ends of the two flexible pieces.

5. A pad comprising three layers of cloth or other flexible sheet material, one of said layers having a projecting flap at its free edge, stuffing between the upper and middle layers, and a stiffener between the lower and middle layers, the said flap being bent around and over the end of the stiffener and the adjacent portions of the other layers.

6. A pad comprising three layers of cloth or other flexible sheet material, one of said layers having a projecting flap at its free edge, quilted stuffing between the upper and middle layers, and a stiffener located between the lower and middle layers, and bent at one end to form a nose for the pad, the said flap being bent around and under the nose of the pad.

7. A pad comprising three layers of flexible sheet material connected to form two pockets and having their raw edges at the seams located within the pad so that they will not be exposed to view, quilted stuffing in one of said pockets and a stiffener in the other pocket.

8. A pad comprising three layers of flexible sheet material stitched together along their sides and having their raw edges arranged interiorly of the pad, said three layers forming two pockets, stuffing located in one of said pockets and a stiffener located in the other pocket and bent at one of its ends to form a nosing for the pad.

707,609. DEVICE FOR HOLDING SPRING-ACTUATED CURTAINS. JOSEPH H. MILAM, Washington, D. C., assignor to Curtain Supply Company, Jersey City, N. J., and Chicago, Ill., a Corporation of New Jersey. Filed May 25, 1901. Serial No. 61,897. (No model.)

Claim.—1. A head for shade-holding fixtures of the character described provided with a friction-surface comprising an endless band arranged to have a portion projecting beyond the head, and means on the head for carrying the band; substantially as described.

2. In a curtain-holding device, the combination with a shade-stick and a fixed guide, of a friction-head carried by the stick having rollers in its opposite ends, an endless band extending around the rollers and projecting beyond the guide, and means for creating a frictional engagement between the stationary guide and the endless band; substantially as described.

3. In a curtain-holding device, the combination with a shade-stick and a fixed guide, of a friction-head carried by the stick having rollers at its opposite ends, an endless band extending around the rollers and projecting beyond the guide, means for creating a frictional engagement between the stationary guide and the endless band, and an intermediate support for the band; substantially as described.

4. A head for shade-holding fixtures provided with separated guides, and a revolubie friction-band adapted to work around said guides and projecting outwardly slightly beyond the plane of the end of the head; substantially as described.

5. A shade-holding fixture comprising a stick adapted to be attached to the shade, heads at the opposite ends of the stick, a friction-band carried by each head, and adjusting means for imparting the desired holding-pressure to the bands; substantially as described.

6. A shade-holding fixture comprising a stick adapted to be attached to the shade, oppositely-disposed heads at the ends of the stick, separated guides in each head, and a band carried by each head and adapted to move longitudinally thereof around said guides; substantially as described.

7. A shade-holding fixture comprising a stick adapted to be attached to the shade, oppositely-disposed heads at the ends of the stick, separated guides in each head, a band carried by each head and adapted to move longitudinally thereof around said guides, and adjusting means for imparting the desired holding-pressure to the bands; substantially as described.

8. A shade-holding fixture comprising a stick adapted to be attached to the shade, oppositely-disposed heads at the ends of the stick, guide-rollers at the ends of each head, a friction-band carried by each head and

adapted to move longitudinally thereof around said rollers, and means for imparting to said bands the desired holding-pressure; substantially as described.

9. In combination with a stick adapted to be attached to a shade, holding means including a head carried by the stick and provided with separated guides, and a friction-band adapted to work over said guides substantially as described.

10. In combination with a stick adapted to be attached to a shade, holding means including a head carried by the stick and provided with separated guides, and a revolable flat friction-band adapted to work over said guides; substantially as described.

11. In combination with a stick adapted to be attached to a shade, holding means including a head carried by the stick and provided with a flat movable friction-band, and guiding means for said band; substantially as described.

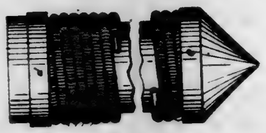
12. In combination with a stick adapted to be attached to a shade, holding means including a head carried by the stick and provided with a friction-band movable independently of the head; substantially as described.

13. In combination with a stick adapted to be attached to a shade, holding means including a head carried by the stick and provided with a friction device adapted to travel along the face of the head when the stick is moved up or down; substantially as described.

707,610. CARRYING DEVICE. JULIUS MOELLER, Moscow, Russia. Filed Aug. 23, 1901. Serial No. 72,861. (No model.)

Claim.—In combination, a belt, shoulder-straps crossing at the back and secured to the back of said belt at their rear ends, adjustable connections between the front ends of said straps and the front portion of said belt, an adjustable connection for the ends of said belt and loops connected to said belt and comprising a pair of straps A secured one to each side of the belt where it rests on the hips and a second pair of straps *i* secured to the belt near the adjoining ends, said straps A and *i* having means for detachably connecting their free ends, substantially as described.

707,611. SAND-SCREEN FOR WELL-TUBES. CLEOPHAS MONJEAU, Middletown, Ohio. Filed Feb. 25, 1902. Serial No. 95,549. (No model.)



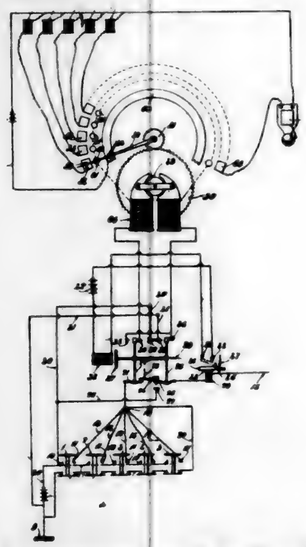
Claim.—1. A "tube-point" sand-screen for tube-wells, consisting of a perforated cylindrical core having spirally wound thereon a hollow strip of any suitable cross-section, leaving a substantially continuous spiral opening between contiguous edges, said strip being provided with external channels communicating with said spiral opening, and a binding element extending through the spiral opening and holding the coil, substantially as set forth.

2. A "tube-point" sand-screen for tube-wells consisting of a perforated cylindrical core having spirally wound thereon a continuous tubular coil of wire, and a binding-wire extending longitudinally through the coil, substantially as set forth.

3. A "tube-point" sand-screen for tube-wells consisting of a perforated cylindrical core having spirally wound thereon a continuous tubular coil of wire, said coil containing an interior binding-wire of less diameter than the opening through the coil, substantially as set forth.

707,612. PAGE-PRINTING TELEGRAPH. GIUSEPPE MUSSO, S. Angelo del Lombardi, Italy. Filed July 3, 1901. Serial No. 67,054. (No model.)

Claim.—1. In a printing-telegraph, the combination with a main line or circuit and transmitting means for producing electrical impulses of different strength therein, of a receiver comprising an armored solenoid rotatably mounted and adapted to take different positions corresponding to the intensity of the impulse or current, a circuit-closing arm operatively connected with said solenoid, and type-writer-operating circuits controlled by the movement of said arm, substantially as described.



2. In a printing-telegraph, the combination with a main line or circuit and transmitting means for producing electrical impulses of different strength therein, of a receiver comprising an electromagnet included in said circuit, a solenoid rotatably mounted in proximity thereto and designed to be operated according to the strength of the electrical impulse, a contact-carrying arm operatively connected with said solenoid, type-writer-operating circuits controlled by said arm, an auxiliary circuit and battery, and means operated by the initial current on the main line for connecting said auxiliary circuit with the magnet, substantially as described.

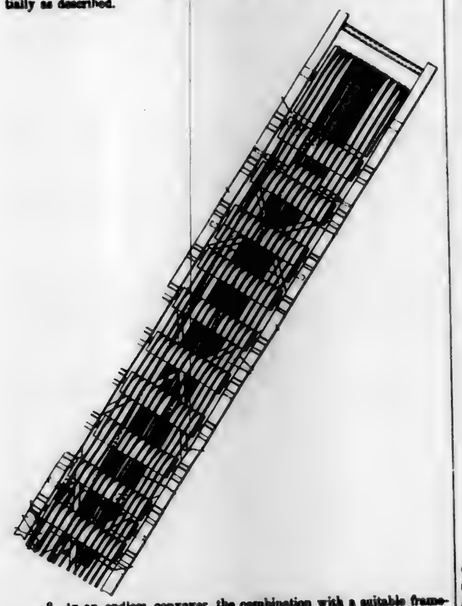
3. In a printing-telegraph, the combination with a main line or circuit and transmitting means for producing electrical impulses of different strength therein, of a receiver comprising an electromagnet included in said circuit, a solenoid rotatably mounted in proximity thereto and designed to be operated according to the strength of the electrical impulse, a contact-carrying arm operatively connected with said solenoid, type-writer-operating circuits controlled by said arm, an auxiliary circuit and battery, and means controlled by the initial current in said main line for reversing the flow of current through said magnet and reinforcing it by said auxiliary battery, substantially as described.

4. The combination with the main line of a combined transmitter and receiver comprising a plurality of keyboard-controlled contacts, variable resistances interposed between said contacts and the line, an electromagnet 66 having electrical connection with the line, current-reversing means included in said connections, an electromagnet 38 for operating reversing means, means controlled by the initial current on the main line for energizing said magnet 38, type-writer-controlling circuits and means whereby the varying impulses in said magnet 66 operates said controlling circuits substantially as described.

707,618. ENDLESS CONVEYER. WILLIAM I. MCCABE, Seattle, Wash. Filed Nov. 21, 1901. Serial No. 83,207. (No model.)

Claim.—1. An endless conveyer, comprising a suitable framework, a single cable carried thereby, pulleys at either end of said framework, the said cable being wound a number of times about said pulleys and forming a continuous carrier-belt, a similar cable forming a belt and interlacing with said first-mentioned cable on one of its pulleys, and means for imparting motion to said interlacing cable, substantially as described.

2. In an endless conveyer, the combination with a suitable framework, of a circumferentially-grooved pulley mounted at each end of said framework, one of said pulleys having a greater number of circumferential grooves than the other, a series of strands of cable passed over and moving within the grooves of said pulleys, a belt composed of a number of strands of cable passed about and operating within some of the circumferential grooves in one of said pulleys and interlacing with said first-mentioned cable, substantially as described.



3. In an endless conveyer, the combination with a suitable framework, of a circumferentially-grooved pulley mounted at each end of said framework, a continuous cable passed over said pulleys, a circumferentially-grooved pulley mounted within said framework, means for imparting motion thereto, and a continuous cable moving within the grooves of said last-mentioned pulley and passed about and operating within circumferential grooves in one of said end pulleys and interlacing with said first-mentioned cable, substantially as described.

4. In an endless conveyer, the combination with a suitable framework, of a pulley mounted at one end thereof and provided with a plurality of circumferential grooves, a pulley mounted at the opposite end of said framework and provided with similar grooves on the same vertical plane, and also provided with a plurality of similar grooves spaced between said first-mentioned grooves, a continuous carrier-belt carried by said pulleys and formed of a single cable moving within the grooves of said pulleys on the same plane, and a second belt formed of a single cable moving within said second-mentioned grooves, and means for imparting motion to said second-mentioned belt, substantially as described.

706,614. DRIVING MECHANISM FOR PORTABLE ELECTRIC CONVEYERS. WILLIAM I. MCCABE, Tacoma, Wash. Filed Dec. 17, 1901. Serial No. 86,201. (No model.)

Claim.—1. A portable conveyer comprising a suitable frame, an endless conveyer-belt mounted upon the same, a driving-drum mounted within said frame transversely thereof, a tension-drum also mounted transversely of the frame within the same, and spaced from said driving-drum longitudinally of the frame, the said belt being passed over one end of the frame, over the driving-drum and then lapped upon itself in an opposite direction to that of its general movement, and passed over the tension-drum, and then passed in the direction of its general movement to the opposite end of the frame, and means for moving said tension-drum bodily longitudinally of said frame, substantially as described.

2. A portable conveyer comprising a suitable frame, an endless belt mounted thereon, means for driving said belt, a pulley mounted in said frame and engaging a portion of said belt for directing the same in opposite direction to that of its general movement, and means for adjusting said last-mentioned pulley longitudinally of said frame for increasing or decreasing the distance of said movement, whereby the tension of said belt may be governed, substantially as described.

3. A portable conveyer comprising a suitable frame, an endless conveying-belt, pulleys for supporting the belt on the frame, an actuating-drum and a tension-drum also engaging the said belt at a point near the center of the conveyer-frame, a motor mounted centrally in the said frame and geared directly to the actuating-drum whereby the device is well balanced, substantially as described.

4. In a portable conveyer, the combination with a frame and an endless conveyer-belt, of an actuating-pulley and a tension-pulley engaging said belt, bearing-boxes engaging the journals of said tension-pulley, the said bearing-boxes being mounted in the frame, slidable longitudinally thereof and bolts secured to said boxes for adjusting the same longitudinally of the frame, whereby the tension of the belt may be controlled, substantially as described.

5. A portable conveyer comprising a suitable frame, an endless conveyer-belt mounted thereon, a driving-drum actuating said belt, means for driving said drum, a tension-drum engaging said belt, journal-boxes slidably mounted in said frame, and carrying the journals of said tension-drum, and means for adjusting said journal-boxes for moving said tension-drum, substantially as described.

707,615. CUFF-HOLDER. SPENCER MCCAY, Topeka, Kans. Filed Dec. 30, 1901. Serial No. 87,793. (No model.)

Claim.—1. In combination, a member having a jaw extended therefrom at about a right angle, a second member movable toward and from the first-mentioned member and having a part projected therefrom at approximately a right angle and comprising an inclined portion and a jaw, the said inclined portion riding upon a part of the first-described member to effect an opening and a closing of the jaws in a direction at a right angle to the plane of movement of the said members, substantially as described.

2. In combination, a member having a jaw extended therefrom at about a right angle, and a second member movable toward and from the first-mentioned member and having a part projected therefrom at approximately a right angle and comprising an inclined portion, a jaw and a stop between said inclined part and jaw, the said inclined portion riding upon a part of the first-mentioned member to effect an opening and a closing of the jaws in a direction at a right angle to the plane of movement of the said members and the said stop limiting the outward movement of the members when the jaws are closed, substantially as specified.

3. In combination, a member having a jaw, extended therefrom at about a right angle, and a second member movable toward and from the first-mentioned member and having a part projected therefrom at approximately a right angle and comprising an inclined portion, an oppositely-inclined jaw and a crimp between the said inclined part and jaw to form a stop for limiting the outward movement of the said members, the jaws

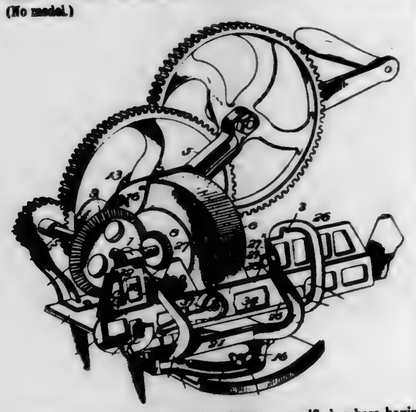
opening and closing in a direction at a right angle to the plane of movement of the said members by the inclined part riding upon the first-mentioned member when the said members are moved laterally, substantially as set forth.

4. In combination, a member having a jaw extended therefrom at about a right angle, and having a guide in line with said jaw, and a second member movable toward and from the aforementioned member and having a part projected therefrom at approximately a right angle and comprising a jaw and an inclined part, the latter adapted to operate in the guide to effect an opening and a closing of the jaws in a plane at a right angle to the plane of movement of the said members, substantially as specified.

5. In combination, a member having a jaw extended therefrom at about a right angle and composed of spaced parts, and having an eye in line with the space between the parts of the jaw to form a guide, and a second member having a part projected therefrom at approximately a right angle and comprising a jaw to enter the space between the parts of the first-mentioned jaw and an inclined portion mounted in the said guide and adapted to effect an opening and a closing of the jaws in a direction at a right angle to the plane of movement of the members, substantially as described.

6. A cuff-holder constructed of a single length of wire and comprising a button for engagement with the cuff, spring members, a jaw and guide at the end of one of the said members, oppositely-inclined parts at the end of the other member, one of said inclined parts constituting a jaw and the other mounted to reciprocate in the said guide to effect an opening and a closing of the jaws by a lateral movement of the members, and a crimp between the said oppositely-inclined parts to form a stop, substantially as set forth.

707,616. SHARPENER FOR MOWER OR REAPER KNIVES. SPENCER MCCAY, Topeka, Kans. Filed Jan. 10, 1902. Serial No. 89,192. (No model.)



Claim.—1. In a machine of the character specified, a base having lugs, a swinging frame comprising arms and a connecting tie-bar, the latter having extensions forming journals mounted in the aforesaid lugs, and a clamp carried by the swinging frame, substantially as set forth.

2. In a machine of the character described, a clamp for the work comprising a frame, spaced jaws coöperating with the frame, and means for simultaneously operating both jaws to effect a gripping of the work, substantially as set forth.

3. In a machine of the character described, a clamp for the work comprising a frame, spaced jaws coöperating with the frame, a tie connecting the jaws, and means for applying force to the said tie to effect a simultaneous operation of the jaws, substantially as set forth.

4. In a machine of the type specified, a clamp for the work comprising a frame, spaced jaws coöperating with the frame for gripping the work, a spring-tie connected to the jaws for simultaneous operation, and means for applying pressure to the spring-tie, substantially as and for the purpose set forth.

5. In a machine of the character described, a clamp for the work comprising a frame, spaced jaws, a tie having loose connection with each of the jaws to effect simultaneous movement thereof and permit each to adapt itself to any variation in thickness of the work to be clamped, and means for applying pressure to the said tie, substantially as set forth.

6. In a machine of the character described, a clamp comprising a frame, spaced jaws coöperating with the frame, a rod or bar having its ends seated in notches or depressions of the said jaws, and means for applying force to the said tie to effect simultaneous actuation of the jaws, substantially as set forth.

7. In a clamp, a frame, spaced jaws having pivotal connection with the frame and comprising elbow-shaped portions and having seats in the elbows closed at their outer ends by reinforcing-plates, a tie rod or bar having its ends fitted in said seats, and means for applying pressure to the said tie to effect simultaneous movement of the jaws, substantially as set forth.

8. In a clamp, a frame having slots, spaced jaws having a portion passed through the said slots and notched to make pivotal connection therewith, a tie rod or bar connecting the jaws, and means for applying pressure to said tie, substantially as specified.

9. In a clamp, a frame, spaced jaws pivotally mounted upon the frame, a tie rod or bar connecting said jaws, and a cam-lever pivotally attached to the frame and adapted to exert a pressure upon the tie-rod intermediate of its ends, substantially as set forth.

10. In a grinding-machine, and in combination with the bed provided with a rotary grinder, a base mounted upon the bed for angular adjustment, means for securing the base in the required position, a swinging frame mounted upon the base, and a clamp having adjustable pivotal connection with the swinging frame and having its upper portion cut away intermediate of its ends, substantially as and for the purpose set forth.

707,617. TARGET. JOHN L. MCCULLOUGH, Brooklyn, N. Y. Filed June 15, 1901. Serial No. 64,635. (No model.)

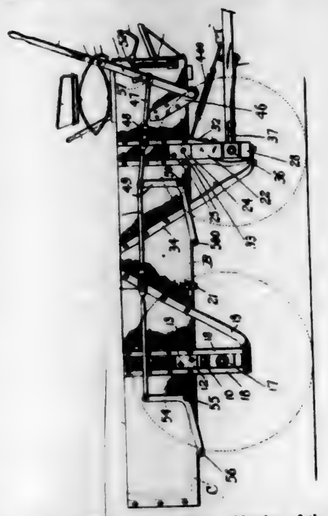
Claim.—1. A target for a target apparatus having a face-plate, a movable indicator adapted to move in and out from behind said plate, a lever which actuates said indicator, means for holding said indicator out of sight, normally, behind said face-plate, and an electromagnet which moves the lever in the direction to expose said indicator to view, substantially as set forth.

2. A target having superposed plates with spaces between them, an electromagnet, its armature, its armature-lever, its spring, and a disk carried by said armature-lever and adapted to move into and out of view in a space between said plates by the movements of said lever and its spring, substantially as set forth.

3. A target having a face-plate, a movable disk adapted to move in and out from behind said plate, a lever which actuates said disk, a spring which moves said lever in one direction, and an electromagnet which moves it in the opposite direction, substantially as set forth.

4. A target for a target apparatus comprising the superposed and separated face-plates 11, 12 and 13, a frame supporting same, electromagnets mounted in the frame back of said plates, the armatures, armature-levers of said magnets, the springs of said levers, and indicators carried by the respective armature-levers and held normally behind the respective face-plates by said springs and the electromagnets adapted to move the indicators into view, substantially as set forth.

707,618. DUMPING-WAGON. WILLIAM MCINTOSH, Clinton, Mass. Filed Dec. 21, 1901. Serial No. 86,748. (No model.)



Claim.—1. In a dumping-wagon, the combination of the wagon-body, front and rear axles rigidly secured thereto without a reach or intermediate connection, and a dumping-board pivoted on each axle construction.

2. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto without a reach or intermediate connection, axle-blocks pivoted to the front axle, and a dumping-board pivoted on each axle construction.

3. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto, axle-blocks pivoted to the ends of the front axle, a pole pivoted to the front axle and connected to operate the axle-blocks, and a dumping-board pivoted on each axle construction.

4. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto, axle-blocks pivoted to the front axle, arms extending from said axle-blocks, a pole pivoted to the front axle, connections from the pole to the axle-blocks, and a dumping-board pivoted on each axle construction.

5. In a dumping-wagon, the combination of the wagon-body, a rocker-bolster connected thereto, a rear axle supporting said rocker-bolster, a front-axle construction comprising a bolster secured to the wagon-body, and a dumping-board pivoted on each of said bolsters.

6. In a dumping-wagon, the combination of the wagon-body, a rocker-bolster secured thereto, a rear axle supporting said rocker-bolster braces extending down from the wagon-body on each side of the rear axle, a front-axle construction, and a dumping-board pivoted on each axle construction.

7. In a dumping-wagon, the combination of the wagon-body, a rocker-bolster secured thereto, a rear axle supporting said rocker-bolster, rods extending down from said wagon-body and bearing on each side of said rear axle, a brace-bar connected to the ends of said rods and to the wagon-body, a front-axle construction, and a dumping-board pivoted on each of said axle constructions.

8. In a dumping-wagon, the combination of the wagon-body, a rear axle construction, a front-axle construction comprising a bolster, a supplemental bolster, blocks separating said bolster and said supplemental bolster, a pole connected to said bolsters, axle-blocks pivoted between the ends of said bolster and said supplemental bolster, connections from the same to the pole, and a dumping-board pivoted on each axle construction.

9. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto without a reach or intermediate connection, a dumping-board pivoted on each axle, a lever pivoted on the wagon-body, bell-crank levers connected to operate the dumping-boards, and connections from the lever to operate the bell-crank levers.

10. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto without a reach or intermediate connection, a dumping-board pivoted on each axle, a shaft mounted in brackets secured to the wagon-body, a handle or operating-lever on said shaft, bell-crank levers pivoted to each side of the wagon-body, rods connected thereto to support the rear ends of the dumping-boards, a handle on said shaft, and connections therefrom to said bell-crank levers, a lever on the other end of the shaft, and connections therefrom to the other set of bell-crank levers.

11. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto without a reach or intermediate connection, a dumping-board pivoted on each axle, a shaft mounted in brackets secured to the wagon-body, a handle or operating-lever on said shaft, bell-crank levers pivoted to the sides of the wagon-body, and having rods supporting the rear ends of the dumping-boards, a handle on said shaft, connections to said bell-crank levers, and a catch for holding said handle in position to keep the dumping-boards in horizontal position.

12. In a dumping-wagon, the combination of the wagon-body, front and rear axles secured thereto, dumping-boards pivoted on said axles, an operating-handle made in two sections pivoted together, a locking-pin for locking the two sections of the handle together, and connections from the handle to the dumping-boards.

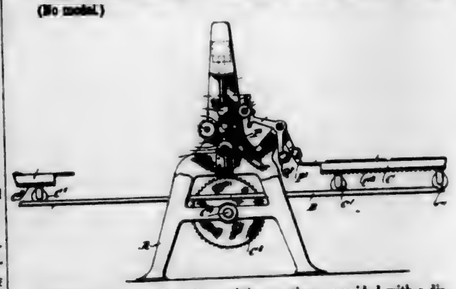
707,619. HERNIAL TRUSS. JOSEPH H. MCKAGUE, Columbia Heights, Minn. Filed Mar. 24, 1902. Serial No. 99,653. (No model.)

Claim.—1. The combination with a truss-pad having an oblong opening in its body, of a plate secured to one side of the pad and covering the opening, a screw adapted to turn in said plate without moving axially, and an oblong auxiliary pad in said opening provided with a tapped socket to receive the screw, whereby the auxiliary pad may be adjusted axially toward or away from the main pad, substantially as set forth.

2. The combination with an oblong truss-pad having an oblong opening in its body and having one of its surfaces flat and the other rounded and tapering from thicker middle and lower portions to thinner and narrower upper portions, of a plate secured to said flat surface and covering said opening, a screw adapted to turn in said plate without moving axially, and an oblong auxiliary pad in said opening provided with a tapped socket to receive the screw, whereby the auxiliary pad may be adjusted axially toward or away from the main pad, substantially as set forth.

3. The combination with a pad-plate, of an oblong pad adjustably secured thereon and having its contact-surface flat and its other surface rounded and tapering from thicker middle and lower portions to thinner and narrower upper portions and having an opening in its body, a plate secured to said flat surface and covering said opening, a screw adapted to turn in said plate without moving axially, and an oblong auxiliary pad in said opening provided with a tapped socket to receive the screw, substantially as set forth.

707,620. MACHINE FOR APPLYING COATINGS. JOSEPH B. MCKEOWN, Union Hill, N. J. Filed Oct. 18, 1901. Serial No. 79,166. (No model.)



Claim.—1. A machine for applying coatings, provided with a distributer for the coating material, a coating-material supply for the said distributer, a fluid-pressure supply connected with the said distributer for forcing the coating material under pressure out of the distributer onto the surface to be coated, and means for alternately connecting the said coating-material supply and the said fluid-pressure supply with the said distributer, as set forth.

2. A machine for applying coatings, provided with a distributer for the coating material, a coating-material supply for the said distributer, a fluid-pressure supply connected with the said distributer, for forcing the coating material under pressure out of the distributer onto the surface to be coated, means for alternately connecting the said coating-material supply and the said fluid-pressure supply with the said distributer, a table for

carrying the surfaces to be coated, and means for moving the table past the said distributer at a uniform rate of speed, as set forth.

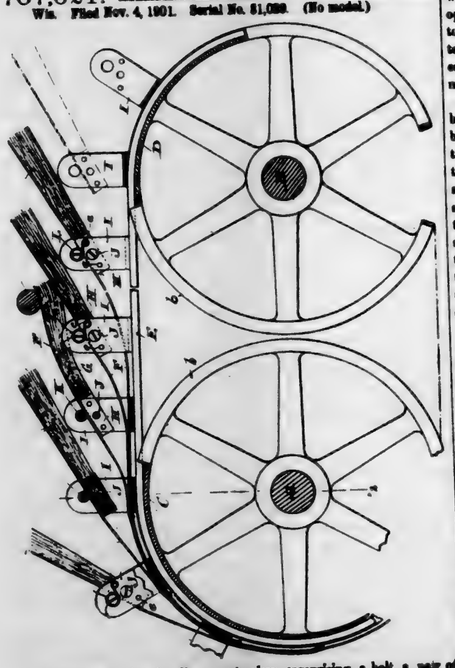
3. A machine for applying coatings, comprising a table mounted to travel and adapted to carry the surfaces to be coated, means for moving the table, a distributer extending over the table at an angle to the line of movement of the table, the distributer having discharge-openings for the coating material to pass from the distributer onto the surfaces to be coated, a coating-material supply connected with the said distributer, and a pressure-supply for forcing the material out of the distributer by pressure, as set forth.

4. A machine for applying coatings, comprising a table mounted to travel and adapted to carry the surfaces to be coated, means for moving the table, a distributer extending over the table at an angle to the line of movement of the table, the distributer having discharge-openings for the coating material to pass from the distributer onto the surfaces to be coated, a coating-material supply connected with the said distributer, a pressure-supply for forcing the material out of the distributer by pressure, and beating means in the said distributer, as set forth.

5. A machine for applying coatings, comprising a table mounted to travel and adapted to carry the surfaces to be coated, means for moving the table, a distributer extending over the table at an angle to the line of movement of the table, the distributer having discharge-openings for the coating material to pass from the distributer onto the surfaces to be coated, a coating-material supply connected with the said distributer, a pressure-supply for forcing the material out of the distributer by pressure, and means for controlling the coating-material supply and the said pressure-supply, as set forth.

6. A machine for applying coatings, comprising a table mounted to travel and adapted to carry the surfaces to be coated, means for moving the table, a distributer extending over the table at an angle to the line of movement of the table, the distributer having discharge-openings for the coating material to pass from the distributer onto the surfaces to be coated, a coating-material supply connected with the said distributer, a pressure-supply for forcing the material out of the distributer by pressure, and means for alternately connecting the said coating-material supply and the said pressure-supply with the said distributer, as set forth.

707,621. ABRADING MECHANISM. JOHN M. NASH, Milwaukee, Wis. Filed Nov. 4, 1901. Serial No. 81,089. (No model.)



Claim.—1. An abrading mechanism comprising a belt, a pair of pulleys on which the belt is run, and flexible-backed abrading material carried with said belt to extend tangentially from the same at intervals thereof.

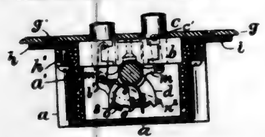
2. An abrading mechanism comprising a belt, a pair of pulleys on which the belt is run, strips of abrading material carried with said belt, brushes that being rigid with the aforesaid belt at intervals of the same tangent thereto constitute flexible backings for the abrading-strips, and means for clamping said strips against the brush-butts.

3. An abrading mechanism comprising a belt, a pair of pulleys on which the belt is run, brackets rigid on the outer face of said belt at intervals of the same, brushes fast in the brackets tangent to the belt, abrading-strips carried with the aforesaid belt in opposition to the brushes, and means for clamping the strips against the brush-butts.

4. An abrading mechanism comprising a belt run on pulleys, brackets rigid on the outer face of the belt at intervals of the same, brushes fast in the brackets tangent to said belt, abrading-strips carried with the aforesaid belt in opposition to the brushes, and spring-controlled rotarily-adjustable cam-rods mounted in the brackets to clamp said strips against the brush-butts.

5. An abrading mechanism comprising a belt run on pulleys, brackets rigid on the outer face of the belt at intervals of the same, brushes bolted in the brackets, bracket-pins on inclined planes in opposite directions from the brush-bolts engaging brush-butt apertures, abrading-strips carried by said belt, and means for clamping the strips against the brush-butts.

707,622. SNAP PUSH-BUTTON SWITCH. WILLIAM J. NEWTON, New York, N. Y., assignor to Frank M. Dyer, New York, N. Y. Filed Oct. 17, 1901. Serial No. 79,087. (No model.)



Claim.—1. In a snap push-button switch having a spindle with contact-arms insulated upon its opposite ends and an operating-lever pivoted to turn upon the spindle, of a locking device for the spindle comprising a segmental plate secured to the spindle and having a curved slot with notches at its opposite ends, a spring placed under tension by the operating-lever to turn the spindle, and a locking-plate pivoted adjacent to the segmental plate and provided with studs to engage the notches alternately, and having its ends projected in line with the ends of the operating-lever to be moved alternately thereby, and thus release the segmental plate and spindle while under the spring-pressure.

2. In a snap push-button switch, the combination, with two push-buttons and their guide-block, of a post supported upon such guide-block between the buttons, a spindle fitted to turn in the post and having contact-arms insulated upon its opposite ends, an operating-lever fitted to turn upon the spindle with the push-buttons connected to its ends, and an arm projected from one side of such lever with a lug to engage a spring, a spring wound around the spindle with one of its ends applied to the lug on the arm, a segmental plate attached to the spindle with a curved slot having notches at its opposite ends, and having a lug to engage with the other end of the spring, and a locking-plate pivoted upon the post next the segmental plate and provided with studs to engage the notches alternately, and having its ends projected in line with the ends of the operating-lever to be moved alternately thereby.

3. In a snap push-button switch, the combination, with two push-buttons and their guide-block, of a thin post supported upon such guide-block between the buttons, a spindle fitted to turn in the post with contact-arms insulated upon its opposite ends, an operating-lever fitted to turn upon the spindle and having the push-buttons connected to its opposite ends, and an arm projected from one side of such lever with a lug to engage a spring, a barrel upon the spindle with a spring wound around the same and one of its ends applied to such lug, a segmental plate attached to the spindle with a curved slot having notches at its opposite ends and a lug to engage one end of the spring, and a locking-plate pivoted upon the post next the segmental plate and provided with studs to engage the notches alternately, and having its ends projected in line with the ends of the operating-lever to be moved alternately thereby.

4. In a snap push-button switch, the combination, with two push-buttons and their guide-block, of the thin flat post supported upon such guide-block between the buttons, the spindle *j* fitted to turn in the post with insulating-hubs upon its opposite ends and contact-arms mounted thereon, the operating-lever *m* fitted to turn upon the spindle next the post and having the push-buttons connected to its opposite ends, and having the arm upon its outer side with the stud *o'* projected over the spindle, the barrel upon the spindle adjacent to such stud with spring *s* wound around the same and one end applied to the stud *o'*, the segmental plate *l'* attached to the spindle upon the opposite side of the post and formed

with a curved slot having notches at its opposite ends and having a lug *o* projected over the end of the post adjacent to the lug *o'* and engaged with the opposite end of the spring *s*, the locking-plate *n* pivoted upon the post between the segmental plate and post, the spring *t* extended around the spindle with pins *t'* upon the segmental plate to hold the ends of the spring against the locking-plate, and studs upon the locking-plate to engage the notches of the segmental plate alternately, with the ends of the locking-plate bent to project past the post in line with the ends of the operating-lever, substantially as herein set forth.

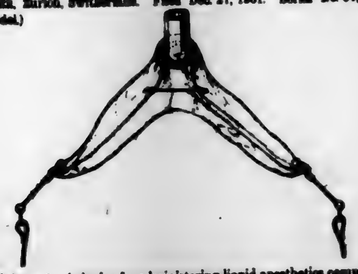
5. In a snap push-button switch, the combination, with two push-buttons, of a guide-block perforated for the movement of the same, a post supported upon the guide-block, the spindle *j* fitted to turn in the post with insulating-hubs *j'* upon its opposite ends and contact-arms mounted thereon with extension-plates *k'* at one side of the same, the contact-springs *f* supported upon two corners of the block to constantly engage such extension-plates, and the contact-springs *f'* supported upon the opposite corners of the block, and means connected with the push-buttons for turning the spindle to move the contact-arms to and from the contact-springs *f'*.

6. In a snap push-button switch, the combination, with two push-buttons, of an insulating guide-block *b* perforated for the movement of the same, a post supported upon the guide-block, the spindle *j* fitted to turn in the post with insulating-hubs *j'* upon its opposite ends and contact-arms *k* mounted thereon with segmental wings *k'* at one side of each the double spring-contacts *f* supported upon two corners of the block to constantly engage such segmental wings, the contact-springs *f'* supported upon the opposite corners of the block, means connected with the push-buttons for turning the spindle to move the contact-arms to and from the contact-springs *f'*, spring-plates *e'* clamped by the feet of the contact-springs *f* and *f'* at the four corners of the block, and a casing *a* having a recess upon the front to receive the guide-block, and binding-posts in its four corners with spring-plates *e* projected therefrom to contact with the spring-plates upon the switch when the switch is inserted in the casing.

7. In a snap push-button switch, the combination, with the guide-block having the switch mechanism mounted wholly thereon, and having spring-contacts with spring-plates *e'* projected therefrom as set forth, of the casing having a cavity upon the front to receive the guide-block, and recesses in its four corners with passages for the conductor leading thereto, binding-posts secured in such recesses with spring-plates *e* projected therefrom to contact with the spring-plates upon the switch, such binding-posts having each a grooved seat therein with grooved gib or block fitted over the seat and passage, and into contact with the end of the recess, and a set-screw to press the gib toward the seat to clamp the conductor thereon, whereby the conductors may be pushed automatically into the binding-posts from the passages when the set-screws are slackened, substantially as herein set forth.

8. In a snap push-button switch, the combination, with the metallic casing *a* having recess *a'* adapted to wholly inclose the switch, of the insulating guide-block *b* forming the base of the switch and fitted detachably to such recess and having the switch mechanism supported thereon, the push-buttons *c* extended through the guide-block and formed each with the chamber extended from its inner end beyond the middle of its length with pivot *c'* across its inner end, the links *m* extended into the chamber and jointed upon such pivots, and the switch mechanism having an operating-arm attached to the opposite ends of the links, and provided with spindle close to the insulating guide-block, whereby the operating-arm may be pivoted close to the guide-block and vibrated by the alternate movement of the push-buttons, and the link carried wholly within the guide-block and the push-button when the push-button is protruded, substantially as herein set forth.

707,623. ELASTIC ANESTHETIC APPARATUS. HERMANN HIRSIGER, Zurich, Switzerland. Filed Dec. 27, 1901. Serial No. 87,495. (Model.)



Claim.—1. A device for administering liquid anesthetics comprising layers of textile material secured at their edges forming a pocket or space within and having a small opening at one edge, spring-wire means within the pocket for stiffening and shaping the same, and means for securing the device to the head of the patient, substantially as described.

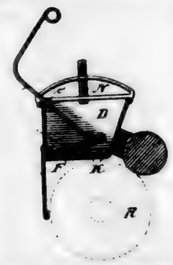
2. A device for administering liquid anesthetics comprising layers of textile material secured at their edges forming a pocket or space within and having a small opening at one edge, spring-wire means within the pocket for stiffening and shaping the same, means for drawing together the two lateral wings of the device, and means for securing the device to the head of the patient, substantially as described.

707,624. TOOTH-FASTENER FOR WEEDERS. GEORGE A. HILES, Utica, N. Y., assignor to Standard Harrow Company, Utica, N. Y. Filed June 25, 1902. Serial No. 113,623. (No model.)

Claim.—1. The combination in a tooth-fastener of an angle-bar, a tooth having a horizontal, U-shaped bend at its attaching end, the fastener adapted to be applied on the inside of the angle-bar, having a recess opening toward the top to receive the U-shaped end of the tooth and a bolt passing through the fastener, the bend of the tooth and the flange of the angle-bar, substantially as set forth.

2. The combination of the angle-bar, the tooth having the hook-bend on the shank, the fastener having the side walls 2^a, 2^a, and the projection 3^a and the bolt passing through the fastener, the bend of the tooth and the flange of the angle-bar, substantially as set forth.

707,625. INK-FOUNTAIN FOR PRINTING-PRESSES. WILS HILSON, San Francisco, Cal. Filed Apr. 10, 1901. Serial No. 55,265. (No model.)



Claim.—1. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges in its bottom, the hinged valved plate in the bottom of the receptacle and controlling the supply of ink to the discharges, the handle by which the valve-plate is lifted to an inclination with the bottom, and means for adjustably locking said handle to hold the valve-plate at different inclinations.

2. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges in its bottom, the freely-swinging spreading-roller carried by the ink-receptacle on one side and the guard-plate depending from said receptacle on the other side.

3. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges in its bottom, the adjustable valve-plate within the ink-receptacle for controlling the supply of ink to the discharges, the freely-swinging spreading-roller carried by the ink-receptacle on one side and the guard-plate depending from said receptacle on the other side.

4. In an ink-fountain for printing-presses, the combination of the ink-receptacle having suitable discharges, fixed hangers, screw-studs adjustably fitted to the receptacle and passing freely through the hangers, and springs encircling the screw-studs whereby the receptacle is adjustably and yieldingly suspended.

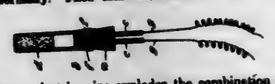
5. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges, the freely-swinging spreading-roller carried by the receptacle on one side, the guard-plate depending from the receptacle on the other side, fixed hangers, and adjustable suspending devices connecting the receptacle with the hangers, for regulating the height of the receptacle relatively to the part to be inked.

6. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges, the freely-swinging spreading-roller carried by the receptacle on one side, the guard-plate depending from the receptacle on the other side, fixed hangers, and spring-controlled adjustable suspending devices yieldingly connecting the receptacle with the hangers, for regulating the height of the receptacle relatively to the part to be inked

7. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges in its bottom, the adjustable valve-plate within said receptacle for controlling the supply of ink to the discharges, the spreading-roller swung from one side of the ink-receptacle, the guard-plate depending from its other side, fixed hangers, and adjustable suspending devices connecting the ink-receptacle with the hangers for regulating the height of the receptacle relatively to the part to be inked.

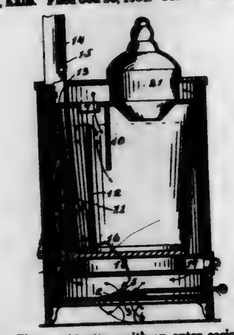
8. In an ink-fountain for printing-presses, the combination of the ink-receptacle having discharges in its bottom, the adjustable valve-plate within said receptacle for controlling the supply of ink to the discharges, the spreading-roller swung from one side of the ink-receptacle, the guard-plate depending from its other side, fixed hangers, and spring-controlled adjustable suspending devices yieldingly connecting the ink-receptacle with the hangers for regulating the height of the receptacle relatively to the part to be inked.

707,626. ELECTRIC MINE-EXPLODER. WILHELM HOEBER, Schalke, Germany. Filed Mar. 22, 1902. Serial No. 100,455. (No model.)



Claim.—In an electric mine-exploder the combination with a conical firing-stopper *a* containing the fuse composition, of metal pipe *c* fixed within the said stopper, conducting-wires *g* inserted into the said metal pipes, and an explosive-shell having a splitted open edge by means of which the said shell is simply set upon the conical firing-stopper *a*, substantially as described.

707,627. APPARATUS FOR COMBUSTION OF FUEL. CHRISTIAN OLSTED, Wyandotte county, Kans., assignor to Edward Haven, Kansas City, Kans. Filed Oct. 26, 1901. Serial No. 80,078. (No model.)



Claim.—1. The combination with an outer casing provided in the lower end with a draft-opening, of an inner casing provided at its lower end with an ash-receiving chamber, having a discharge-passage leading through the outer casing, a closure for said discharge-opening, a grate in the inner casing above the ash-receiving chamber, a fuel-passage leading through the outer and inner casings, an air-inlet and a gas-discharge passage in the upper end of the inner casing, two transverse partitions one on each side of the said air-inlet and extending downward toward the bottom of the inner casing, and a transverse partition located between the said two partitions and extending upward from the bottom of the inner casing to a point below the top thereof and above the lower ends of the said two partitions, substantially as described.

2. The combination with an outer casing provided with a draft-opening, of an inner casing, a fuel-supply passage leading through the two casings, a closure for the said passage, an air-inlet opening in the upper end of the inner casing, and a gas-passage leading past the said air-inlet and thence downward and thence upward to the exterior of the inner casing, substantially as described.

3. The combination with an outer casing provided with a draft-opening, of a register controlling the said draft-opening, an inner casing, a fuel-supply passage leading through the two casings, a closure for the said passage, an air-inlet opening in the upper end of the inner casing, and a gas-passage leading past the said inlet-opening and thence downward and thence upward through the exterior of the inner casing, substantially as described.

4. The combination with an outer casing provided with a draft-inlet opening, of a register controlling the said draft-opening, an inner casing provided in the upper end with an air-inlet and provided at the lower end with a passage for the removal of ashes, an upwardly-extending partition in the inner casing located below the said air-inlet, a horizontal partition located above the said ash-passage and at the lower end of the said partition and having perforations at one side of the said partition but imperforate on the other side thereof, and a gas-passage leading past the upwardly-extending partition and past the said air-inlet and thence downward and thence upward to the exterior of the inner casing, substantially as described.

5. The combination with an outer casing provided with a draft-inlet opening, of a register controlling the said inlet-opening, an inner casing having two chambers and an air-inlet discharging into both chambers, an opening connecting the two chambers adjacent to the air-inlet, a discharge-opening leading from one of the chambers, and two partitions, one in each chamber extending downward from the upper end of the casing below the opening connecting the two chambers, substantially as described.

6. The combination with an outer casing provided with a draft-inlet opening, of an inner casing provided with two chambers, an opening connecting the two chambers, an air-inlet opening discharging into the two chambers across the said connecting-opening, a discharge-opening leading through the inner casing from one of the chambers, the chamber having the discharge-opening being provided with an imperforate bottom and the other chamber having a perforated bottom, a closed ash-receiving chamber located below the perforated bottom of the said chamber and provided with a passage for the discharge of ashes, and a closure for the said ash-discharge passage, substantially as described.

7. The combination with an outer casing provided with a draft-inlet opening, of a register controlling the said opening, an inner casing provided with two chambers, an opening connecting the two chambers, an air-inlet discharging into the said connecting-opening, a fuel-supply opening leading through the inner casing into one of the said chambers, a discharge-opening leading through the inner casing from the other chamber, the chamber having the discharge-opening being provided with an imperforate bottom, the chamber having the fuel-supply passage being provided with a perforated bottom, an ash-receiving chamber placed so as to receive ashes through the said perforations and having an ash-discharge passage leading therefrom, a closure for the said ash-discharge passage, and a closure for the fuel-supply passage, substantially as described.

8. The combination with a casing provided with two chambers having an opening connecting them, two partitions, one in each chamber, extending downward from the upper end of the casing past the said connecting-opening, an air-inlet between the said two partitions, an outlet-opening leading from one of said chambers, the chamber having the outlet-opening being provided with an imperforate bottom and the other chamber having a perforated bottom, of an ash-receiving chamber located below the perforated bottom of the said chamber and having an ash-discharge opening leading therefrom, substantially as described.

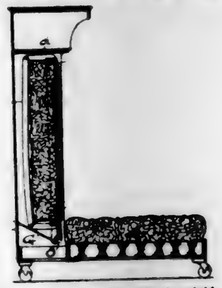
9. A combustion-chamber provided with an air-inlet opening in the upper end, two downwardly-extending partitions located one on each side of the said air-inlet opening, a partition extending upwardly from the bottom of the chamber, between the said two partitions and above the lower ends thereof, and a discharge-opening in the upper end of the casing, substantially as described.

10. A combustion-chamber comprising a casing provided with two downwardly-extending partitions, an air-inlet in the casing between the two said partitions, an upwardly-extending partition located between the two downwardly-extending partitions and extending from the bottom of the chamber above the lower ends of the said two partitions, and a discharge-opening in the upper end of the casing, the bottom of the chamber at one side of the upwardly-extending partition being perforated and imperforate upon the other side thereof, substantially as described.

11. A combustion-chamber provided with an inlet-opening for air in its upper end, a gas-discharge opening also in its upper end, a partition extending downwardly from the upper end of the chamber and located between the two said openings, and a partition extending from the bottom of the chamber upwardly above the lower end of the other partition and having its upper end adjacent to the air-inlet opening, substantially as described.

12. A combustion-chamber provided in its upper end with an air-inlet, a damper controlling the said air-inlet, two downwardly-extending partitions located one on each side of the said air-inlet, a partition extending upwardly from the bottom of the said chamber between the two said downwardly-extending partitions and above the lower ends thereof, and a discharge-opening at one side of one of the downwardly-extending partitions, substantially as described.

707,628. COMBINED COUCH AND FOLDING BED. DAVID T. OWEN, Cleveland, Ohio. Filed Aug. 24, 1901. Serial No. 73,168. (No model.)



Claim.—1. In a combined couch and bed, a rigid right-angled couch and bed frame having a fixed couch in the horizontal portion thereof and a mattress pivoted in the upright portion above the plane of the couch and having its bottom upholstered and provided with independent folding supports at its outer edge, whereby the top side of the mattress is adapted for use as a bed and its bottom as a back for the couch, and the bed folds over the couch and is supported, substantially as described.

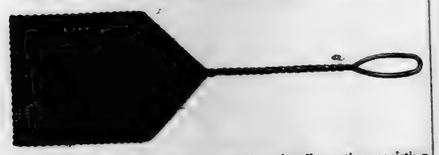
2. A couch and bed frame having a horizontal portion for a couch and an upright portion for a bed, in combination with a bed-mattress having a spring-cushioned top and upholstered bottom and pivoted in said upright portion to be raised and lowered and legs pivoted to its outer edge, and a couch-seat having a fixed rest in the horizontal portion of said frame, whereby the bed is adapted to fold over the couch in use, substantially as described.

3. A combined couch and bed frame having an upright portion for the bed and a horizontal portion for the couch, in combination with a bed-frame adapted to be lowered over the couch, head and foot frames for the bed and mechanism connecting said frames with the bed-frame and constructed to fold said frames when the bed-frame is raised, substantially as described.

4. A rigid right-angled frame for a combined couch and bed, in combination with a folding bed pivoted in said frame and constructed to be lowered over the couch for use as a bed and to be folded up in said frame when out of use as a bed and having its bottom finished to form the back of the couch, head and foot sections of the bed pivoted in said frame and arranged to rest behind the bed when in a raised position, and means to fold said head and foot sections automatically when the bed is folded, substantially as described.

5. The combined couch and bed comprising a bed adapted to be separately folded down over the couch, head and foot frames independently pivoted and mechanism between said frames and said bed to fold and unfold the frames when the bed is raised and lowered, substantially as described.

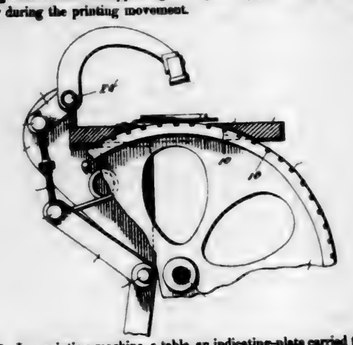
707,629. INSECT-DESTROYER. CHARLES T. FARRIER, Portsmouth, Va. Filed Jan. 3, 1901. Serial No. 41,735. (No model.)



Claim.—An insect-destroyer comprising a handle portion consisting of a wire bent upon itself and having the two members twisted together, the ends of the wire extending outward from the twisted portion at an angle thereto, and a striking portion of wire-gauze rectangular in shape and having the two corners at one end bent over the arms of the handle portion and secured in place, the striking portion being at an angle to the handle portion, substantially as described.

707,680. BILLING-MACHINE. BENJAMIN W. PERKINS, South Bend, Ind. Filed Mar. 10, 1902. Serial No. 97,653. (No model.)

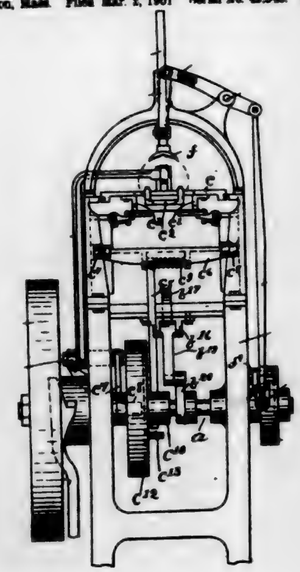
Claim.—1. In a printing-machine, a type-carrier having a type-surface projecting through a table, said table, an indicating-plate mounted on said table, an operating-lever traversing said plate and adapted for engagement therewith at predetermined points, said lever and said carrier being operatively connected to have corresponding movement, a movable platen, a foot-lever, and a toggle connection between said platen and said lever whereby two complete oscillatory movements of the platen will be provided during one complete movement of the foot-lever, whereby the printing-surface and its supporting and operating parts will be held stationary during the printing movement.



2. In a printing-machine, a table, an indicating-plate carried thereby and having semicircular indicating-marks and a concentrically-arranged notched flange, an operating-lever traversing said plate and having a pin adapted to be removably engaged with one of the notches of said plate, a rotating type-carrier having a type-surface projecting through an opening in said table, means for connecting said operating-lever and said type-carrier to provide a coöperating movement therebetween, an impression-arm having a platen, a foot-lever, and a toggle connection between said foot-lever and impression-arm, whereby the printing-surface and its supporting and operating parts will be held stationary during the printing movement.

3. In a printing-machine, a table, an indicating-plate carried thereby and having semicircular indicating-marks and a concentrically-arranged notched flange, an operating-lever traversing said plate and having a pin adapted to be removably engaged with one of the notches of said plate, a rotating type-carrier having a type-surface projecting through an opening in said table, means for connecting said operating-lever and said type-carrier to provide a coöperating movement therebetween, an impression-arm having a platen, a foot-lever, a toggle connection between said foot-lever and impression-arm, and a yielding support and guide for the material to be printed, whereby the printing-surface and its supporting and operating parts will be held stationary during the printing movement.

707,681. BOTTLE-LABELING MACHINE. WILLIAM R. PETTIS, Newton, Mass. Filed Mar. 2, 1901. Serial No. 49,548. (No model.)



Claim.—1. In a bottle-labeling machine, the combination of a label-carrier having a pair of label-carrying shoes, separated to provide a passage between them for the bottle, a pair of yielding label-engaging plates over which the label is brought by said label-carrier, which project beyond the shoes, into the path of movement of the bottle, and which occupy a plane directly beneath a label borne by said label-carrier to thereby impinge the label against the bottle and hold it in correct position thereon while said label is being detached from the label-carrying shoes by a downward movement of the bottle, and which thereafter act as wipers for applying the pasted edges of the label to the bottle, and forward extensions on the frame bearing said label-engaging plates which provide an unobstructed passage for the bottle substantially as described.

2. In a bottle-labeling machine, the combination of a label-holder, a paste-box containing paste-rolls, and a reciprocating label-carrier having a pair of label-carrying shoes, separated to provide a passage between them for the bottle, means for moving said paste-box and label-holder successively toward and from said label-carrier, a pair of pivotally-supported label-engaging plates over which the label is brought by said label-carrier, which project beyond the shoes, into the path of movement of the bottle, and which occupy a plane directly beneath a label borne by said label-carrier, to thereby impinge the label against the bottle and hold it in correct position thereon while said label is being detached from the label-carrying shoes by a downward movement of the bottle, and which thereafter act as wipers for applying the pasted edges of the label to the bottle, and forward extensions on the frame bearing said label-engaging plates which provide an unobstructed passage for the bottle, substantially as described.

3. In a bottle-labeling machine, the combination of a label-carrier having a pair of label-carrying shoes separated to provide a passage between them for the bottle, a pair of pivotally-supported label-engaging plates over which the label is brought by said label-carrier, which project beyond the shoes into the path of movement of the bottle and which occupy a plane directly beneath the label borne by said label-carrier, to thereby impinge the label against the bottle and hold it in correct position thereon while said label is being detached from the label-carrying shoes by a downward movement of the bottle and which thereafter act as wipers for applying the pasted edges of the label to the bottle, and stationary supports for said label-engaging plates constructed and arranged to provide an unobstructed passage for the bottle, substantially as described.

4. In a bottle-labeling machine, a label-carrier, and a pair of label-engaging plates over which the label is brought by said carrier, each label-engaging plate comprising the yielding plate a, pivoted spring-supported frame bearing it, the plate a' to which said frame is pivoted, and the plate a^2 to which said plate a' is adjustably connected to afford adjustment of said label-engaging plates toward and from each other, substantially as described.

5. In a bottle-labeling machine, a label-carrier having a pair of label-carrying shoes, a pair of pivoted label-engaging plates over which the label is brought by said carrier, means for holding said label-engaging plates in horizontal position beneath the label-carrier, and for releasing them whereby they may swing on their pivots into approximately vertical position, substantially as described.

6. In a bottle-labeling machine, a label-carrier having a pair of label-carrying shoes, a pair of pivoted label-engaging plates over which the label is brought by said carrier, springs, movable into and out of engagement with said label-engaging plates, for holding said plates in horizontal position beneath the label-carrier when in engagement therewith and for permitting said label-engaging plates to occupy a position remote from said label-carrier when disengaged therefrom, substantially as described.

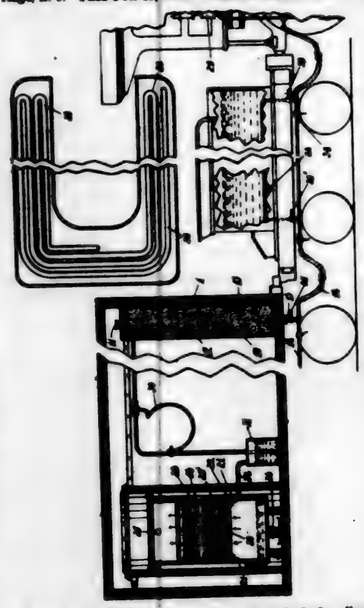
7. In a bottle-labeling machine, a rising-and-falling paste-box, a rocking cross-bar having fingers engaging said paste-box, a lever positively connected to said cross-bar, and means for moving it to in turn move the cross-bar and thereby lift the paste-box, substantially as described.

707,632. BOWLING-ALLEY PIN. ELWOOD G. PHILLIPS, Chicago, Ill., assignor of three-fourths to Charles R. Barrett, Chicago, Ill. Filed May 15, 1902. Serial No. 107,441. (No model.)

Claim.—1. The combination in a bowling-alley pin, of a main body portion having a central cylindrical extension at its lower end and a cylindrical enlargement at the end of such cylindrical extension, and an elastic base formed with a central chamber to receive said cylindrical enlargement and with an annular internal flange at the upper end of said chamber which is adapted to fit the cylindrical extension aforesaid of the main body, substantially as set forth.

2. As an improved article of manufacture, an elastic base for bowling-alley pins formed with a central chamber, an annular internal flange at the upper end of said chamber and a bottom web at the lower end of said chamber which web is provided with a vent-orifice, such base being adapted to have engagement with a central headed shank on the lower end of a bowling-alley pin, substantially as set forth.

707,633. ART OR PROCESS OF LIQUEFYING AIR OR OTHER GASES AND COOLING BY MEANS THEREOF. JAMES F. PLAGE, Glenridge, N. J. Filed Feb. 15, 1901. Serial No. 47,468. (No model.)

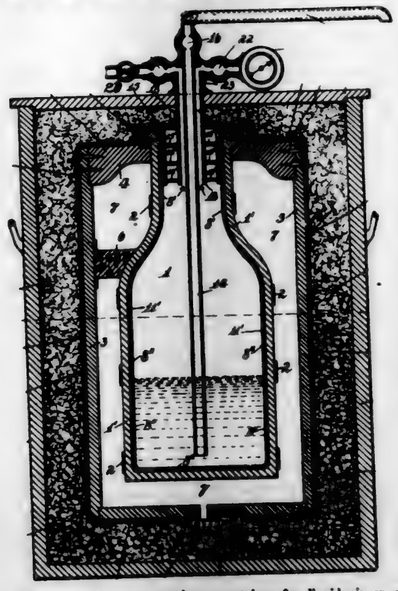


Claim.—1. The art or process herein described of cooling by liquid air or other liquid gas which consists in delivering to the space to be cooled a supply of dry cold gas evaporating from an initial charge of liquid air or other liquid gas, and allowing said evaporated gas to subsequently escape from the said space to be cooled, and subjecting compressed air or other compressed gas to the cooling action of said dry cold evaporated gas in successive counter-currents—the first carrying the dry evaporated liquid air or other gas after it has been delivered to the space to be cooled and before or during the time it is allowed to escape therefrom; and the second carrying said dry cold evaporated liquid air or other gas before its delivery to the space to be cooled; and then conducting during the process said cooled compressed air or other compressed gas to and subjecting the same to the cooling action of said initial charge or a replenished charge of liquid air or other liquid gas, and successively liquefying said cooled compressed air or other gas and delivering same to said liquid charge and evaporating the same; thus continuously replenishing said liquid charge and continuously supplying dry cold evaporated liquid air or other evaporated gas to the counter-currents and the space to be cooled, substantially as set forth.

2. The art or process herein described of liquefying air or other gases and cooling thereby, which consists in subjecting a column or current of compressed air or other gas to the cooling action of a counter-current of air or gas escaping from the space to be cooled, and absorbing the moisture therefrom by the chemical action of calcium chlorid then successively subjecting said dry compressed air or other gas to the cooling action of the cold dry gas derived from a charge of liquid air or other liquid gas, in a counter-current, and to the further cooling action of said liquid charge by passing same through a conduit submerged therein, and successively liquefying said cooled dry compressed air or other gas, and delivering same to said liquid charge, and thus continuously replenishing said liquid charge and continuously supplying dry cold evaporated liquid gas from said charge to the counter-currents and space to be cooled, substantially as set forth.

3. The art or process herein described of liquefying air or other gas and cooling thereby, which consists in subjecting a column or current of compressed air or other compressed gas to the cooling action of a counter-current of air or other gas escaping from the space to be cooled; and in also subjecting the same to the drying action of a hygroscopic or moisture-absorbing substance, or bringing same in contact therewith, and thereby absorbing moisture from said compressed air or other compressed gas; and then successively subjecting said dry compressed air or other gas to the cooling action of the cold dry gas derived from a charge of liquid air or other liquid gas, in a counter-current; and to the further cooling action of said liquid charge by passing same through a conduit submerged therein, and successively liquefying said cooled dry compressed air or other gas, and delivering same to said liquid charge; and thus continuously replenishing said liquid charge and continuously supplying dry cold evaporated gas from said charge to the counter-currents and space to be cooled substantially as set forth.

707,634. VESSEL FOR HOLDING AND SHIPPING LIQUID AIR OR OTHER LIQUID GASES. JAMES F. PLAGE, Glenridge, N. J. Filed Feb. 10, 1902. Serial No. 93,239. (No model.)



Claim.—1. In a receptacle or container for liquid air or other liquefied gas, comprising an inner liquid-holding bottle or vessel and an outer case; an air-tight covering or impervious inclosure inclosing said receptacle, one part of which is infolded within itself in form of a cul-de-sac, and which serves as a lining to the inner liquid-holding bottle, and the other part or fold of which incloses a vacuum jacket or chamber around said liquid-holding bottle or vessel, substantially as shown and described.

2. In a receptacle or container for liquid air or other liquefied gas, comprising an inner liquid-holding bottle and an outer case; an inside impervious lining within said inner bottle, and an impervious covering over the outside of and inclosing said outer case—said lining and said covering being closed or soldered together so as to form an air-tight inclosure, substantially as shown and described.

3. In a receptacle or container for liquid air or other liquefied gas, comprising an inner liquid-holding bottle and an outer case; an inside impervious lining within said inner bottle, and a sack or impervious covering over the outside of and inclosing said outer case—said lining at or near the neck of same being soldered or made fast and air-tight to the mouth of said covering or sack, so as to leave the mouth or neck of said lining open, and so as to close the mouth of the outer-case covering or sack, thus forming around said outer case an air-tight inclosure, substantially as shown and described.

4. In a receptacle or container for liquid air or other liquefied gas, comprising an inner liquid-holding bottle and an outer case; the combination of an inside lining within said inner bottle, and a covering over the outside of and inclosing said outer case—said lining and said covering being impervious and closed or soldered together so as to form an air-tight inclosure; and a vacuum chamber or space between the said inside lining within said liquid-holding bottle and the said air-tight covering or inclosure around the said outer case, substantially as shown and described.

5. In a receptacle or container for liquid air or other liquefied gas, comprising an inner liquid-holding bottle and an outer case; the combination of an inside impervious lining within said inner bottle and a sack or impervious covering over the outside of and inclosing said outer case—said lining at or near the neck of same being soldered or made fast and air-tight to the mouth of said covering or sack, so as to leave the mouth or neck of said lining open, and so as to close the mouth of the outer-case covering or sack, thus forming around said outer case an air-tight inclosure; and a vacuum chamber or space between the said inside impervious lining within said liquid-holding bottle and the said air-tight covering or inclosure around the said outer case, substantially as shown and described.

6. In a receptacle or container for liquid air or other liquefied gas, the combination of an inner bottle or liquid-holder inclosed in or surrounded by an outer case; with a vacuum chamber or space between said inner bottle and said outer case; and an air-tight covering of suitable material inclosing said outer case, and infolding over the rim of the neck or mouth of and passing down into said inner bottle as an inside lining thereto, in form of a cul-de-sac, substantially as shown and described.

7. In a receptacle or container for liquid air or other liquefied gas, the combination of an inner liquid-holding bottle inclosed in or surrounded by an outer case, both said inner bottle and said outer case being made of wood or fiber or some other material of relatively low heat conductivity; with an air-tight covering or impervious inclosure which incloses said outer case, and infolds within itself or passes down into said inner liquid-holding bottle as an inside impervious lining thereto; and a vacuum chamber or space between said inclosed outer case and said inner liquid-holding bottle, substantially as shown and described.

8. In a receptacle or container for liquid air or other liquefied gas, the combination of an inner liquid-holding bottle inclosed in or surrounded by an outer case, both said inner bottle and said outer case being made of wood or fiber or other suitable material of relatively low heat conductivity; with an air-tight covering or impervious inclosure of sheet metal or other suitable material, which incloses said outer case and infolds within itself or passes down into said inner liquid-holding bottle as an inside impervious lining thereto; and a vacuum chamber or space between said inclosed outer case and said inner liquid-holding bottle, substantially as shown and described.

9. In a receptacle or container for liquid air or other liquefied gas the combination of an inner bottle or liquid-holder inclosed in or surrounded by an outer case; with a vacuum chamber or space between said inner bottle and said outer case; and an air-tight covering of suitable material inclosing said outer case, and infolding over the rim of the neck or mouth of and passing down into said inner bottle as an inside impervious lining thereto, in form of a cul-de-sac, the whole being insulated from the heat of the outside atmosphere by packings of hair felt or other material of relatively low heat conductivity, and inclosed in an outside protecting-case, substantially as shown and described.

10. In a receptacle or container for liquid air or other liquefied gas, the combination of an inner liquid-holding bottle inclosed in or surrounded by an outer case, both said inner bottle and said outer case being made of

wood or fiber or some other material of relatively low heat conductivity; with an air-tight covering or impervious inclosure which inclosure said outer case, and infolds within itself or passes down into said inner liquid-holding bottle as an inside impervious lining thereto; and a vacuum chamber or space between said inclosed outer case and said inner liquid-holding bottle, the whole being insulated from the heat of the outside atmosphere by packings of hair felt or other material of relatively low heat conductivity, and inclosed in an outside protecting-case, substantially as shown and described.

11. In a receptacle or container for liquid air or other liquefied gas, the combination of an inner liquid-holding bottle inclosed in or surrounded by an outer case, both said inner bottle and said outer case being made of wood or fiber or other suitable material of relatively low heat conductivity; with an air-tight covering or impervious inclosure of sheet metal or other suitable material, which inclosure said outer case and infolds within itself or passes down into said inner liquid-holding bottle as an inside impervious lining thereto; and a vacuum chamber or space between said inclosed outer case and said inner liquid-holding bottle, the whole being insulated from the heat of the outside atmosphere by packings of hair felt or other material of relatively low heat conductivity, and inclosed in an outside protecting-case, substantially as shown and described.

12. In a receptacle or container for solidified carbon dioxid or other solid substances which require to be insulated from the heat of the atmosphere, the combination of an inner bottle or receptacle, and an outer case; with an air-tight covering or impervious inclosure which inclosure said outer case, and infolds within itself or passes down into said inner bottle as an inside air-tight lining thereto; and a vacuum chamber or space between said air-tight-covered outer case and said air-tight-lined bottle, substantially as shown and described.

13. In a receptacle or container for solidified carbon dioxid or other solid substances which require to be insulated from the heat of the atmosphere, the combination of an inner bottle or receptacle and an outer case; with an air-tight covering or impervious inclosure which inclosure said outer case, and infolds within itself or passes down into said inner bottle as an inside air-tight lining thereto; and a vacuum chamber or space between said air-tight-covered outer case and said air-tight-lined inner bottle, and a removable receptacle adapted to slip into said air-tight-lined inner bottle, substantially as shown and described.

14. In a receptacle or container for solidified carbon dioxid or other solid substances which require to be insulated from the heat of the atmosphere the combination of an inner bottle or receptacle and an outer case; an inside impervious lining within said inner bottle, and an impervious covering over the outside of and inclosing said outer case—said lining and said covering being closed or soldered together so as to form an air-tight inclosure; and a removable substance-holding receptacle adapted to slip into said air-tight-lined inner bottle, substantially as shown and described.

15. In an insulated receptacle or container for liquid air or other liquefied gas, the combination of an inner liquid-holding bottle or vessel; with an outer receptacle inclosing said inner bottle; and an air-tight sack or covering inclosing said outer receptacle, one part of which covering is infolded within itself in form of a cul-de-sac, and which serves as an inside lining to the inner liquid-holding bottle, substantially as shown and described.

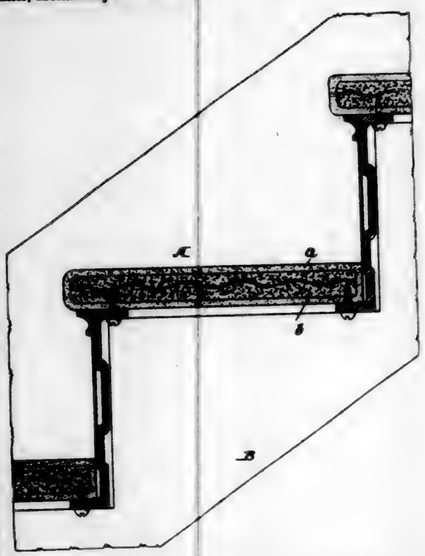
16. In a receptacle or container for insulating and preserving liquid air or other matter against the normal heat of the atmosphere, the combination of an outer receptacle inclosed by an air-tight sack or covering; with an inner bottle or vessel fixed within said outer receptacle, and having an air-tight inside lining—said covering and said lining forming one complete inclosure; and a vacuum jacket or space around said inner bottle between the lining thereof and the air-tight sack or covering of said outer receptacle, substantially as shown and described.

17. In a receptacle or container for insulating and preserving liquid air or other matter against the heat of surrounding atmosphere, the combination of an outer receptacle inclosed by an air-tight sack or covering; with an inner bottle or vessel fixed within said outer receptacle, and having an air-tight inside lining—said covering and said lining forming one complete inclosure; a vacuum jacket or space around said inner bottle, between said covering and said inside lining; and means for siphoning out or delivering from said inner bottle the liquid air or other liquefied gas therein as required, and for allowing the vapor thereof to escape, both at varying predetermined pressures, substantially as shown and described.

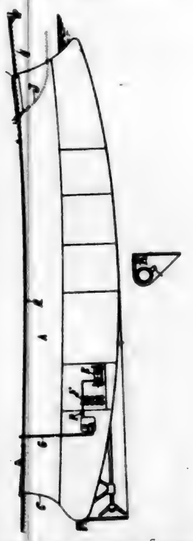
707,685. SLAB OR TILE FOR BUILDING PURPOSES. HIRAM PERLSON, Brooklyn, N. Y. Filed Jan. 10, 1902. Serial No. 89,194. (No model.)

Claim.—1. A slab or tile consisting of a core of a composition of earthy and fibrous materials, and a surface coating consisting of a composition of earthy material and finely-comminuted vegetable matter, substantially as set forth.

2. A slab or tile consisting of a core of a composition of earthy and fibrous materials, a grid embedded therein, and a surface coating consisting of a composition of earthy material and finely-comminuted vegetable matter, substantially as set forth.



707,686. OIL-SPRAYING APPARATUS. WINFIELD S. PROSSER, Ocala, Fla. Filed Jan. 21, 1901. Renewed Jan. 30, 1902. Serial No. 91,903. (No model.)



Claim.—1. In an oil-delivery system for vessels the combination of a source of supply of oil, means for regulating the pressure thereof, pipes leading from said source of supply, a series of branches connected with said pipes for delivering laterally and rearwardly over the stern of the vessel, and a second series of branches connected with said pipes for delivering forwardly and laterally over the bow of the vessel, each branch of said second series being provided with a shield arranged in front thereof.

2. In an oil-delivery system for vessels in combination with a suitable source of supply of oil and means for regulating the same, of pipes leading to the bow and stern of the vessel, the pipes leading to the stern being provided with series of vents or nipples adapted to deliver the oil downwardly, and the pipes leading to the bow being provided with series of vents or nipples adapted to deliver the oil downwardly and forwardly and with shields arranged in front of said vents or nipples, substantially as and for the purposes set forth.

3. In an oil-delivery system for vessels, the combination of a nozzle in operative connection with a receptacle for oil and provided with a series of vents or nipples adapted to deliver downwardly and forwardly, and a shield arranged in front of said nozzle, substantially as and for the purposes described.

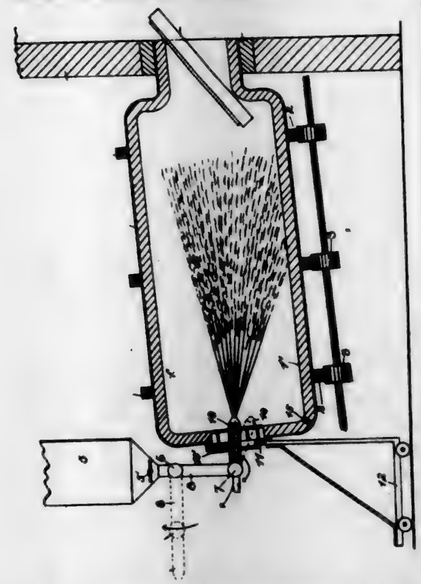
4. In an oil-delivery system for vessels, the combination of a receptacle for oil, a pipe leading therefrom toward the bow of the vessel, branches projecting from said pipe beyond the bow of the vessel, vents or nipples projecting obliquely forward from said branches, and shields situated in front of said branches, substantially as and for the purposes described.

707,687. SLIDING DOOR. GEORGE A. PROVOST and EDWIN F. CARPENTER, Janesville, Wis. Filed Oct. 14, 1901. Serial No. 78,562. (No model.)

Claim.—1. In a sliding door, a frame, L-shape hangers, tracks interlockingly connected therewith, a flange on the upper track projecting from the bearing-face, said flange having enlargements tapered from each end toward the center and an intermediate enlargement oppositely tapered to the surface of the tracks, said tapered portions forming cams for moving the door into engagement with the side of a car or into its frame, as and for the purpose described.

2. In a sliding door an upper track having a flange projecting from the bearing-face said flange having thickened portions forming cams and a lower guide having enlargements, said enlargements being tapered to form cam-surfaces which force the door inwardly, as and for the purpose described.

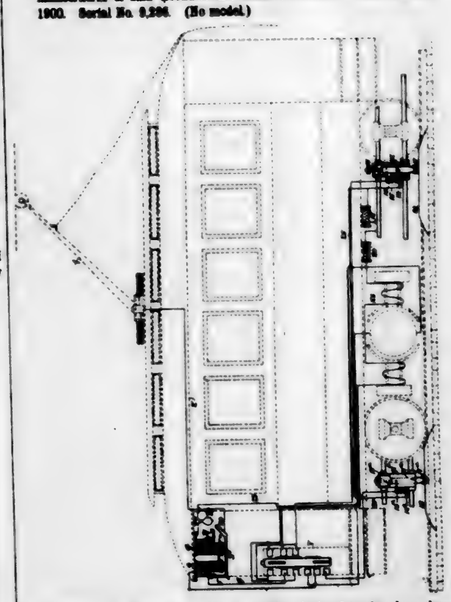
707,688. PROCESS OF PRODUCING STEEL DIRECT FROM OXID-OF-IRON ORE. DEXTER REYNOLDS, Albany, N. Y. Filed May 14, 1902. Serial No. 107,830. (No specimens.)



Claim.—1. The process of treating oxid-of-iron ores to produce therefrom wrought iron or steel, which consists, first; in mixing granulated ore with sufficient granulated carbonaceous material to deoxidize the ore and then duly carbonize the iron in it and introducing and distributing this mixture in a suitable closed furnace; second, subjecting this mixture in said closed furnace to the surface action of a neutral heating-flame until the oxid of iron is deoxidized and the iron duly carbonized; third, introducing and distributing into said furnace granulated fluxes suitable in character and amount to remove impurities; fourth, subjecting the resultant mass to the forcible direct impact of a blast-flame directed down and upon the same until the metal is fused, and fifth, separating the slag therefrom, all in one and the same furnace substantially as described.

2. The process of treating oxid-of-iron ores to produce therefrom wrought iron and steel, which consists, first; in mixing granulated ore with sufficient granulated carbonaceous material to deoxidize the ore and then duly carbonize the iron in it and introducing and distributing this mixture in a suitable furnace; second, subjecting this mixture in said furnace to the surface action of a neutral heating-flame until the oxid of iron is deoxidized and the iron duly carbonized; third, introducing and distributing into said furnace granulated fluxes suitable in character and amount to remove impurities; fourth, subjecting the resultant mass to the action of a neutral heating-flame until the metal is fused and fifth, separating the slag therefrom, all in one and the same furnace for the purposes described.

707,689. ELECTRICAL SAFETY ALARM AND SIGNAL MECHANISM FOR RAILWAYS. JOHN L. RICKETTS, Philadelphia, Pa., assignor to Leonard R. Fletcher, Philadelphia, Pa.; Eliza J. Fletcher administratrix of said Leonard R. Fletcher, deceased. Filed Mar. 19, 1900. Serial No. 9,286. (No model.)



Claim.—1. The combination in an electrical safety signal or alarm system for railways, of a normally closed car-circuit containing a magnet, a track-circuit having a contact whereby it is connected in series with the car-circuit when the engine or car reaches said contact, and means whereby such track-circuit is automatically thrown in circuit with a relatively high resistance magnet when the engine or car leaves said contact, substantially as specified.

2. The combination in an electrical safety signal or alarm system for railways, of a normally closed car-circuit containing a magnet, a track-circuit having a contact whereby it is connected in series with the car-circuit when an engine or car reaches the same, means whereby said track-circuit is automatically thrown in circuit with a relatively high resistance magnet when the engine or car passes said contact, and means whereby said track-circuit is automatically restored to its normal condition when the engine or car passes a track-contact forwardly beyond that which opened the circuit, substantially as specified.

3. The combination in an electrical safety signal or alarm system for railways, of a normally closed car-circuit containing a magnet, a number of track-circuits forming successive blocks, contacts in each of said track-circuits, and means whereby the engine or car in entering each block is caused to first connect the car-circuit in series with the track-circuit of that block and then to connect said track-circuit of said block in series with a relatively high resistance magnet, substantially as described.

4. The combination in an electrical safety signal or alarm system for railways, of a normally closed car-circuit containing a magnet, a number of track-circuits forming successive blocks, contacts in each of said track-circuits, and means whereby the engine or car in entering each block is caused to first connect the car-circuit in series with the track-circuit of that block and then to connect the track-circuit of said block in series with a high-resistance magnet, said track-circuit being connected to a contact in the block ahead of said engine or car, substantially as specified.

5. The combination in an electrical safety signal or alarm system for railways, of a car-circuit containing a magnet and a track-circuit having a contact whereby it is connected in series with the car-circuit when the engine or car reaches the same, said track-circuit including a normally closed switch provided with independent sets of pawl-and-ratchet mechanism, together with means for operating the same, each of said sets being operative upon the switch to move the same independently of each other in opposite directions, one set operating when a car-circuit is connected to the track-circuit and the other operating whenever a car-circuit is disconnected from said track-circuit, substantially as described.

6. The combination in an electrical safety signal or alarm system for railways, of a car-circuit, a track-circuit having a contact whereby it is connected in series with said car-circuit when the engine or car reaches the same, a rotary switch in said track-circuit provided with pawl-and-ratchet operating mechanism, together with a device whereby a portion of said mechanism is caused to positively move forward the switch to the extent of one tooth on each action thereof of the car-circuit of a car in a block, and means for causing the second portion of said mechanism to positively move the switch one tooth backward for each car-circuit leaving the block, substantially as described.

7. An electrically-driven car having a normally closed circuit containing a magnet which controls a switch in the motor-circuit, in combination with a track-circuit adapted to be connected in series with the car-circuit whereby the motor will be stopped when the track-circuit is open, substantially as specified.

8. An electrically-driven car having a circuit with magnet controlling a switch in the motor-circuit, said car-circuit having a switch on the trolley pole or arm, one element of said switch being a supplementary trolley adapted to strike a contact in the track-circuit and to connect said track-circuit in series with the car-circuit, substantially as specified.

9. The combination of an electrically-driven car having a circuit with magnet controlling a switch in the motor-circuit, said car-circuit having as elements a switch on the trolley-pole, a pair of contact-rings on the car, and contact-shoes carried by the rotating pole-carrier of the car, and means whereby said car-circuit can be connected in series with a track-circuit, substantially as specified.

10. An electrically-driven car having a circuit containing a magnet which controls a switch in the motor-circuit, a motor-field circuit adapted to be closed by said switch when the armature-circuit of the motor is opened, and a track-circuit adapted to be connected in series with the car-circuit, whereby, when said track-circuit is open, the motor-circuit will cause the fields of the motor to act as a magnetic brake, substantially as specified.

11. An electrically-driven car having a normally closed circuit containing a magnet which, when in one position, closes the motor-circuit, and when in the other position, closes a circuit containing a signal-lamp on the car, in combination with a track-circuit adapted to be connected in series with the car-circuit whereby, when said track-circuit is open, the motor will be stopped and the signal-lamp lighted, substantially as specified.

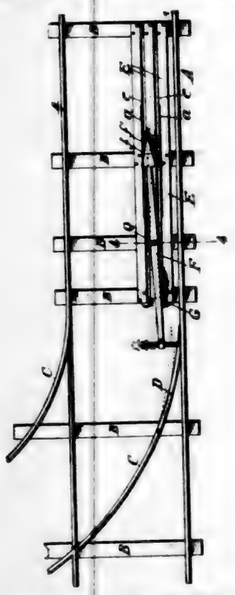
12. The combination in an electromagnetic switch, of a circuit containing a magnet with armature for opening and closing said circuit, a second circuit containing a magnet with armature for acting upon the armature of the first magnet to lock the same or restore it to circuit-closing position, a third circuit containing a magnet and adapted to be closed by the armature of the first magnet when the latter opens the circuit in which said magnet is contained, and a switch operated by said third magnet and serving to open the circuit containing the second magnet, substantially as specified.

13. The combination in an electromagnetic switch, of a rotary member consisting of a toothed circuit making and breaking device capable of being turned in opposite directions, a pair of magnets each having an armature with independent pawls adapted to act upon different sections of said toothed device whereby the action of one magnet will move it in one direction and the other in the opposite direction, two electric circuits one containing one magnet, and the other containing the other magnet, and means whereby the passage of a car is caused to close first one of these circuits and then the other, substantially as described.

14. The combination, in an electromagnetic switch, of a circuit-breaker having a disk provided with two sets of teeth with a series of teeth in each set, two magnets each having an armature with pawl, one for engaging one set of teeth and the other for engaging the other set of teeth of the circuit-breaker, two circuits, one for each magnet, and means whereby a car passing along the track is caused to open and close these circuits whereby there may be a succession of movements of the circuit-breaker in one direction caused by the action of one magnet and then a succession of movements of the circuit-breaker in the opposite direction caused by the action of the other magnet, substantially as specified.

15. The combination in an electromagnetic switch, of four electrical circuits each containing an electromagnet, a switch in the first circuit controlled by the armature of the magnet contained in said circuit, an armature operated by the magnet in the second circuit, and acting upon the armature of the magnet in the first circuit to close said circuit and hold it closed, a switch in the third circuit closed by the armature of the first magnet when the same moves so as to open the first circuit, a circuit maker and breaker operated by the magnet in the third circuit so as to open the second circuit and close the fourth circuit, and a magnet in the latter circuit for moving said circuit-breaker so as to again close the second circuit, substantially as specified.

707,640. TRAMWAY-SWITCH. ARTHUR B. ROBINSON, Dickinson, N. D. Filed Oct. 1, 1901. Serial No. 77,260. (No model.)

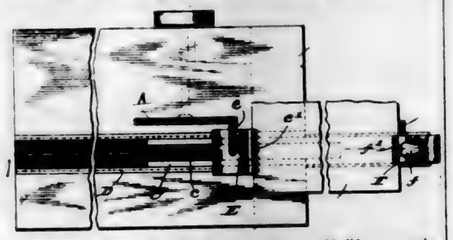


Claim.—1. The combination of the main rails, branch rails having a pivoted rail-section, straight parallel rails or plates having parallel guide-slots between them, the operating-lever having an enlarged spear-shaped head at one end arranged between the guide-slots; yielding connections between the opposite ends of said lever and the pivoted rail-section, and plates having upwardly-inclined surfaces placed between the head of the lever and the end thereof which is connected with the pivoted rail-section.

2. The combination of the main rails, the branch rails, one of which has a pivoted rail-section, a pivoted operating-lever arranged between the main rails, in position to be operated from the car, a spear-shaped head on the operating-lever, a yielding connection between the operating-lever and the pivoted rail-section, a casing attached to the car, and having a plow-shaped lower end, vertically-moving rods N, arranged in guides n' of the casing, footpieces on the upper ends of the rods, springs interposed between the footpieces and the top of the casing, a pin extending through slots in the vertically-moving rods, and a brace P attached to the lower end of the casing and the car-body, for the purpose specified.

707,641. EDGING DEVICE. JOHN ROSTOCHIL, Chicago, Ill. Filed Mar. 30, 1901. Serial No. 53,685. (No model.)

Claim.—1. A device for edging lumber, comprising a saw and saw-table, a slide arranged for forward-and-backward movement in a way extending alongside said saw, a dog or jaw mounted for sliding adjustment along the forward portion of said slide, a dog pivotally connected with the rear end of said slide and adapted to extend forward and engage the upper surface of the lumber, and an upwardly-extending handle rigid with said pivoted dog and adapted to afford a grip for moving the slide in both directions without releasing the lumber, substantially as described.



2. A saw-slide, a dog slidably mounted upon said slide, a rear pivoted dog adapted to engage the upper surface of the lumber, an upwardly-extending handle rigid with said pivoted dog, the pivot of the latter being located back of a line extending lengthwise through said handle, so that when force is exerted upon the handle for moving the slide back and forth it will be imparted downwardly to the pivoted dog and hold same in engagement with the lumber substantially as described.

3. A saw, a slide, an upright handle pivoted to the rear end of said slide, a dog slidingly mounted upon said handle and provided with means for rendering it rigid with said handle.

4. A saw, a slide, forwardly-adjustable dog, rear pivoted dog engaging the upper surface of the lumber, the pivoted dog being attached and so formed as to provide space between its engaging point or end and its pivot, so as to admit of variation in the length of lumber without necessitating readjustment of the forward dog, and an upwardly-projecting handle rigid with said pivoted dog and affording a grip for moving the slide back and forth, said handle extending in a line forward of the pivot for the jaw, so that when force is exerted upon the handle for moving the slide back and forth it will be imparted downwardly to the pivoted dog and hold same in engagement with the lumber, substantially as described.

5. In a lumber-edging device, a saw-table, a slide fitted in a way formed in the table, a jaw on the slide forming a member of the clamp, said jaw having an undercut edge facing the opposite member of the clamp and into which the ends of the boards are seated, a set-screw extending through the block and engaging the slide, a clamping-dog pivotally connected with the slide, said dog having an engaging edge formed therewith, a suitable distance forward of the pivot and a handle extending upwardly and forward of the pivot of said dog, whereby the force used in manipulating the slide can be utilized simultaneously to maintain the dog in engagement with the lumber, substantially as described.

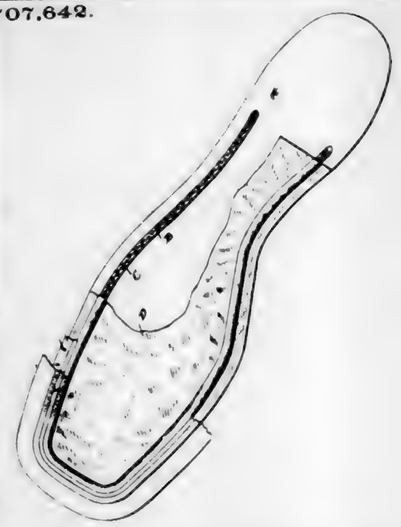
6. In a lumber-edging device, a saw-table, a slide fitted in a way formed in the table, a jaw on the slide forming a member of a clamp, said jaw comprising a block having an undercut edge facing the opposite member of the clamp and into which the ends of the boards are seated, a screw run through the block and seated in the slide, a clamping-dog having its end pivoted to the slide, said dog having an engaging member formed therewith a distance from the pivot and a handle extending upwardly and forward of the pivot whereby the force used in manipulating the slide can be utilized simultaneously to maintain the dog in engagement with the lumber, substantially as described.

707,642. INSOLE. ALBERT G. ROGERS, Buffalo, N. Y., assignor of one-half to Udo V. Schaarschuh, Buffalo, N. Y. Filed Oct. 25, 1900. Serial No. 34,332. (No model.)

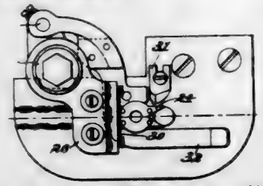
Claim.—1. The herein-described insole for shoes consisting of the body of the same thickness throughout its width, the hard abutment formed separate from the body and disposed below the same, means rigidly connecting the abutment to the body, and a cover straddling the abutment and having portions arranged adjacent to the under side of the body, whereby two thicknesses of said cover will be engaged by inseam-stitches passed between the major portion of the abutment and the under side of the body.

2. The herein-described insole for shoes consisting of the body of the same thickness throughout its width, the hard abutment of circular form in cross-section, formed separate from the body and disposed below the same, means rigidly connecting the circular abutment to the body, and a cover straddling the abutment and having portions arranged adjacent to the under side of the body, whereby two thicknesses of said cover will be engaged by inseam-stitches passed between the major portion of the abutment and the under side of the body, and spaces are formed between the circular-covered abutment and the under side of the body, substantially as and for the purpose specified.

707,642.



707,648. MACHINE FOR SETTING EYELETS. FRED A. ROBBY, East Somerville, Mass., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Jan. 22, 1901. Serial No. 44,256. (No model.)



Claim.—1. An eyeleting-machine, having, in combination, a punch acting to feed the material, a setting-die yieldingly mounted in the path of movement of the punch, a coöperating die and means for actuating the punch to feed the material and displace the setting-die, and thereafter allow said die to return to setting position between its coöperating die and the punch substantially as described.

2. An eyeleting-machine, having, in combination, a punch acting to feed the material, a setting-die located in the path of movement of the punch and movable from and to setting position, a coöperating die, means for actuating the punch to feed the material and displace the setting-die, and means for returning the die to setting position between its coöperating die and the punch substantially as described.

3. An eyeleting-machine, having, in combination, a punch acting to feed the material, a setting-die yieldingly mounted in the path of movement of the punch, a coöperating die, and means for actuating the punch to feed the material and displace the setting-die, and thereafter allow said die to return to setting position, the punch being constructed and arranged to form an abutment for said die during the setting operation, substantially as described.

4. An eyeleting-machine, having, in combination, a divided setting-die, means for holding the parts of the die in contact and means for separating said parts, substantially as described.

5. An eyeleting-machine, having, in combination, a divided annular setting-die and means for yieldingly holding the parts of the die in contact, substantially as described.

6. An eyeleting-machine, having, in combination, a divided annular setting-die, pivoted levers to which the parts of the die are secured and means acting on the levers to yieldingly hold the parts of the die in contact, substantially as described.

7. An eyeleting-machine, having, in combination, a punch acting to feed the material, a divided setting-die located in the path of movement of the punch, a coöperating die, means to hold the parts of the setting-die in contact, and means for actuating the punch to feed the material and separate the parts of the setting-die, substantially as described.

8. An eyeleting-machine, having, in combination, a punch acting to feed the material, a divided setting-die located in the path of movement of the punch, a coöperating die, means to yieldingly hold the parts of the setting-die in contact, and means for actuating the punch to feed the material and separate the parts of the setting-die, and thereafter allow said parts to come in contact, the punch being constructed and arranged to form an abutment for said die during the setting operation, substantially as described.

9. An eyeleting-machine, having, in combination, a punch, movable toward and from the work, actuating mechanism therefor, a setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch when the punch has been moved from the work, and means for relatively actuating the dies to set the eyelet, substantially as described.

10. An eyeleting-machine, having, in combination, a punch movable toward and from the work, actuating mechanism therefor, a setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch when the punch has been moved from the work, and means for relatively actuating the dies to set the eyelet, the punch being constructed and arranged to form an abutment for the setting-die during the setting operation, substantially as described.

11. An eyeleting-machine, having, in combination, a setting-die, a coöperating die, a punch acting to form a hole in and feed the material, means for actuating the punch to bring the hole formed thereby into alinement with the dies, means for moving the setting-die into a position between its coöperating die and the punch and means for actuating said coöperating die, substantially as described.

12. An eyeleting-machine, having, in combination, a setting-die, a coöperating die, a punch acting to form a hole in and feed the material, means for actuating the punch to bring the hole formed thereby into alinement with the dies, means for moving the setting-die into a positon between its coöperating die and the punch, and means for actuating said coöperating die, the punch being constructed and arranged to form an abutment for the setting-die during the setting operation, substantially as described.

13. In an eyeleting-machine, a punch and means for producing longitudinal and lateral movements thereof to punch and feed the material; a reciprocating setting device to supply eyelets and to contribute in the setting operation; and a coöperating setting device arranged to be positioned over the punched hole and supported by the punch-rod prior to the return movement thereof after the material has been punched and fed.

14. In an eyeleting-machine, a punch and means for producing longitudinal and lateral movements thereof to punch and feed the material; a reciprocating setting device to supply eyelets and to contribute in the setting operation; a coöperating setting device normally standing substantially over said first-named setting device but arranged to permit the lateral feed movement of the punch; and an engaging portion of said punch to support said coöperating setting device in the setting operation.

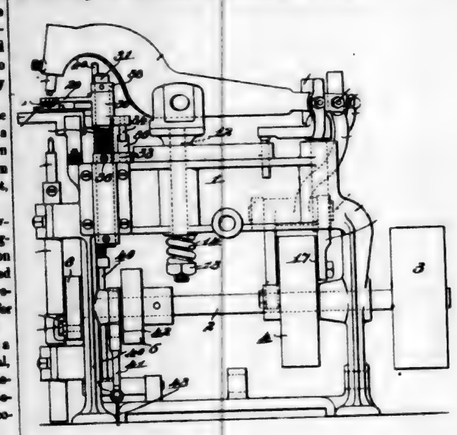
15. In an eyeleting-machine, a punch and means for producing longitudinal and lateral movements thereof to punch and feed the material; a reciprocating setting device to supply eyelets and to contribute in the setting operation; a coöperating setting device normally standing substantially over said first-named setting device; and a spring to permit a yielding movement of said coöperating setting device when engaged by the punch in the lateral or feed movement thereof and to restore the said device to operative condition when the punch rises from the material.

16. The combination with the longitudinally and laterally movable punch; of the lower set, the upper set normally standing substantially in line therewith; a spring normally holding said upper set, said spring yielding when the said upper set is engaged by the punch and restoring said upper set when the punch rises from the material; and a shoulder carried by the punch and adapted to overlie and engage a portion of the upper set when the latter is in operative position.

707,644. MACHINE FOR SETTING EYELETS. FRED A. RUMSEY, East Somerville, Mass., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Mar. 7, 1901. Serial No. 50,240. (No model.)

Claim.—1. An eyeleting-machine, having, in combination, a punch, means for actuating the punch to form a hole in the work to receive an eyelet, a setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch, means for moving the setting-die toward the work, and means for relatively actuating the dies to set the eyelet, substantially as described.

2. An eyeleting-machine, having, in combination, a punch, means for actuating the punch to form a hole in the work to receive an eyelet, a setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch, the punch being constructed and arranged to form an abutment for the setting-die, means for actuating the punch to move the setting-die toward the work, and means for actuating said coöperating die, substantially as described.



3. An eyeleting-machine, having, in combination, a punch acting to feed the work, means for actuating the punch to form a hole in the work to receive an eyelet, a setting-die movable toward and from the work yieldingly mounted in the path of movement of the punch, a coöperating die, means for actuating the punch to feed the work and displace the setting-die and thereafter allow the setting-die to move to a position between its coöperating die and the punch, the punch being constructed and arranged to form an abutment for the setting-die, means for actuating the punch to move the setting-die toward the work and means for actuating said coöperating die, substantially as described.

4. An eyeleting-machine, having, in combination, a punch acting to feed the work, means for actuating the punch to form a hole in the work to receive an eyelet, a setting-die, a coöperating die, means for actuating the punch to feed the work, means for moving the setting-die to a position between its coöperating die and the punch, the punch being constructed and arranged to form an abutment for the setting-die, means for actuating said coöperating die, substantially as described.

5. An eyeleting-machine, having, in combination, a punch, actuating mechanism therefor, an integral setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch and means for relatively actuating the dies to set the eyelet, substantially as described.

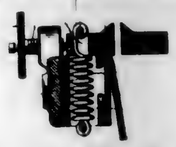
6. An eyeleting-machine, having, in combination, a punch, actuating mechanism therefor, an integral setting-die, a coöperating die, means for moving the setting-die into a position between its coöperating die and the punch, and means for actuating said coöperating die, the punch being constructed and arranged to form an abutment for the setting-die during the setting operation, substantially as described.

7. An eyeleting-machine, having, in combination, a punch acting to feed the work, means for actuating the punch to form a hole in the work to receive an eyelet, an integral setting-die yieldingly mounted in the path of movement of the punch, a coöperating die, means for actuating the punch to feed the work and displace the setting-die to one side of the punch, and thereafter allow the setting-die to move to a position between its coöperating die and the punch, the punch being constructed and arranged to form an abutment for the die during the setting operation and means for actuating said coöperating die, substantially as described.

8. An eyeleting-machine, having, in combination, a punch acting to feed the work, means for actuating the punch to form a hole in the work to receive an eyelet, an integral setting-die, a coöperating die, means for actuating the punch to feed the work, means for moving the setting-die into a position between its coöperating die and the punch, the punch being constructed and arranged to form an abutment for the setting-die, and means for actuating said coöperating die, substantially as described.

707,645. LINOTYPE-MACHINE. SAFE DEPOSIT AND TRUST COMPANY OF BALTIMORE and ABNER GREENLEAF, executors of Ottmar Mergenthaler, deceased, and WILLIAM T. HOOFNAGLE, Baltimore, Md.; said Hoofnagle assignor to the Ott. Mergenthaler Company, Baltimore, Md., a Corporation of Delaware. Filed Dec. 13, 1900. Serial No. 749,732. (No model.)

Claim.—1. In a linotype-machine, the combination of a knife-block having a seat for the trimming-knife, a slug-trimming knife movably seated on said block, a spring arranged to hold said knife firmly to its seat, and means for adjusting the knife laterally upon its seat.



2. In a linotype-machine, the combination of a knife-block, a laterally-adjustable slug-trimming knife movably seated on said block, means for adjusting the knife laterally on the block, and a spring arranged to hold the knife to its seat, said spring being connected to, and movable with, the knife.

3. In a linotype-machine, the combination of a knife-block having openings therethrough, a slug-trimming knife movably seated on said block and spanning said openings, springs extending through the openings in the knife-block and connected to the knife, and means for adjusting the knife laterally, said springs having freedom for lateral movement in the openings of the knife-block whereby they are permitted to follow the knife in its adjustment.

4. In a linotype-machine, the combination of a knife-block, a slug-trimming knife movably seated on said block, springs arranged to hold the knife to its seat, means for adjusting the knife positively in one direction, and springs arranged to hold the knife against said adjusting means.

5. In a linotype-machine, the combination of a knife-block, a slug-trimming knife movably seated on said block, adjusting-screws arranged to impart to said knife a parallel movement, and set-screws carried by the adjusting-screws for alining the knife.

6. In a linotype-machine, the combination of a knife-block, a slug-trimming knife movably seated on said block, a spring to hold said knife to its seat, a pair of adjusting-screws operating on the back of said knife, a spring to hold the knife against the adjusting-screws, pinions on said screws, a gear connecting said pinions, and a device for locking said gear in predetermined positions, for the purpose set forth.

7. In a linotype-machine, the combination with the knife-block, and the adjustable knife, of adjusting-screws for imparting to said knife a parallel movement, and the set-screws carried by and arranged axially in said adjusting-screws, for the purpose set forth.

8. In a linotype-machine, the combination of a knife-block, a slug-trimming knife movably seated on said block, adjusting-screws connected to move simultaneously, set-screws carried by said adjusting-screws and bearing on the back of the knife, springs arranged to constantly press the knife against said set-screws, and springs arranged to constantly hold the knife to its seat upon the block.

707,646. SOUP MATERIAL AND METHOD OF MAKING SAME. WALTER T. SCHEELE, Catonsville, Md., assignor of two-thirds to Hermann Knollenberg and William F. Arms, Baltimore, Md. Filed Sept. 10, 1901. Serial No. 74,977. (No specimens.)

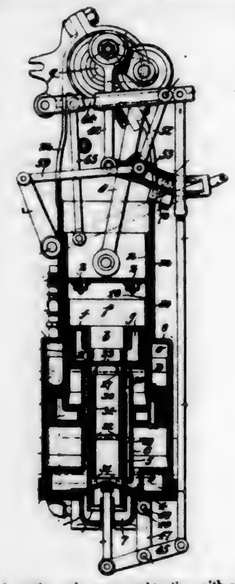
Claim.—1. The process of preparing a desiccated food product which consists in comminuting a quantity of fresh meat; mixing therewith a quantity of flour, a small quantity of yeast, and sufficient water to reduce the whole to a pasty condition; permitting the pasty mass thus prepared to stand for several hours subject to a temperature suitable to cause fermentation to take place; and finally drying the mass at a low temperature.

2. The process of preparing a desiccated food product which consists in mixing together comminuted fresh meat, flour, yeast and water substantially in the proportions of one hundred pounds of meat, one hundred and fifty pounds of flour, twenty-five ounces of yeast, and sufficient water to form a pasty mass; fermenting the mass at a temperature of about 120° for several hours; spreading the mass and drying the same at a temperature of about 140°, and finally grinding or comminuting the product thus formed.

3. The desiccated pulverized food product consisting of fermented uncooked meat and flour, the fibrin of the meat being digested and the albumen uncoagulated, substantially as described.

707,647. TELESCOPIC COMPOUND ENGINE. WILLIAM SCHEIBER, Chicago, Ill., assignor to the Whitfield Company, Memphis, Tenn., a Corporation of Mississippi. Filed Mar. 23, 1901. Serial No. 52,628. (No model.)

Claim.—1. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a valve-casing arranged axially in said cylinders, a steam-chest in communication with the live-steam inlet surrounding said casing, the latter provided with ports in communication with the steam-chest and the high and low pressure cylinder, and a valve in said casing organized to control said ports to cause the engine to work compound, for the purpose set forth.



2. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a valve-casing arranged axially in said cylinders, a steam-chest in communication with the live-steam inlet surrounding said casing, the latter provided with ports in communication with said steam-chest and the high and low pressure cylinders, and a valve movable in said casing and organized to control said ports to cause the engine to work compound or semicompound, for the purpose set forth.

3. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a valve-casing arranged axially in said cylinders, a steam-chest in communication with the live-steam inlet surrounding said casing, the latter provided with ports in communication with the steam-chest and with the high and low pressure cylinders, a valve in said valve-casing organized to control said ports and cause the engine to work either compound or semicompound and means for varying the travel of said valve to change the operation of the engine from compound to semicompound and vice versa, for the purposes set forth.

4. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment and the crank-shaft connected with the high-pressure cylinder; of a valve-casing arranged axially in said cylinders, a steam-chest, in communication with the live-steam inlet, surrounding said valve-casing, the latter provided with ports in communication with said steam-chest and with the high and low pressure cylinders, a valve in said casing organized to control said ports to cause the engine to work compound, and a reversing-gear connected with said valve for changing the direction of rotation of the engine, for the purposes set forth.

5. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, and the crank-shaft connected with said high-pressure cylinder; of a valve-casing arranged axially in said cylinders, a steam-chest, in communication with the live-steam inlet, surrounding said valve-casing, the latter provided with ports in communication with said steam-chest and with the high and low pressure cylinders, a valve in said casing organized to control said ports and cause the engine to work either compound or semicompound, a reversing-gear connected with the valve for changing the direction of rotation of the crank-shaft whether the engine works compound or semicompound, and

mechanism controlled by the reversing-gear for varying the travel of the valve and thereby changing the operation of the engine from compound to semicompound or vice versa, for the purposes set forth.

6. In a telescopic engine, the combination with the low-pressure cylinder having a chambered head connectible with a source of live-steam supply, a chambered stationary abutment, and the high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a valve-casing arranged axially in said cylinders, a steam-chest encompassing said valve-casing, said steam-chest in perpetual communication with the chambers in the low-pressure cylinder-head and stationary abutment, said valve-casing provided with suitable ports in communication with the steam-chest and with the high and low pressure cylinders, and a valve in said casing constructed to control said ports, substantially as and for the purpose set forth.

7. In a telescopic engine, the combination with the low-pressure cylinder having a chambered head connectible with a source of live-steam supply, a chambered stationary abutment, and the high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a tubular valve-casing secured to said chambered head of the low-pressure cylinder and carrying the abutment, a steam-chest encompassing the valve-casing, said steam-chest in perpetual communication with the chambers in the low-pressure cylinder-head and the abutment, said valve-casing provided with suitable ports in communication with the steam-chest and with the high and low pressure cylinders and a valve in said casing constructed to control said ports, substantially as and for the purpose set forth.

8. In a telescopic engine, the combination with the low-pressure cylinder having a chambered head connectible with a source of live-steam supply, a chambered stationary abutment, and the high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a tubular valve-casing secured to said chambered head of the low-pressure cylinder and carrying the abutment, a steam-chest encompassing the valve-casing, said steam-chest in perpetual communication with the chambers in the low-pressure cylinder-head and the abutment, said valve-casing provided with suitable ports in communication with the steam-chest and with the high and low pressure cylinders and a tubular valve closed at both ends and constructed to control said ports, substantially as and for the purpose set forth.

9. A telescopic engine, comprising a stationary cylinder provided with an extension, a crank-shaft mounted in said extension, a stationary abutment, a piston-cylinder having reciprocating motion in said stationary cylinder and on said abutment, said piston-cylinder likewise provided with an extension guided by the extension of the low-pressure cylinder, and a connection connecting the extension of the piston-cylinder with the crank-shaft, for the purpose set forth.

10. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, an air-intake in communication with the outer end of the low-pressure cylinder whereby air is drawn into said end of the low-pressure cylinder on the instroke of the high-pressure piston-cylinder, and means preventing the air from escaping through said intake on the return stroke of said high-pressure piston-cylinder; of a pipe in communication with the air-chamber in said low-pressure cylinder and with the exhaust-passage of the engine, and means for diverting the flow of air from said exhaust-passage, for the purpose set forth.

11. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, and an air-chamber in the outer end of said high-pressure piston-cylinder adapted to exhaust into the corresponding end of the low-pressure cylinder on the instroke of said high-pressure piston-cylinder, an air-intake for said air-chamber and means preventing the air therein from escaping through said intake on the outstroke of said high-pressure piston-cylinder; of a pipe in communication with the air-space in the low-pressure cylinder and with the exhaust-passage of the engine, and means for diverting the flow of air from said exhaust-passage, for the purposes set forth.

12. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, an air-intake in communication with the outer end of the low-pressure cylinder whereby air is drawn into the same on the instroke of the high-pressure piston-cylinder, and means for preventing such air from escaping through said intake on the outstroke of said high-pressure piston-cylinder, a pipe-coupling and pipes leading therefrom to the outer end of the low-pressure cylinder and to the exhaust-passage of the engine, and a branch pipe leading from said coupling; of a check-valve in the pipe leading from the coupling to the aforesaid exhaust-passage, for the purposes set forth.

13. In a telescopic engine, the combination with a low-pressure cylinder, a stationary abutment, a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, an air-intake in communication with the outer end of the low-pressure cylinder whereby air is drawn into the same on the instroke of the high-pressure piston-cylinder, and means for preventing such air from escaping through said intake on the outstroke of said high-pressure piston-cylinder, a pipe-coupling and pipes leading therefrom to the outer end of the low-pressure cylinder and to the exhaust-passage of the engine, and a branch pipe provided with a regulating-cock leading from said coupling; of a check-valve in the pipe leading from the coupling to the aforesaid exhaust-passage, for the purpose set forth.

14. A locomobile-engine comprising twin telescopic compound engines having a common exhaust-passage and comprising each a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; air-intakes in communication with the outer ends of the high and low pressure cylinders whereby air is drawn into the same on the instroke of the high-pressure piston-cylinder, and means for preventing such air from escaping through said intakes on the outstroke of said high-pressure piston-cylinder; in combination with a four-way pipe-coupling, and pipes connected thereto and in communication with the air-spaces in the high and low pressure cylinders, a third pipe connected with the said coupling and in communication with the exhaust-passage of the engines, and pressure-controlled means for diverting the flow of air from said exhaust-passage through a fourth pipe connected with said coupling, substantially as and for the purposes set forth.

15. A locomobile-engine comprising twin telescopic compound engines having a common exhaust-passage and comprising each a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment, air-intakes in communication with the outer ends of the high and low pressure cylinders whereby air is drawn into the same on the instroke of the high-pressure piston-cylinder, and means for preventing such air from escaping through said intakes on the outstroke of said high-pressure piston-cylinder; in combination with a four-way pipe-coupling, and pipes connected thereto and in communication with the air-spaces in the high and low pressure cylinders, a third pipe connected with the said coupling and in communication with the exhaust-passage of the engines, a pressure-controlled check-valve in said pipe, and a fourth pipe connected with coupling and provided with a regulating-cock, substantially as and for the purposes set forth.

16. The combination with the power cylinder and piston of a steam-engine; of an air-chamber, means for drawing air into and forcing such air from said chamber by the movements of the piston, a pipe connecting the air-chamber with the exhaust-passage of the engine, and means for diverting the flow of air from said exhaust-passage, for the purpose set forth.

17. The combination with the power cylinder and piston of a steam-engine; of an air-chamber, means for drawing air into and forcing such air from said chamber by the movements of the piston, a relief-pipe connecting the air-chamber with the exhaust-passage of the engine, a branch pipe connected with said relief-pipe, and a pressure-controlled check-valve in the last-named pipe on the exhaust side of the branch pipe, for the purposes set forth.

18. In a telescopic engine, the combination with the low-pressure cylinder, the stationary abutment and the high-pressure piston-cylinder both said cylinders closed at their outer ends; of means for preventing compression of air in the said cylinder ends, for the purposes set forth.

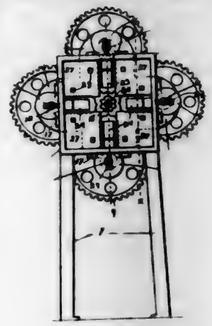
19. The combination with a telescopic engine comprising a low-pressure cylinder, a stationary abutment and a high-pressure piston-cylinder working in said low-pressure cylinder and on said abutment; of a pump-chamber, and means for drawing air into and forcing such air from said chamber by the reciprocating movements of the piston-cylinder, for the purposes set forth.

707,648. MACHINE FOR TAPERING THE ENDS OF CORRUGATED PIPES. JULIUS H. SCHLAFLY, Canton, Ohio, assignor to The Berger Manufacturing Company, Canton, Ohio. Filed Mar. 31, 1902. Serial No. 100,742. (No model.)

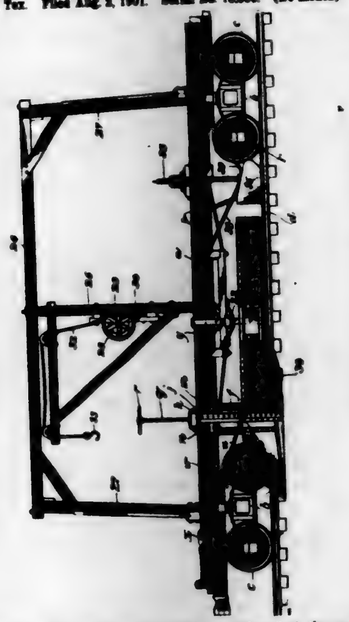
Claim.—1. In a machine of the class described, a base or support, frames carried thereby, a power-shaft provided with a pinion, cog-wheels driven from the pinion upon the power-shaft, a series of shafts located around the power-shaft, dies capable of reciprocating movement, and means for forcing the dies inward or toward each other, and a mandrel provided with a tapered portion, substantially as and for the purpose specified.

2. In a machine of the class described, a base or support, frames carried thereby, a power-shaft provided with a pinion, cog-wheels driven from the pinion upon the power-shaft, a series of shafts located around the power-shaft, dies capable of reciprocating movement, and means for imparting a reciprocating movement to the dies and a mandrel, substantially as and for the purpose specified.

707,648.



707,649. **BALLAST-SPREADING CAR.** WILLIAM R. SCOTT, Fort Worth, Tex. Filed Aug. 2, 1901. Serial No. 70,868. (No model.)



Claim.—1. In a ballast-spreader of the class described, the combination of a car provided with a set of plows arranged underneath in a horizontal plane, one at each side of the car and extending at an angle from a point outside the supporting-wheels rearwardly and inwardly to a point inside the wheels, and foldably secured to the car-frame so that they may be moved outwardly and upwardly above the car, substantially as described.

2. In a ballast-spreader of the class described, the combination of a car provided with a set of movable plows at its forward end arranged underneath the same and in a horizontal plane extending from a point outside the supporting-wheels backwardly and inwardly to a point inside the wheels and providing a space between their rear inner ends, and means for moving the plows outwardly and upwardly above the car-frame, substantially as described.

3. In a ballast-spreader of the class described, the combination of a car, a pair of plows foldably secured thereto and arranged underneath the same and extending from a point outside the supporting-wheels of the car backwardly and inwardly to a point inside the wheels and providing a space between their rear inner ends, and beams pivotally securing the plows to the car-frame so as to swing them outwardly and upwardly above the same, substantially as described.

4. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged at the forward end of such car underneath the same extending from a point outside the wheels of the supporting-car backwardly and inwardly to a point inside such supporting-wheels and providing a discharging-space between the rear inner ends of the plows, and a supplementary plow secured to the car underneath the same with its apex arranged back of and substantially in line with the center of the space between the rear ends of the forward pair of plows, substantially as described.

5. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the wheels of the supporting-car backwardly and inwardly to a point inside of such wheels, outwardly-extending beams or arms pivotally secured to the car, and upright beams on such plows secured to the pivoted swinging beams, for swinging the plows outwardly and upwardly above the car-frame, substantially as described.

6. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the wheels of the supporting-car backwardly and inwardly to a point inside of such wheels, outwardly-extending beams or arms pivotally secured to the car, and an upright beam on each of such plows adjustably secured to the swinging arms or beams, substantially as described.

7. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the wheels of the supporting-car backwardly and inwardly to a point inside of such wheels, outwardly-extending beams or arms pivotally secured to the car, an upright beam on each of such plows provided with a rectangular frame portion at the upper part thereof, and means for securing the rectangular frame portion of the plow-beam to the hinged or swinging beams, substantially as described.

8. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the supporting-wheels of the car backwardly and inwardly to a point inside of such supporting-wheels and providing a discharging-space between their rear inner ends, a pair of swinging arms or beams secured to the frame of the car, an upright plow-beam on each of such plows, means for adjustably securing such upright plow-beams to the swinging beams, and a pair of supplementary plow-beams pivotally secured to the frame of the car to assist in supporting the plows in position, substantially as described.

9. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the supporting-wheels of the car backwardly and inwardly to a point inside of such supporting-wheels and providing a discharging-space between their rear inner ends, a pair of swinging arms or beams secured to the frame of the car, an upright plow-beam on each of such plows, means for adjustably securing such upright plow-beams to the swinging beams, a pair of supplementary plow-beams pivotally secured to the frame of the car to assist in supporting the plows in position, and means for locking the supplementary plow-beams in operative position, substantially as described.

10. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the supporting-wheels of the car backwardly and inwardly to a point inside of such supporting-wheels and providing a discharging-space between their rear inner ends, a pair of swinging arms or beams secured to the frame of the car, an upright plow-beam on each of such plows, means for adjustably securing such upright plow-beams to the swinging beams, a pair of supplementary plow-beams pivotally secured to the frame of the car to assist in supporting the plows in position, a pair of outwardly-extending arms in the car-frame adapted to receive the supplementary plow-beams when in operative position, and means for locking the supplementary plow-beams in engagement with the outwardly-extending arms on the car-frame, substantially as described.

11. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the supporting-wheels of the car backwardly and inwardly to a point inside of such supporting-wheels and providing a discharging-space between their rear inner ends, a pair of swinging arms or beams secured to the frame of the car, an upright plow-beam on each of such plows, means for adjustably securing such upright plow-beams to the swinging beams, a pair of supplementary plow-beams pivotally secured to the frame of the car to assist in supporting the plows in position, a pair of outwardly-extending arms 20 on the car-frame provided with lugs 21 to receive the supplementary plow-beams between them, and a recessed plate 22 for locking the supplementary plow-beams in engagement with the outwardly-extending arms, substantially as described.

12. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same and extending from a point outside the supporting-wheels thereof backwardly

and inwardly to a point inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging arms pivotally secured to the car-frame and extending outwardly from each side thereof, plow-beams secured to such swinging arms, by which the plows are swung outwardly and upwardly above the car-frame, a pair of chains—one secured to each plow-beam, and a rotatable drum on which such chains are wound to tighten and loosen the same and hold the plows in proper operative position, substantially as described.

13. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged at or near the front portion thereof and extending from points at each side of the car outside of the supporting-wheels thereof backwardly and inwardly underneath the car to a point inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the car-frame and extending out from each side thereof, a plow-beam for each plow adjustably secured to its proper swinging beam, a pair of chains—one for each plow-beam, a drum upon which each chains are wound, a vertically-arranged shaft operating each drum, and pawl-and-ratchet mechanism for holding the shaft against rotation at the proper time or times, substantially as described.

14. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, and a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow-beam to its respective swinging beam, substantially as described.

15. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow-beam to its respective swinging beam, two-part stay-rods hinged together and pivotally secured to the forward end of the car extending backwardly and outwardly and pivotally secured to each plow, respectively, substantially as described.

16. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow-beam to its respective swinging beam, and a two-part stay-rod hinged together and provided with a turnbuckle for each plow pivotally secured thereto and to the car-frame, substantially as described.

17. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow to its respective swinging beam, two-part stay-rods hinged together and pivotally secured to the forward end of the car extending backwardly and outwardly and pivotally secured to each plow, respectively, supplementary plow-beams adjustably secured to each plow and pivotally secured to the car-frame, and means for locking such supplementary plow-beams at their downward limit of motion and operative position, substantially as described.

18. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow-beam frame to its respective swinging beam, two-part stay-rods hinged together and pivotally secured to the forward end of the car extending backwardly and outwardly and pivotally secured to each plow, respectively, supplementary plow-beams adjustably secured to each plow and pivotally secured to the car-frame, means for locking such supplementary plow-beams at their downward limit of motion and operative position, a supplementary plow in the rear of the first-named plows having its apex substantially in line with the central portion of the discharging-space between such plows and underneath the car, and a post on which such supplementary plow is mounted extending up through the car, and spring mechanism for holding such post at its downward limit of motion, substantially as described.

19. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels backwardly and inwardly to points inside of such wheels and providing a discharging-space between their rear inner ends, a pair of swinging beams pivotally secured to the frame of the car and extending outwardly from each side thereof, a plow-beam for each plow provided with rectangular frame portions at their upper ends, a U-shaped bolt for each swinging beam provided with nut mechanism and adjustably securing each plow-beam frame to its respective swinging beam, two-part stay-rods hinged together and pivotally secured to the forward end of the car extending backwardly and outwardly and pivotally secured to each plow, respectively, supplementary plow-beams adjustably secured to each plow and pivotally secured to the car-frame, means for locking such supplementary plow-beams at their downward limit of motion and operative position, a supplementary plow in the rear of the first-named plows having its apex substantially in line with the central portion of the discharging-space between such plows and underneath the car, a post on which such supplementary plow is mounted extending up through the car, spring mechanism for holding such post at its downward limit of motion, and crane mechanism pivotally mounted on each car and provided with the usual winding-drum, rope and hook for raising and lowering the plows out of and into position, substantially as described.

20. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels of the car backwardly and inwardly to points inside of such wheels, means for foldably securing such plows to the car, whereby they may be moved upwardly and inwardly to be carried thereby, chain and stay-rod mechanism to assist such plows in resisting the strains incident to work, a supplementary plow arranged underneath the car in the rear of the forward pair of plows to complete the spreading of the ballast, a vertically-arranged post upon which such supplementary plow is mounted movably mounted in the platform of the car and extending up therefrom, spring mechanism for holding such post and its plow at the downward limit of motion, stay-rod mechanism for such plow to assist it in resisting the strains incident to use, and a clip or similar element secured to the movable post by which the post and plow may be raised out of operative position, substantially as described.

21. In a ballast-spreader of the class described, the combination of a supporting-car, a pair of plows arranged underneath the same at the forward end thereof extending from points outside the supporting-wheels of the car backwardly and inwardly to points inside of such wheels, means for foldably securing such plows to the car, whereby they may be moved upwardly and inwardly to be carried thereby, chain and stay-rod mechanism to assist such plows in resisting the strains incident to work, a supplementary plow arranged underneath the car in the rear of the forward pair of plows to complete the spreading of the ballast, a vertically-arranged post upon which such supplementary plow is mounted movably mounted in the platform of the car and extending up therefrom, spring mechanism for holding such post and its plow at the downward limit of motion, stay-rod mechanism for such plow to assist it in resisting the strains incident to use, a clip or similar element secured to the movable post by which the post and plow may be raised out of operative position, a longitudinally-arranged beam above the platform of the car and supported at or near each end of such car, and a crane having its vertical post pivotally mounted in the platform of the car and in the longitudinal beam to raise and lower the plow mechanisms out of and into operative position, substantially as described.

707,650. ANTIFRICTIONAL BEARING. FREDERIC S. SEAGRAVE and HOMER P. ELLIOTT, Columbus, Ohio; said Elliott assignor to said Seagrave. Filed Nov. 29, 1899. Serial No. 737,849. (No model.)

Claim.—The combination with a spindle having peripheral groove, of a ring formed of semicircular sections hinged at their adjacent ends and having a flange portion engaged in said groove and portions embracing the periphery of the spindle, a recessed ring bearing against one side of the sectional ring, a ring bearing against the shoulder of the spindle, and rollers having projecting end pins seated in channels in the last-mentioned rings, an inclosing boxing, and thrust-bearings, all substantially as shown and described.

707,651. FLUID-PRESSURE REGULATOR. ROBERT W. SETZE and FRANK PRATT, Indianapolis, Ind. Filed Nov. 27, 1901. Serial No. 83,826. (No model.)

Claim.—1. A fluid-pressure regulator including a hollow case having a chamber and opposing stop members, a main valve having a valve-seat therein and a passage-way therethrough and operating between the opposing stop members, and a secondary valve mounted in the main valve below the seat therein.

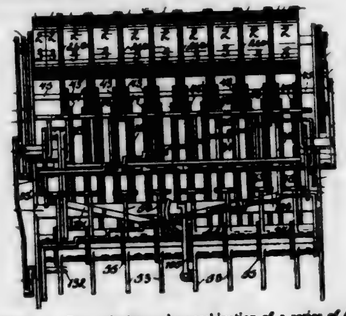
2. A fluid-pressure regulator including a hollow case, a main valve in the case composed of flexible material having a passage-way therethrough and a valve-seat, a secondary valve mounted in the main valve opposite the valve-seat, and stop members limiting the movements of the valves.

3. A fluid-pressure regulator including a case, a flanged main valve mounted in the case and adapted to permit the passage of fluid under low pressure and to be actuated by increased pressure, a stop member in the path of the valve-flange adapted to be engaged thereby whereby the flow of fluid may be limited, a passage-way through the main valve, and a secondary valve mounted in the main valve opposite the inlet-orifice of the passage-way.

4. In a fluid-pressure regulator, the combination of the case having the internal annular stop member, the opposing stop member, a main valve seated against the annular stop member and adapted to be moved against the opposing stop member, a passage-way through the main valve, a secondary valve carried by the main valve opposite the inlet-orifice of the passage-way, a stem attached to the secondary valve and extending through the passage-way, a stop member attached to the stem, and a duct extending from the passage-way to the exterior of the main valve.

5. In a fluid-pressure regulator, the combination of the hollow case, the main valve having the valve-chamber in the lower part thereof and the smaller chamber above the valve-chamber, the annular external flange on said valve, the passage-way through said valve, the secondary valve mounted in said valve-chamber, the valve-stem, the stop member on said stem, and the stop members limiting the movements of said main valve whereby when engaged by said flange the flow of the fluid through the case shall be limited.

707,652. CALCULATOR. EDWARD W. SIBLEY, Providence, R. I., assignor of two-thirds to Henry Dunster, Jr., and Horace Thurston, Providence, R. I. Filed July 3, 1901. Serial No. 67,005. (No model.)



Claim.—1. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls thereon; each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of any of said keys to move the pawl-carrying shaft and thereby so move an indicator that the latter registers the digit of the operating-key; and means for bringing any desired pawl into position of engagement with its ratchet-wheel to operate the connected indicator.

2. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon; each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; a rotatable sleeve connected with said shaft and arranged to rock the pawls in succession; means for rotating the sleeve and thereby bring any desired pawl into position of engagement with its ratchet-wheel to operate the connected indicator; and means for causing the operation of any of said keys to move the pawl-carrying shaft and thereby operate an indicator so that the latter registers the digit of the operating-key.

3. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls, each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; a rotatable sleeve connected with said shaft and arranged to engage the pawls; said sleeve have a helical series of notches each located at a pawl-engaging portion of the sleeve; means for rotating the sleeve, and thereby bring any of the notches into engagement with its pawl and place the latter in position to operate the connected indicator; and means for causing the operation of any of the said keys to move an indicator so that the latter registers the digit of the operated key.

4. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon, each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; a rotatable sleeve connected with the shaft and arranged to rock the pawls in succession; a second set of keys; means for causing the operation of each latter key to rotate the sleeve and thereby bring a pawl into position of engagement to operate the indicator corresponding to the latter key operated; and means for causing the operation of any of the said digit-keys to move the pawl-carrying shaft and thereby move an indicator so that the latter registers the digit of the operated key.

5. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven

from one of the ratchet-wheels; a shaft having a series of pawls thereon each pawl being disposed in alinement with one of said ratchet-wheels means for bringing any desired pawl into engagement with its ratchet-wheel; a pair of levers; means for causing the levers to rock said pawl-carrying shaft; a step-bar connecting said levers; a set of movable digit key-bars; means for retaining the key-bars normally in alinement; the key-bars being so disposed as to engage respectively the steps of the step-bar and thereby rock said levers.

6. In a calculator, the combination of a series of digit-indicators; separate means for moving each of the indicators and cause it to register any digit; a pair of levers; a step-bar connecting said levers; a set of key-bars, each having a gear thereon; means for retaining the key-bars normally in alinement; a rock-bar located opposite each key-bar and having a gear thereon; the said gear on each key-bar engaging the gear on the opposite rock-bar; said step-bar being located between the set of key-bars and the set of rock-bars, with the steps disposed to be each engaged by a key-bar and its opposite rock-bar; a set of digit-keys; one of said levers being arranged to cause any one of said indicator-moving means to be operated by any of said digit-keys when operated, and thereby register the digit of the operated key.

7. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls thereon, each pawl being disposed in alinement with one of said ratchet-wheels; a rotatable sleeve connected with said shaft and arranged to rock the pawls in succession; a gear on said sleeve; a pair of levers; means for causing one of said levers to rotate said gear; a step-bar connecting said levers; a set of key-bars, each having a gear thereon; means for retaining the key-bars normally in alinement; a rock-bar located opposite each key-bar and having a gear thereon; the said gear on each key-bar engaging the gear on the opposite rock-bar; said step-bar being located between the set of key-bars and the set of rock-bars with the steps disposed to be each engaged by a key-bar and its opposite rock-bar; a set of digit-keys; and means for causing the operation of any of said latter keys to move the pawl-carrying shaft and thereby operate an indicator so that the latter registers the digits of the operating-key.

8. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a pair of pivoted arms; a shaft carried by the free extremity of said arms; a series of pawls mounted on said shaft; each pawl being disposed in alinement with one of said ratchet-wheels; a rotatable sleeve mounted on said shaft; means on the sleeve for rocking said pawls in succession upon the rotation of the sleeve; a set of digit-keys; means for causing the depression of any of said keys to rock said arms and thereby cause a pawl to move a ratchet-wheel and operate an indicator; and means for causing the return movement of said arms and pawls upon the release of a depressed key, to rotate said sleeve and thereby move the pawl just operated away from its engaging ratchet-wheel, and also move the adjacent pawl into position to engage its ratchet-wheel.

9. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a pair of pivoted arms; a shaft carried by the free extremity of said arms; a series of pawls mounted on said shaft; each pawl being disposed in alinement with one of said ratchet-wheels; a rotatable sleeve mounted on said shaft and arranged to bring successive pawls into position of engagement; a pivoted lever having a pawl mounted thereon; a ratchet-wheel arranged to engage said pawl; a gear mounted on said sleeve; a pin-wheel connected with said ratchet-wheel and normally in engagement with said sleeve-gear; a second pivoted lever having a notched portion arranged to engage one extremity of said lever; the first-mentioned lever being arranged to bring its extremity into engagement with the notched portion of the second lever; the second lever having its extremity disposed so as to be moved by one of said arms on the return movement of the latter after having operated one of its supporting-pawls, and thereby cause the first lever to be tripped from said notch; means for moving the first lever in a reverse direction; said pawl and ratchet-wheel being so arranged that on the said reverse movement of said first lever the pawl engages and moves its ratchet-wheel, and thereby rotates the sleeve to bring an adjacent pawl into position of engagement; a set of digit-keys; and means for causing the depression of any of said keys to rock said arms and connected pawl and operate an indicator.

10. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a set of digit-keys; means for causing the depression of any of said keys to rock said arms and pawls and cause a ratchet-wheel to move an indicator; a pair of pivoted arms; a shaft carried by the free extremity of said arms; a series of pawls mounted on said shaft, each pawl being disposed in alinement with one of said ratchet-wheels; a rotatable sleeve mounted on said shaft; and arranged to bring successive pawls into position of engagement; a pivoted lever having a pawl mounted thereon; a ratchet-wheel arranged to engage said pawl; a gear mounted on said sleeve; a pin-wheel connected with said ratchet-wheel, and normally in engagement with said sleeve-gear; a second pivoted lever having a notched portion arranged to engage one extremity of said lever; the first-mentioned lever being arranged to bring its extremity into engagement with the notched portion of the second lever; the second lever having its extremity disposed so as to be moved by one of said arms on the return movement of the latter after having operated one of its supporting-pawls and thereby cause the first lever to be tripped from said notch; means for moving the first lever in a reverse direction; said pawl and ratchet-wheel being so arranged that on the said reverse movement of said first lever the pawl engages and moves its ratchet-wheel, and thereby rotates the sleeve to bring an adjacent pawl into position of engagement; means for causing the operation of any of said keys to rock said first lever and thereby cause the sleeve to bring an adjacent pawl into position of engagement.

11. In a calculator, the combination of a shaft; a series of sleeves loosely mounted on said shaft and secured together; a series of digit-cylinders each having a disk portion; means for causing the digit-cylinders to register any desired digit; each disk being loosely mounted on one of said sleeves; a second disk secured to each of said sleeves and having a notch in its periphery; a ratchet-wheel secured to said second disk, a pawl pivoted on the first disk and arranged to engage said second disk on an adjacent cylinder at its notched portion, and to also engage the adjacent ratchet-wheel; a gear on each of said cylinders; means for rotating each of said cylinders; said disk being arranged to normally hold the pawl from engaging the adjacent ratchet-wheel; said disk having its notch arranged to permit the pawl when traveling in a certain direction to engage a tooth when rotated and thereby move the ratchet-wheel and attached cylinder for one-tenth of a revolution, and thereupon force the pawl from engagement with the ratchet-wheel; said disk having its notch also arranged to engage the pawl when the latter is moving in the same direction and be carried around with it.

12. In a calculator, the combination of a shaft; a series of sleeves loosely mounted on said shaft and secured together; a series of digit-cylinders each having a disk portion; means for causing the cylinders to register any desired digit; each disk being loosely mounted on said sleeves; a second disk secured to each of said sleeves and having a notch in its periphery; a ratchet-wheel secured to said first disk; a pawl pivoted on the first disk and arranged to engage said second disk on an adjacent cylinder at its notched portion and to also engage the adjacent ratchet-wheel; a gear on each of said cylinders; means for rotating each of said cylinders; said disk being arranged to normally hold the pawl from engaging the adjacent ratchet-wheel; said second disk having its notch arranged to permit the pawl when traveling in a certain direction to engage a tooth when rotated, and thereby move the ratchet-wheel and attached cylinder for one-tenth of a revolution, and thereupon force the pawl from engagement with the ratchet-wheel; said second disk having its notch also arranged to engage the pawl when the latter is moving in a certain direction and be carried around with it; a gear secured to said sleeve; and a pivoted key-bar having a segment-gear arranged to engage said gear and rotate it one revolution on the depression of the key-bar, and thereby cause the said sleeve and disks to engage with the registering-cylinders and move them through the balance of a revolution.

13. In a calculator, the combination of a series of digit-indicators; a set of ratchet wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a pair of pivoted arms; a shaft carried by the free extremities of said arms; a series of pawls mounted on said shaft, each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the depression of any of said keys to bring a pawl to move a ratchet-wheel and thereby move an indicator; means for returning all of said indicators to "0;" and means for causing said latter operation to throw all of the pawls out of engagement with the ratchet-wheels.

14. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls thereon; each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; a rotatable sleeve connected with said shaft and arranged to rock the pawls in succession; means for causing the operation of any of the keys to move the pawl-carrying shaft and thereby move an indicator so that the latter registers the digit of the operating-key; means for rotating the sleeve and thereby bring any desired pawl into position of engagement with its ratchet-wheel to operate the connected indicator; means for returning all said indicators to "0;" and means for causing said latter operation to move said sleeve and thereby throw all the pawls out of position of engagement with their ratchet-wheels.

15. In a calculator, the combination of a set of indicators, a second set of indicators; a plurality of digit-keys; means for causing the operation of said keys to register a certain number on the first set of indicators; means for causing the operation of said keys to register a certain number on the second set of indicators; a third set of indicators; and means for causing the operation of the keys that caused those two numbers to be registered to automatically register the product of the two said numbers on the third set of indicators.

16. In a calculator, the combination of a set of indicators; a second set of indicators; a plurality of digit-keys; means for causing the operation of said keys to register a certain number on the first set of indicators; means for causing the operation of said keys to register a certain number on the second set of indicators; a third set of indicators; and means for causing the operation of the keys that caused those two numbers to be registered to automatically register the product of the two said numbers on the third set of indicators; means for setting the second set of indicators at "0;" and means for causing the set of again setting up a number on the second set of indicators, when reset, without disturbing the other registered number or the said product, to cause the product of the said number registered on the first set of indicators by the number last registered on the second set of indicators, to be automatically added to the said product, thereby registering the sum of the two products on the third set of indicators.

17. In a calculator, the combination of a set of digit-indicators; means for causing any of the indicators to register any digit; a second set of digit-indicators; means for causing any of the latter indicators to register any digit; a third set of digit-indicators; and means for causing the operation of registering a digit on the second set of indicators, when a digit has been registered on any of the first set of indicators, to automatically move one of the indicators in the third set through a number of its digit-spaces equal to the product of the number of digit-spaces through which the first said indicator moved to register the said number, multiplied by the number of digit-spaces through which the second indicator moved to register the second number.

18. In a calculator, the combination of a set of digit-indicators; means for causing any of the indicators to register any digit; a second set of indicators; a third set of indicators; means for causing any of the second set of indicators to register any digit; and means for causing the movement of one of said second indicators through each of its digit-spaces, when a digit has been registered on the first set of the indicators, to automatically move one of the third set of indicators through a number of digit-spaces equal to the digit that was caused to register on a digit-indicator of the first set.

19. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register any digit; a second set of indicators; a third set of indicators; means for causing any of the second set of indicators to register any digit; and means for causing the movement of any one of the second indicators through each of its digit-spaces, when a number has been registered on the first set of indicators, to automatically move a plurality of adjacent indicators in the third set, equal in number to the digits of said number, each through a number of digit-spaces equal respectively to the digit corresponding in order in the said number.

20. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register a given number; a second set of digit-indicators; a third set of digit-indicators; means for causing the second set of indicators to register a given number; means for causing the act of registering the left-hand digit of a number, on the second set of indicators, when a number has been registered on the first set of indicators, to automatically register on the third set of indicators, the product of the first number by a number composed of the said left-hand digit with the remaining digits of the number replaced by naughts.

21. In a calculator, the combination of a set of indicators; a second set of indicators; a plurality of digit-keys; means for causing the operation of said keys to register a certain number on the first set of indicators; means for causing the operation of the said keys to register a certain number on the second set of indicators; a third set of indicators; means for causing the operation of the keys that caused those two numbers to be registered, to automatically register the product of the said two numbers of the third set of indicators; means for setting the second set of indicators at "0;" and means for causing the act of again setting up a number on the second set of indicators when reset, without disturbing the other said number, or the said product, to cause the product of the said number on the first set of indicators by the number last caused to register on the second set of indicators, to be automatically added to the said product, thereby registering the sum of the two products on the third set of indicators; said latter means being arranged to the operation of resetting and registering of subsequent numbers on the second set of indicators to multiply the first number by these numbers and add the product in each instance to the aggregate on the preceding products.

22. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register a given number; a second set of digit-indicators; a third set of digit-indicators; means for causing the second set of indicators to register a given number; operating means for causing the act of registering the left-hand digit on the second set of indicators, when a number has been registered on the first set of indicators, to automatically register on the third set of indicators the product of the said first number by a number composed of the said left-hand digit with the remaining digits of the number replaced by naughts; said operating means being also arranged to cause the registering of the next digit of the said number to multiply the first number by a number composed of the latter digit with the remaining digits to the right in the said number replaced by naughts, and adding this latter product to the said product, causing their sum to replace the said product on the third set of indicators; and means for causing the registering of the remaining digits of the second number to likewise multiply the first number by the digit with as many naughts as there are remaining digits to the right in the number, and adding their products to the aggregate of the preceding products, thereby causing the product of the first number by the second number to be registered on the third set of indicators.

23. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls slidable thereon but rotatable therewith; each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of any of said keys to move the pawl-carrying shaft and thereby so move an indicator that the latter registers the digit of the operating-key; and means for bringing any desired pawl into position of engagement with its ratchet-wheel to operate the connected indicator; a second series of digit-indicators; a second set of ratchet-wheels; means for causing each of the latter indicators to be driven from one of said latter ratchet-wheels; and means for bringing said pawls into position to operate either of said sets of ratchet-wheels.

24. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of the ratchet-wheels; a shaft having a series of pawls slidable thereon but rotatable therewith; each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of any of said keys to move the pawl-carrying shaft and thereby so move an indicator that the latter registers the digit of the operating-key; and means for bringing any desired pawl into position of engagement with its ratchet-wheel to operate the connected indicator; a second series of digit-indicators; a second set of ratchet-wheels; means for causing each of the latter indicators to be driven from one of said latter ratchet-wheels; and means for sliding said pawls on said shaft to bring them opposite either of said sets of indicators.

25. In a calculator, the combination of a series of digit-indicators; a set of ratchet-wheels; means for causing each of the indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon, each pawl being disposed in alinement with one of said ratchet-wheels; a set of digit-keys; a rotatable sleeve connected with said shaft and arranged to engage the pawls; means on the sleeve for rocking the pawls in succession; a second set of keys, one for each of the indicators; means for causing the operation of each latter key to rotate the sleeve and thereby bring a pawl into position of engagement to operate the indicator corresponding to the latter key operated; means for causing the operation of any of the said digit-keys to move the pawl-carrying shaft and thereby move an indicator so that the latter registers the digit of the operating-key; and means for reciprocating said pawls and sleeves to bring them opposite either set of ratchet-wheels.

26. In a calculator, the combination of a series of digit-indicators; means for causing the indicators to register; means for returning the indicators to "0;" a second set of digit-indicators; means for causing the latter indicators to register; means for returning the second set of indicators to "0;" and means for causing said latter means to operate said former returning means.

27. In a calculator, the combination of a set of digit-keys; a series of digit-indicators; means for causing the operation of each of the keys to actuate any of the indicators and thereby register the digit of the operating-key; and means actuated on the operation of a said key for causing the succeeding operation of a said key to move an indicator adjacent the indicator last operated and thereby register the digit of the latter key; the series of indicators being divided into two sets; means for returning one set of indicators to "0" without disturbing the other set of indicators; and means for causing the said latter operation to cause the succeeding operation of any of said keys to register its digit on an indicator of the set returned to "0."

28. In a calculator, the combination of a shaft; a series of sleeves loosely mounted on the shaft and secured together; a ratchet-wheel on each sleeve; a series of digit-cylinders each having a ratchet-wheel secured thereto and also having a notched disk; a gear mounted loosely on

each of said sleeves and located between each of said cylinders; a pawl on each of said gears, and arranged to engage the ratchet-wheel of a cylinder and to also engage the ratchet-wheel of an adjacent sleeve; a pawl on each of the sleeve ratchet-wheels and arranged to engage said notched disks; said first-mentioned pawl being arranged to rotate an adjacent cylinder on the operation of its supporting-gear and to also rotate the series of sleeves; said pawls on the sleeve-disk being arranged to each engage the notch on its adjacent disk on the rotation of said sleeves and thereby bring all of the cylinders to "0."

29. In a calculator, the combination of a series of digit-indicators; means for causing any of the indicators to register any digit; a wheel connected with said indicators; and means for causing the rotation of each of the indicators to rotate said wheel for a distance proportional to the number of digit-spaces through which the indicator moves.

30. In a calculator, the combination of a series of digit-indicators; means for causing any of the indicators to register any digit; a wheel connected with said indicators; means for causing the registering of any of the indicators to rotate said wheel for a distance proportional to the number of digit-spaces through which the indicator moved; and means for causing the rotation of said wheel in a direction the reverse of that in which it was moved by the indicators, to bring all of said indicators to the position of "0."

31. In a calculator, the combination of a set of digit-indicators; a second set of digit-indicators; a third set of digit-indicators; a set of ratchet-wheels; means for causing any of the first and second set of digit-indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon; each pawl being in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of each of the keys to move the pawl-carrying shaft a distance proportional to the digit of the operating-key; means for bringing any desired pawl into position of engagement with its ratchet-wheel; a second shaft; a series of gears mounted on said second shaft and each arranged to operate an indicator of the third set; a ratchet-wheel connected with each of said gears; a lever loosely mounted on said second shaft adjacent to each of said gears; a pawl pivoted on each of said levers and arranged to engage one of the latter ratchet-wheels; an extension on each latter pawl; a third shaft; a sleeve arranged to slide on the third shaft but rotated thereby; a carriage arranged to move said sleeve axially when reciprocated; a series of arms on said sleeve each arranged to engage and move one of said levers on the rotation of the sleeve and thereby cause the pawls on these levers to rotate their ratchet-wheels and move the third set of indicators; a series of movable shields mounted on said carriage and arranged to engage the extensions of said pawls respectively and normally hold these pawls out of engagement; the pawls that operate the first set of indicators each having an arm thereon arranged to engage one of said shields and move it a certain distance to permit a lever-carried pawl to engage its ratchet-wheel, and when moved by a said arm move an indicator a number of spaces equal to the digit of the key depressed to operate a pawl of the first set; and means for causing the operation of any of the second set of indicators to rotate said third shaft and cause said arm-carrying sleeve to rotate and thereby rock the pawl-carrying arms once for each movement of the latter indicator through one space.

32. In a calculator, the combination of a set of digit-indicators; a second set of digit-indicators; a third set of digit-indicators; a set of ratchet-wheels; means for causing any of the first and second set of digit-indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon, each pawl being in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of each of the keys to move the pawl-carrying shaft a distance proportional to the digit of the operating-key; means for bringing any desired pawl into position of engagement with its ratchet-wheel; a second shaft; a series of gears mounted on said second shaft and each arranged to operate an indicator of the third set; a ratchet-wheel connected with each of said gears; a lever loosely mounted on said second shaft adjacent to each of said gears; a pawl pivoted on each of said levers and arranged to engage one of said latter ratchet-wheels; an extension on each latter pawl; a third shaft; a sleeve arranged to slide on the third shaft but rotated thereby; a carriage arranged to move said sleeve axially when reciprocated; a series of arms on said sleeve each arranged to move one of said levers on the rotation of the sleeve and thereby cause these levers to rotate their ratchet-wheels and move the third set of indicators; a series of movable shields mounted on said carriage and arranged to engage the extensions of said pawls respectively and normally hold these pawls out of engagement; the pawls that operate the first set of indicators each having an arm thereon arranged to engage one of said shields and move it a certain distance to permit a lever-carried pawl to engage its ratchet-wheel, and when moved by said latter arm to move an indicator a number of spaces equal to the digit of the key depressed to operate a pawl of the first set of indicators; means for causing the operation of any of the second set of indicators to rotate said third shaft and cause said arm-carrying sleeve to rotate and thereby rock the pawl-carrying arms once for each movement of the latter indicator through one space; and means for causing the act of registering a number on certain of the indicators of the first and second sets to move the carriage into position of coöperation with other of the said gears.

33. In a calculator, the combination of a set of digit-indicators; a second set of digit-indicators; a third set of digit-indicators; a set of ratchet-wheels; means for causing any of the first and second sets of digit-indicators to be driven from one of said ratchet-wheels; a shaft having a series of pawls thereon; each pawl being in alinement with one of said ratchet-wheels; a set of digit-keys; means for causing the operation of each of the keys to move the pawl-carrying shaft a distance proportional to the digit of the operating-key; means for bringing any desired pawl into position of engagement with its ratchet-wheel; a series of gears mounted on said second shaft and each arranged to operate an indicator of the third set; a ratchet-wheel connected with each of said gears; a lever loosely mounted on said second shaft adjacent to each of said gears; a pawl pivoted on each of said levers and arranged to engage one of said latter ratchet-wheels; an extension on each latter pawl; a third shaft; a sleeve arranged to slide on the third shaft but rotated thereby; a carriage arranged to move said sleeve axially when reciprocated; a series of arms on said sleeve each arranged to move one of said levers on the rotation of the sleeve and thereby cause these levers to rotate their ratchet-wheels and move the third set of indicators; a series of movable shields mounted on said carriage and arranged to engage the extensions of said pawls respectively and normally hold these pawls out of engagement; the pawls that operate the first set of indicators each having an arm thereon arranged to engage one of said shields and move it a certain distance to permit a lever-carried pawl to engage its ratchet-wheel, and when moved by said latter arm to move an indicator a number of spaces equal to the digit of the key depressed to operate a pawl of the first set of indicators; means for causing the operation of any of the second set of indicators to rotate said third shaft and cause said arm-carrying sleeve to rotate and thereby rock the pawl-carrying arms once for each movement of the latter indicator through one space; a carriage for said sleeve; means for causing the movement of said carriage; a series of curved guides mounted on the carriage in transverse alinement; a curved shield slidable on each guide and arranged to reciprocate; means for holding each shield at one limit of its movement; a pawl on each shield; and a pivoted rack-bar arranged to engage with each said pawl and retain the shield in the positions to which moved from said limit of movement.

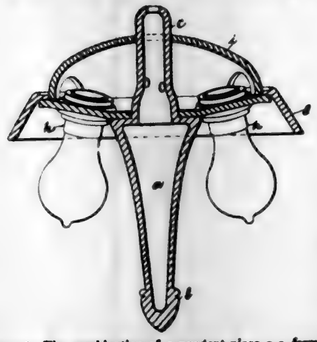
34. In a calculator, the combination of a carriage; a series of curved guides mounted on the carriage in transverse alinement; a curved shield slidable on each guide and arranged to reciprocate; means for holding each shield at one limit of its movement; a pawl on each shield; and a pivoted rack-bar arranged to engage with each said pawl and retain the shield in the positions to which moved from said limit of movement.

35. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register; a second set of digit-indicators; means for causing the second set of indicators to register; a third set of indicators; means for moving the third set of indicators; a carriage having a series of members thereon arranged to coöperate with the indicator-moving means of the third set; means for causing the registering of one or more indicators of the first set to adjust an equal number of said members in positions relative to the digits registered; and means for causing the movement of registering on an indicator of the second set through each of its digit-spaces to cause said adjusted members to each engage an indicator-moving means of the third set and thereby cause its connected indicator to move through a number of digit-spaces equal to the digit registered on the first set when the said member was adjusted.

36. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register; a second set of digit-indicators; means for causing the second set of indicators to register; a third set of indicators; means for moving the third set of indicators; a carriage having a series of members thereon arranged to coöperate with the indicator-moving means of the third set; means for causing the registering of one or more indicators of the first set to adjust an equal number of said members in positions relative to the digits registered; and means for causing the movement of registering on an indicator of the second set through each of its digit-spaces to cause said adjusted members to each engage an indicator-moving means of the third set and thereby cause its connected indicator to move through a number of digit-spaces equal to the digit registered on the first set when the said member was adjusted; and means for resetting the indicators of the second set without affecting the said adjusted members.

37. In a calculator, the combination of a set of digit-indicators; means for causing the indicators to register; a second set of digit-indicators; means for causing the second set of indicators to register; a third set of indicators; means for moving the third set of indicators; a carriage having a series of members thereon arranged to coöperate with the indicator-moving means of the third set; means for causing the registering of one or more indicators of the first set to adjust an equal number of said members in positions relative to the digits registered; means for causing the movement of registering on an indicator of the second set through each of its digit-spaces to cause said adjusted members to each engage an indicator-moving means of the third set and thereby cause its connected indicator to move through a number of digit-spaces equal to the digit registered on the first set when the said member was adjusted; means for causing said latter operation after the registering of the indicators of the third set, to move the carriage and bring each said adjusted member into position for coöperation with an indicator-moving means next adjacent the one last operated; and thereby cause the subsequent movement of registering on an indicator of the second set, through each of its digit-spaces to cause said adjusted members to each engage a said latter indicator-moving means and thereby cause its connected indicator to move through a number of digit-spaces equal to the digit registered on the first set when the said member was adjusted.

707,653. ELECTRIC-LAMP SUPPORT. CLARENCE M. STEAD, Leeds, England. Filed Dec. 17, 1901. Serial No. 86,284. (No model.)



Claim.—1. The combination of a pendent piece *a c*, formed as an inverted cone or conoid over its lower part, and as a hollow cylinder over its upper part *c* having side strand-holes *d*; with an approximately flat lamp-plate *f*, having a central opening fitting over the cylindrical part *c* close to the base of the conical or conoidal part *a* and lamp-holder openings, and an annular conoidal reversible reflecting or shading part *g*; and a basin or dome-shaped cap-piece *i*, having a central opening and rim-recesses, and, all substantially as set forth.

2. The combination of a pendent piece *a c*, formed as an inverted cone or conoid over its lower part *a* and as a hollow cylinder over its upper part *c*; with a reversible lamp-plate *f* having a central opening fitting over the cylindrical part *c* close to the base of the conical or conoidal part *a* and lamp-holder openings, and a cone-shaped reflecting or shading part *g*; all substantially as set forth.

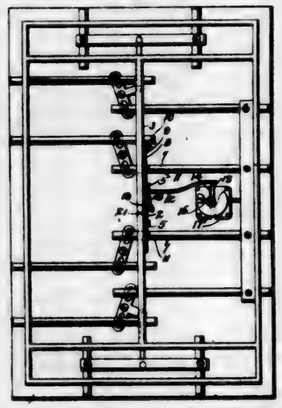
3. The combination of a pendent piece *a c* formed over its lower part *a* as an inverted cone or conoid and over its upper part as a hollow cylinder provided with end aperture *c* and strand side openings *d*; with an annular lamp-plate *f* having a central opening fitting over the cylindrical part *c* close to the base of the conical or conoidal part *a* and lamp-holder openings; and with a truncated cone-shaped reflector or shade *g* fitting with its smaller end the circumferential edge of the plate *f*, the said parts *f g* being independently reversible substantially as set forth.

707,654. TREATMENT OF CRUDE RUBBER. JAMES THAM, London, England, assignor to South Western Rubber Company, Limited, London, England. Filed Dec. 3, 1901. Serial No. 84,825. (Specimens.)

Claim.—1. A process of treatment of crude rubber consisting of the soaking of the rubber in a hot alkaline solution to remove deleterious matter from the exterior thereof, the submergence of the rubber in small pieces in a solvent of the matter to be removed, so that the interstices of the rubber are in contact with the said solvent, the subsequent submergence of the solvent-charged rubber in water or other inert liquid of less specific gravity than the solvent for such time as will allow the solvent to act upon the internal surfaces, and the removal of the dissolved matter and any residual free solvent by washing, substantially as described.

2. A process of treatment of crude rubber to remove deleterious matter therefrom, consisting of the supporting of the rubber in small pieces within a closed space, the submergence of the said rubber in a solvent of the said deleterious matter within the closed space, so that the surfaces of the interstices of the material are in contact with the solvent, the subsequent submergence of the solvent-charged rubber in water or other inert liquid of less specific gravity than the solvent for such a time as will allow the solvent to act upon the internal surfaces and the removal of the dissolved matter and any residual free solvent by washing, substantially as described.

707,655. SAFE-DOOR LOCK. HOVEY H. TRELOW, Petersburg, Ind., assignor of one-half to Philip K. Hearing, Petersburg, Ind. Filed Dec. 2, 1901. Serial No. 84,415. (No model.)



Claim.—1. In a safe-lock, a rest removably associated with the operating-spindle, in combination with emergency locking mechanism having means to engage the rest, and means operating automatically to secure the locking mechanism when in locked engagement with the bolts.

2. In a safe-lock, the combination with the operating-spindle and the bolts, of a bolt-locking plate, a removable rest supported by the spindle, and an arm on the locking-plate to engage the rest and thus hold the plate out of engagement with the bolts.

3. In a safe-lock, the combination with the operating-spindle and the bolts, of a spring-actuated locking-plate, a removable rest supported by the spindle, an arm on the locking-plate to engage the rest to hold the plate out of engagement with the bolt, and means operating automatically to lock the plate against lifting when in locked engagement with the bolts.

4. In a safe-lock, the combination with the bolts provided with recesses, of a spring-actuated locking-plate through which the bolts project, an arm carried by the plate, and a removable rest supported by the operating-spindle and upon which the arm bears to hold the locking-plate normally out of engagement with the recesses of the bolts.

707,656. TRUCK-BOLSTER. CORNELIUS VANDERBILT, New York, N. Y. Filed Feb. 17, 1902. Serial No. 94,412. (No model.)

Claim.—1. A truck-bolster comprising a plurality of flanged beams secured together by spring-seats which engage both faces of the webs of said beams at a plurality of points along their lengths, substantially as described.

2. A truck-bolster comprising a plurality of flanged beams, having their ends cut down by the removal of one flange and a portion of the web, said ends having parallel upper and lower edges and being secured together by spring-seats, substantially as described.

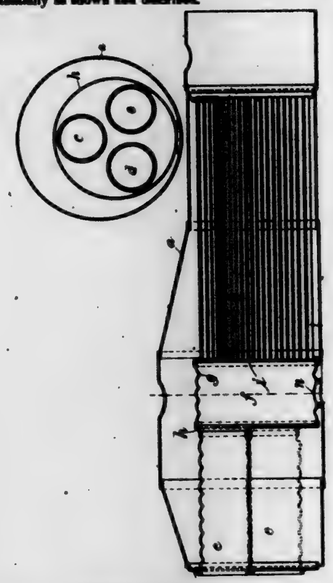
3. A spring-seat for a truck-bolster, comprising a base and upstanding walls forming a plurality of horizontal grooves to receive the webs of bolster-beams, substantially as described.

4. A stationally-constructed truck-bolster, comprising a plurality of beams, having center portions with upper and lower flanges, intermediate portions whose sectional areas decrease gradually, and end portions formed by cutting away one flange and a portion of the web on a line parallel to the other flange, substantially as described.

5. A spring-seat for a truck-bolster comprising a base having upstanding grooved side walls and upstanding end walls between and flush with said grooves, substantially as described.

707,657. LOCOMOTIVE-BOILER. CORNELIUS VANDERBILT, New York, N. Y. Filed Mar. 3, 1902. Serial No. 96,490. (No model.)

Claim.—In a locomotive-boiler, the combination with the boiler-shell and rear head, of a cylindrical, corrugated combustion-chamber having a flat circular rear head and three cylindrical, corrugated furnace-flues communicating with the combustion-chamber and supported by the rear head of the combustion-chamber and the rear head of the boiler and located within the circumference of the rear head of the combustion-chamber, one of the furnace-flues being disposed above and between the other two, substantially as shown and described.



707,658. BRAKE-BEAM. CORNELIUS VANDERBILT, New York N. Y. Filed Mar. 14, 1902. Serial No. 98,146. (No model.)

Claim.—1. In a brake-beam, a beam having an I-shaped body and integral T-shaped ends, brake-shoe heads fitted upon the webs of the ends, and a lever-bracket provided with a T-shaped opening therethrough whereby the bracket is fitted upon the web and flanges of one end of the body, and fastening means passing through the bracket and through the beam, substantially as described.

2. In a brake-beam, a beam having an I-shaped body and integral T-shaped ends, brake-shoe heads fitted upon the ends, and a lever-bracket provided with an opening therethrough whereby the bracket is fitted upon the body, and means for securing the bracket to the beam, substantially as described.

3. In a brake-beam, a flanged beam, brake-shoe heads secured to the ends of said beam, and a lever-bracket closely fitting the flange of the beam, a portion of the beam being cut away to permit the removal of the lever-bracket, substantially as described.

4. In a brake-beam, a flanged beam, brake-shoe heads secured to the ends of said beam, and a lever-bracket closely fitting the flange of the beam, a portion of the said flange being cut away to permit the removal of the lever-bracket, substantially as described.

5. In a brake-beam, a flanged beam having a flange at one end shorter than the web of the beam, a lever-bracket closely fitting the said flange, and brake-shoe heads fitted to the portions of the web beyond the flange extremities and spaced away from said extremities to permit the removal of the lever-bracket, substantially as described.

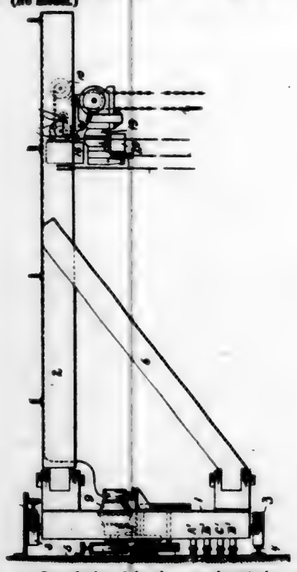
6. In a brake-beam, a flanged beam, a lever-bracket secured to said beam and brake-shoe heads fitted to the web of the beam and extending beyond the flange extremities, said heads being spaced away from said extremities to permit the removal of the lever-bracket, substantially as described.

707,659. SEAMED STOCKING. WALTER F. WARE, Camden, N. J., and WILMOT B. GABELMAN, Philadelphia, Pa. Filed Mar. 3, 1902. Serial No. 96,497. (No model.)

Claim.—1. A new article of manufacture, an elastic stocking comprising a substantially cylindrical leg portion having a selvage edge at its lower end and closed at the back by a longitudinal seam, a cylindrical foot portion having a selvage edge at its upper end closed by a seam at the bottom, a heel-band seamless at the rear having an upper selvage edge, the foot portion being stitched to the leg portion for substantially one-half their peripheries by elastic stitching the heel-band being attached to the other half of the periphery of the leg portion by elastic stitching and its ends to the adjacent foot portion, substantially as described.

2. A new article of manufacture, an elastic stocking comprising a substantially cylindrical leg portion having a selvage edge at its lower end and closed at the back by a longitudinal seam, tape covering said seam, a cylindrical foot portion having a selvage edge at its upper end and closed by a seam at the bottom, tape covering said seam, and a heel-band seamless at the rear having an upper selvage edge, the foot portion being stitched to the leg portion for substantially one-half their peripheries by elastic stitching, the heel-band being stitched to the other half of the periphery of the leg portion by elastic stitching, and its ends to the adjacent foot portion, substantially as described.

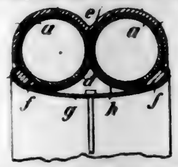
707,660. HOISTING APPARATUS. EDGAR H. WATLINGTON, Ridgewood, N. J., assignor to Sprague Electric Company, New York, N. Y., a Corporation of New Jersey. Filed Jan. 13, 1902. Serial No. 89,450. (No model.)



Claim.—1. In a device of the character described, a carrier, a boom carried thereby, a truck riding upon said boom, a motor carried by said carrier, another motor carried by said truck, means to shift the position of the truck upon said boom said means being carried by said truck, controllers for said motor said controllers being also carried by said truck and depending operating-cords for said controllers and for said shifting means.

2. In a device of the character described, a traveling carrier, a motor mounted thereon for operating the same, a boom carried by said carrier, a truck riding upon said boom, a motor carried by said truck for operating said truck, a hoisting apparatus carried by said truck, mechanism for operating said hoisting apparatus, controllers carried by said truck for operating the said motors and the said hoisting operating mechanism, and depending operating-cords for said controllers and said hoisting mechanism, substantially as described.

707,661. PNEUMATIC TIRE. MORITZ WEISS, Vienna, Austria-Hungary. Filed May 14, 1902. Serial No. 107,208. (No model.)



Claim.—1. The combination with a rim, two connecting air-tubes seated therein, a cover inclosing the tubes, adapted to be secured to the edges of the rim and a ring between the two tubes above the transverse center line thereof adapted to draw said cover below the bearing-surfaces of the tubes, for the purpose set forth.

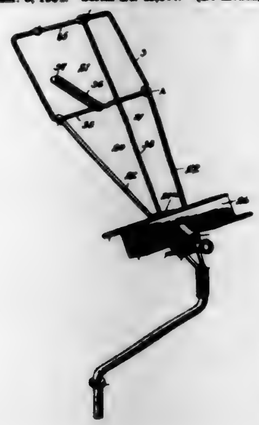
2. The combination with a rim, of air-tubes seated therein, a cover inclosing the tubes, a lining to the cover adapted to surround each of said tubes, and flanges on the edges of the cover adapted to clamp the lining, for the purpose specified.

3. The combination with a vehicle-rim, of a ring seated therein, two air-tubes supported on the ring, a cover inclosing the tubes, a lining interposed between the cover and tubes and adapted to surround the latter, and flanges on the edges of the cover adapted to clamp the outer edges of the lining between said flange and rim, for the purpose specified.

4. The combination with a vehicle-rim, of a ring formed with two concave surfaces centrally mounted in the rim, air-tubes mounted in the rim and resting on both surfaces of said ring, a cover inclosing said tubes, linings secured to the cover adapted to surround each of the tubes, flanges secured to the cover adapted to clamp the edges of both linings, for the purpose specified.

5. The combination with a metallic vehicle-rim provided with side flanges, of a saddle-shaped ring centrally mounted in said rim, air-tubes mounted on said ring, a cover inclosing said tubes, flanges formed on the edges of the cover adapted to take under the rim-flanges, linings secured to the cover adapted to surround each of the tubes and be clamped by the cover-flanges, and a ring embedded in said cover to draw the central part thereof below the bearing-surfaces of the air-tubes, for the purpose specified.

707,662. COPY-HOLDER. JAMES C. WHITTEMARVER, Cameron Mo. Filed Mar. 5, 1901. Serial No. 49,577. (No model.)



Claim.—1. In a copy-holder, the combination with a rack comprising a lower stationary section and an upper movable section pivoted to the upper end of the stationary section, of a support for the rack attached to the lower section, a copy-supporting device also secured to the lower section, and means for holding the upper section in angular relation to and in rear of the lower section, whereby said upper section will constitute a rest or shelf for the leaves of copy thrown backwardly over the top of the lower section.

2. In a copy-holder, the combination with a rack comprising a lower stationary section, and an upper movable section pivoted to the upper end of the stationary section, of a support for the rack attached to the lower sections, a copy-supporting device also secured to the lower section, and means for holding the two sections in alinement, said means also serving to hold the upper section in angular relation to and in rear of the lower section, whereby said upper section will constitute a rest or shelf for the leaves of copy thrown backwardly over the top of the lower section.

3. In a copy-holder, the combination with a rack comprising a lower stationary section and an upper movable section pivoted to the lower stationary section, of a support for the rack attached to the lower section, a copy-supporting ledge extending across the lower section, a locking-rod pivoted to the upper section and movably engaged with the lower section, and stops mounted upon the movable upper section and engaging the rod to hold it against movement and thereby secure the movable section either in alinement with the stationary section or in angular relation thereto.

4. In a copy-holder, the combination with a support, of a rack comprising a main section mounted upon the support, a supplementary section pivotally connected to the upper end of the main section, a locking-rod pivotally and slidably connected to the upper end of the supplementary section and having its lower end engaging the main section, and holding means for the rod located between the engaging portions thereof and arranged to detachably engage said rod to hold it against its pivotal movement and maintain the supplementary section in cooperative relation with the main section.

5. In a copy-holder, the combination with a support, of a rack comprising a main section mounted upon the support, and having a pair of diverging side rods provided with hinge-eyes at their upper ends, said main section carrying a supporting-ledge, a supplementary section comprising a frame having a cross-bar which passes through the eyes of the main section, whereby the two sections are pivotally connected, said cross-bar being provided with an offset portion forming a guide-slot, and a locking-rod pivotally and slidably connected to the upper end of the supplementary section and slidably engaging the main section at its lower portion, said rod being adapted to engage the cross-bar of the supplementary section to hold the two sections against relative movement, and being also adapted to aline with the guide-slot to permit the backward swinging of the supplementary section.

6. In a copy-holder, the combination with a rack having a supporting-ledge contiguous to its lower end, of a stem passing transversely through the rack, and having a frictional engagement therewith, and a spring carried by the stem and adapted to bear against the copy placed upon the ledge.

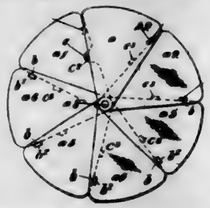
7. In a copy-holder, the combination with a rack having a supporting-ledge at its lower end, and provided below said ledge with a transversely-projecting sleeve, of a stem slidably mounted in said sleeve and projecting from the front side of the rack, and an upstanding bearing-spring secured to the projecting end of the stem, and adapted to engage and bear against the copy placed upon said ledge.

707,663. RAIL-BOND. HOSEA F. WHITON, Hingham, Mass. Filed Feb. 3, 1902. Serial No. 92,342. (No model.)

Claim.—1. A rail-bond composed of a laminated strip having flat feet and an intermediate extensible portion, solder interposed between the several layers composing said flat feet, a rivet passing through said layers and a strip of sheet-solder attached at one end to the bottoms of said flat feet, substantially as described.

2. A rail-bond composed of a laminated strip having flat feet and an intermediate extensible portion, solder interposed between the several layers composing said flat feet, a rivet passing through said several layers and a strip of sheet-solder attached at one end to the bottoms of said flat feet having a hole through it for the protruding end of said rivet, substantially as described.

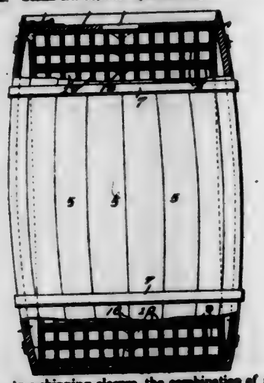
707,664. ASH-TRAY AND ADVERTISING DEVICE. OLIVER J. WILLMOT, Malvern, England. Filed Nov. 8, 1901. Serial No. 81,563. (No model.)



Claim.—1. An ash-tray composed of separate superposed sectoral parts pivotally connected at the smaller ends, said separate parts being curved downwardly midway and transversely thereof and said parts being also provided with means for holding them in an extended or circular tray form, consisting of recesses and lugs or projections adapted to enter said recesses, substantially as shown and described.

2. An ash-tray composed of separate superposed sectoral parts pivotally connected at the smaller end thereof, said parts being curved downwardly midway thereof and transversely thereof, and said parts being also provided with means for holding them in an extended position or in tray form, said parts being also adapted to be folded together one above another and to be extended into a circular or tray form.

707,665. SHIPPING-CRATE. ROBERDEE R. WILLIAMS, Nevada, Mo., assignor of one-fourth to Anson Lynn Wood, Nevada, Mo. Filed Feb. 28, 1902. Serial No. 96,144. (No model.)



Claim.—1. In a shipping-closure, the combination of a casing having sides that are bulged intermediate the ends of such closure, vertical interior guides extending through the entire length of said casing, and a plurality of superimposed disks having recesses engaging said guides whereby the said disks are movable through the entire length of the casing, substantially as set forth.

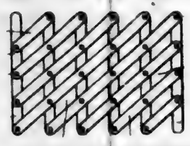
2. In a shipping-closure the combination of a casing having bulging sides, vertical interior guides extending through said casing, superimposed disks having recesses engaging said guides, and openings in said disks forming handles and admitting of the passage of ventilation therethrough, substantially as set forth.

3. In a shipping-closure a casing having apertures through the ends and provided with vertical interior guides in combination with a series of superimposed disks having recesses engaging said guides and provided with approximately centrally located ventilating-openings forming handles, and collular-castings interposed between said disks and separating the same, substantially as set forth.

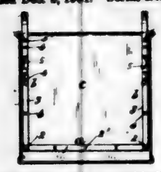
4. In a shipping-closure, a casing, a series of superimposed trays supported within said casing and formed with transverse division-strips forming compartments thereon, a cover to said casing having a depending flange engaging said casing when in position thereon, and adapted to engage said compartments on said tray and afford means for receiving and supporting the contents of one of said trays when inverted, substantially as described.

707,666. ELECTRODE FOR STORAGE BATTERIES. HENRY WOODWARD, London, England. Filed Jan. 15, 1901. Serial No. 43,316. (No model.)

Claim.—An accumulator-plate comprising a plurality of strips crossing each other and pivotally connected together to permit expansion and contraction.

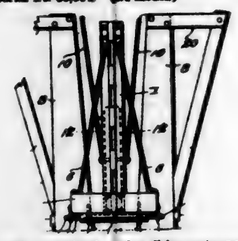


707,667. ATTACHMENT FOR WASHBOILERS. SAMUEL B. WOODFORD, Imperial, Pa., assignor of one-half to Carl B. Hamilton, Coraopolis, Pa. Filed Dec. 3, 1901. Serial No. 84,464. (No model.)



Claim.—The combination with a washboiler, of a clothes-holder consisting of a bottom grate, and two opposite side grates hinged to the bottom grate, the said grates having respectively two parallel bars intersected at right angles by rods fixed to the said bars, and means for adjustably attaching the side grates to the upper edge of the boiler for holding the bottom grate at a varying distance from the bottom of the boiler, substantially as described.

707,668. GATE. WILLIAM H. WRIGHT, Cadiz, Ohio. Filed Jan. 14, 1902. Serial No. 89,694. (No model.)



Claim.—1. The combination of a tilting gate, posts located at opposite sides of the gate and arranged adjacent to the same, a transverse block or bar secured to the rear end of the gate and arranged in rear of the posts and provided with bearings, a pintle-rod located in rear of the posts and arranged in the bearings and secured to and connecting the said posts, and means for operating the gate, substantially as described.

2. The combination of a tilting gate, the tapered posts located at opposite sides of the gate and arranged close to the same, the transverse block or bar secured to the gate at the bottom thereof and located in rear of the posts and provided with bearings, a pintle-rod arranged in the bearings and provided at its ends with arms secured to the posts, inclined fulcrum-bars extending upward from the outer sides of the posts and connected with the same at the upper portions thereof, operating-levers fulcrumed on the fulcrum-bars, and rods connecting the inner ends of the operating-levers with the gate, substantially as described.

707,669. DETACHABLE HANDLE FOR CASKETS, BOXES, &c. CHARLES YOUNG, Chicago, Ill. Filed Oct. 11, 1901. Serial No. 78,312. (No model.)

Claim.—1. A detachable handle or lifter comprising the combination with a handle provided with a flat contact-surface and an interlocking lug, of a plate having a slot therein, said slot comprising an enlarged portion wherethrough the lug can be inserted, another portion wherein the lug will be held, and a connecting portion formed so the lug can be passed therethrough by twisting, and whereby the lug will be held against withdrawal by longitudinal movement in the slot.

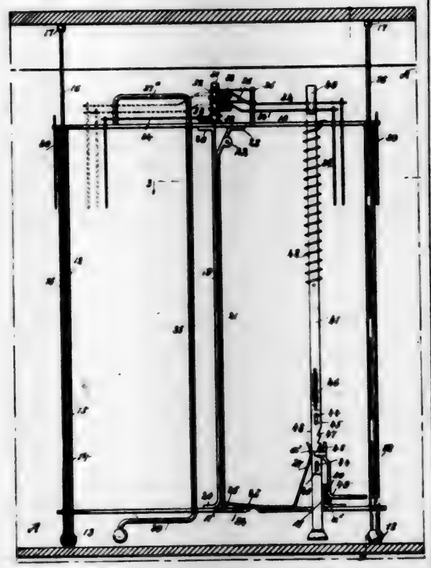
2. A detachable handle or lifter comprising the combination with a handle, provided with a flat contact-surface, and an interlocking lug having beveled sides, of a plate having a slot therein, said slot having sides correspondingly beveled to hold said lug, said slot comprising an enlarged portion wherethrough the lug can be inserted, another portion out of alinement with said enlarged portion and a connecting portion formed so the lug can be passed therethrough by twisting, and whereby the lug will be held against withdrawal by longitudinal movement in the slot.

3. A detachable handle or lifter comprising the combination with a handle provided with a flat contact-surface and with a lug having beveled sides, of a plate having a slot therein, said slot having correspondingly-beveled sides wherewith said lug will engage and having an enlarged portion, wherethrough said lug can be inserted, said plate having a flat contact-surface wherewith the handle will engage, said lug being of substantially the same thickness as the plate, so the inner surface of the lug will form a surface flush with the inner side of the plate, and which will engage the plane surface of the casket or box whereto the plate may be secured.

707,670. TREATMENT OF REFRACTORY BRICKS. SYLVESTER ECKENBRECHT, Staasfurt, Germany. Filed May 9, 1901. Serial No. 58,581. (No specimens.)

Claim.—The process herein described of increasing the refractory properties of baked bricks and the like, which consists in saturating them with a solution of magnesium chlorid, then subjecting them to the action of heat to dissolve the salts and evolve the hydrochloric acid, substantially as set forth.

707,671. MUSIC-LEAF TURNER. GEORGE E. ADAMS, Glens Falls, N. Y., assignor to William D. Earl, Lowell, Mass. Filed Aug. 23, 1901. Serial No. 73,007. (No model.)



Claim.—1. In a music-leaf turner, a frame comprising upper and lower cross-bars, tubular side bars connecting the cross-bars and a spring-controlled rod located in each side bar, each rod extending beyond the upper portion of the frame and terminating in a head, and a foot located at the lower end of each tubular side bar, for the purpose set forth.

2. In a music-leaf turner, a frame, a post carried by the frame, a series of spring-controlled music-turning arms mounted to turn on said post, clamps carried by the said arms, a sliding controlling-bar adapted to engage and hold the said arms at one side of the frame, a spring for the controlling-bar and tending to move said bar upward out of engagement with the turning-arms, and a releasing device connected with the controlling-bar for releasing the said bar to permit it to be moved upward by its spring at predetermined intervals, as set forth.

3. In a music-leaf turner, the combination, with a frame, a post carried by the upper portion of the frame, spring-controlled music-carrying arms mounted on the said post, and clamps carried by the said arms, the clamps consisting of downwardly-extending parallel rods, of a controlling-bar mounted to slide in the frame, extending above and below it, a spring exerting an upward tension on the said controlling-bar, a hook located at the upper portion of the said controlling-bar, engaging with the music-carrying arms when at the right-hand side of the frame, a slide having limited movement on the controlling-bar, which slide is provided with teeth in one of its longitudinal edges, corresponding with teeth produced in a corresponding edge of the controlling-bar, a laterally-reciprocating releasing-lever provided with a yoke which receives between its members the slide and the controlling-bar, the said lever having a projection adapted for engagement with the teeth on the slide or the teeth on the controlling-bar, and a spring attached to the controlling-bar and to the said slide, adapted to draw the slide upward after the controlling-bar has been moved in the same direction.

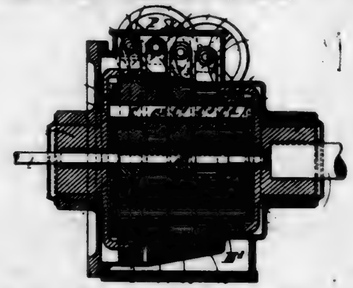
4. In a music-leaf turner, the combination, with a frame having an opening in its lower portion, a central clamping-bar attached to the top and bottom of the frame, a parallel clamping-bar free at its lower end and having hinged connection with the frame at its upper end, and a spring secured to the frame adjacent to the opening thereof and adapted for engagement with the free end of the second clamping-bar to hold it in close relation to the fixed clamping-bar, as and for the purpose specified.

5. In a music-leaf turner, the combination with a frame, and a plurality of spring-controlled turning-arms mounted on the frame, of a sliding and spring-pressed controlling-bar mounted in the frame and adapted to hold the turning-arms at one side of the frame, a spring-pressed slide having limited movement on the bar, and an operating-lever adapted to engage either the bar or slide, as and for the purpose set forth.

6. In a music-leaf turner, the combination with a frame, and a plurality of spring-actuated turning-arms mounted on the frame, of a sliding and spring-pressed controlling-bar mounted in the frame and adapted to hold the turning-arms at one side of the frame, said bar being provided with teeth, a spring-pressed slide having limited movement on the bar and provided with teeth adapted to register with the teeth of the bar, and an operating-lever provided with a projection or tooth adapted to engage the teeth of either the bar or slide, as set forth.

7. In a music-leaf turner, the combination with a frame, and a plurality of turning-arms mounted on the frame, of a sliding and spring-pressed bar provided with a hook at its upper end with which the turning-arms engage, and with teeth at its lower portion, a spring-pressed slide mounted on the bar to have limited movement thereon, and a pivoted and spring-pressed operating-lever having a yoke at its upper end between the members of which the bar and slide extend, and with a projection adapted to engage the teeth of either the bar or slide, as set forth.

707,672. WHEEL-GEAR. GEORGE S. BAKER, London, England. Filed Dec. 3, 1901. Serial No. 84,667. (No model.)



Claim.—1. In a speed-gear the combination of a driving-pinion, a compound planet-pinion gearing therewith having several portions of greater and of less diameter than the last portion, an internally-toothed rotatable ring engaging with each portion, a driven shaft connected to the last ring and a locking device for each of the other rotatable rings.

2. In a speed-gear the combination of a driving-pinion, a compound planet-pinion gearing therewith having several portions of greater and of less diameter than the last portion, rotatable means for supporting the compound pinion, an internally-toothed rotatable ring engaging with each portion, a driven shaft connected to the last ring and a locking device for each of the other rotatable rings.

3. In a speed-gear the combination of a driving-shaft, a toothed

pinion mounted thereon, a plurality of compound planet-pinions gearing therewith each having several toothed portions of greater diameter, and one toothed portion of smaller diameter than the last portion, an internally-toothed rotatable ring engaging with each portion, a driven shaft positively connected to the last ring and a locking device for each of the other rotatable rings.

4. In a speed-gear the combination of a driving-shaft, a toothed pinion mounted thereon, a plurality of compound planet-pinions gearing therewith each having several toothed portions of greater diameter and one toothed portion of smaller diameter than the last portion, a rotatable floating frame supporting the compound pinions, an internally-toothed rotatable ring engaging with each portion, a driven shaft positively connected to the last ring and a locking device for each of the other rotatable rings.

5. In a speed-gear the combination of a driving-shaft, a toothed pinion mounted thereon, a plurality of compound planet-pinions gearing therewith each having several toothed portions of greater diameter and one toothed portion of smaller diameter than the last portion, a rotatable floating frame supporting the compound pinions, an internally-toothed rotatable ring engaging with each portion a driven shaft positively connected to the last ring and a band-brake, consisting of a split ring encircling each of the other rotatable rings.

6. In a speed-gear the combination of a driving-shaft, a toothed pinion mounted thereon a plurality of compound planet-pinions gearing therewith each having several toothed portions of greater diameter and one toothed portion of smaller diameter than the last portion, a rotatable floating frame supporting the compound pinions, an internally-toothed rotatable ring engaging with each portion, a driven shaft positively connected to the last ring, a casing inclosing the gear, and a band-brake consisting of a split ring encircling each of the other rotatable rings, the brakes being cast in one piece with the casing.

7. In a speed-gear the combination of a driving-shaft, a toothed pinion mounted thereon, a plurality of compound planet-pinions gearing therewith each having several toothed portions of greater diameter and one toothed portion of smaller diameter than the last portion a rotatable floating frame supporting the compound pinions an internally-toothed rotatable ring engaging with each portion, a driving-shaft positively connected to the last ring, a casing inclosing the gear, a band-brake consisting of a split ring encircling each of the other rotatable rings the brakes being cast in one piece with the casing and a tightening-screw engaging with lugs on each split ring projecting through an aperture in the casing.

707,673. SHAFT OR AXLE BEARING. JOHN C. BLEVNEY, Hoxart, N. J. Filed Dec. 20, 1902. Serial No. 41,499. (No model.)

Claim.—1. The combination with a shaft and its box, one having a rotary relation to the other, of a thin, flexible and resilient sheet of hard metal loosely interposed between said shaft and box and extending in a single piece substantially around the whole periphery of the shaft, the said sheet being free to either turn with the rotary member, or to remain at rest with the stationary member, substantially as set forth.

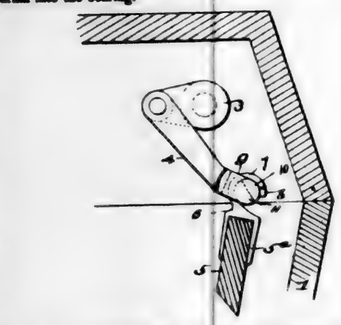
2. The combination with a shaft and its box, one having a rotary relation to the other, of a thin, flexible and resilient sheet of hard metal loosely interposed between said shaft and bearing, the said sheet of hard metal, being free to turn with the rotary member, substantially as set forth.

707,674. COUPLING. JOHN R. GARVIN, Augusta, Ky., and JOSEPH R. HAMMERLE, Cincinnati, Ohio, assignors to Ernst H. Hunnefeld, Cincinnati, Ohio. Filed Dec. 23, 1901. Serial No. 86,987. (No model.)

Claim.—1. A coupling comprising two members, one member having a journal provided with a transverse groove, and the other member having an open bearing provided at one end with a tongue concentric with and having a bearing on said journal.

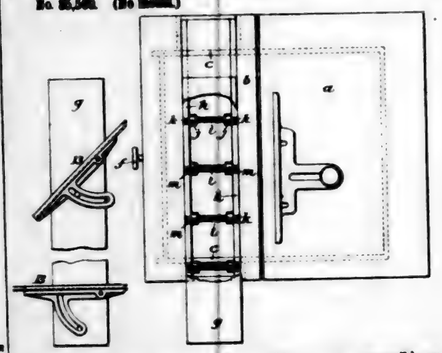
2. A coupling consisting of two members, one having a bearing thereon open on one side and a tongue projecting from one end of said open portion, the other member having a journal grooved or recessed to allow the passage of the tongue and permit the insertion of the journal into the bearing.

3. A coupling consisting of two members, one having a bearing thereon open on one side and an integral tongue projecting from said bearing, the other member comprising a pinion having a slotted enlargement at one end projecting at an angle thereto, a journal extending across the bifurcated end of the pinion and grooved or recessed in one side to receive the tongue when alined therewith and permit the insertion of the journal into the bearing.



4. The combination with a device to be moved and a crank-shaft, of a pitman connected at one end to the crank-shaft, a journal at the other end of said pitman, a bearing secured to said device open in one side and having a tongue projecting therefrom and said journal grooved to permit its insertion into the bearing when the pitman is disposed so as to aline the groove with the tongue on the bearing.

707,675. CIRCULAR SAWING MACHINE. HENRY J. OLBERS, Toledo, Ohio; Ellen A. Olbers and Irving W. Olbers, executors of said Henry J. Olbers, deceased; Irving W. Olbers, administrator, assignor to Ellen A. Olbers, Toledo, Ohio. Filed Dec. 12, 1901. Serial No. 85,969. (No model.)



Claim.—1. In a circular sawing machine, a rotary reversible saw-frame, means for reversing the same, revolubie saws in one plane carried by said frame, journal-supports for said frame on each side of the plane of the saws, and a journaled yoke, embracing the saw plane, connected with said frame, and forming with its journal the outer support of said saw-frame, substantially as specified.

2. In a circular sawing machine, a rotary reversible saw-frame, means for reversing said frame, revolubie saws in one plane carried by said frame, journal-supports for said frame, on each side of the plane of the saws, a journaled yoke embracing the saw plane connected with said frame, forming with its journal the outer support of said saw-frame, and means for adjustably securing said yoke to said frame at an angle in any desired axial plane relative to the frame plane, substantially as specified.

3. In a circular sawing machine, a journaled reversible saw-frame, carrying revolubie saws in one plane, a yoke embracing said saw plane, connecting the journaled portions of said saw-frame, a sleeved connection rotarily adjustable, between said yoke and said frame, and means for releasing and clamping said sleeved connection in any desired angular position between the yoke plane and the frame plane respectively, substantially as specified.

4. In a circular sawing machine, a rotary reversible saw-frame carrying revolubie saws mounted in one plane, a table having a fixed portion, a movable portion adjustable toward and from the fixed portion, a sliding portion between said fixed and adjustable portions, movable in a direction parallel to the plane of the saws, and means for positively adjusting the distance between the adjustable and fixed portions, substantially as specified.

5. In a circular sawing machine, a main frame, a rotary reversible saw-frame carrying revolubie saws mounted in one plane, a table having a fixed portion, a movable portion adjustable toward and from the fixed portion, a sliding portion between said fixed and adjustable portions, mounted on the latter, movable in a direction parallel to the plane of the saws, and laterally adjustable with said adjustable portion to regulate the width of the saw crevice, and pivotal means for tilting said tables and retaining them in a tilted position, substantially as specified.

6. In a circular sawing machine, a rotary reversible saw-frame carrying revolubie saws mounted in one plane, a worm-gear axially mounted on said reversible frame, a resilient worm-shaft carrying a worm in engagement with said worm-gear, a means for operating said worm-shaft, and bearings for said worm-shaft, one of which is adjustable and located intermediate between the other bearing and the worm, at some distance from the latter, whereby when the worm is adjusted in close mesh with the worm-gear it is retained in elastic contact therewith by the resiliency of the worm-shaft, substantially as specified.

7. In a circular sawing machine, a main frame, a rotary reversible saw-frame, carrying revolubie saws mounted in one plane, a table having a fixed portion, a movable portion adjustable toward and from the fixed portion, a sliding portion in substantially the same plane with the said adjustable portion, movable on rollers in a direction at right angles to the movement of the adjustable portion, and a cutting-off gage mounted on said sliding portion, substantially as specified.

8. In a circular sawing machine, reversible saws mounted in one plane, a fixed table, a movable table adjustable toward and from the fixed table, a transversely-sliding table between said fixed and adjustable tables, adjustable with the latter, supporting-rollers beneath said sliding table, carried on said adjustable table, and means for maintaining said sliding table and rollers in operative parallelism with the plane of the saws, substantially as specified.

707,676. PERMUTATION-PADLOCK. DAVID H. COOGLER, Concordia, Kans. Filed May 13, 1902. Serial No. 107,070. (No model.)

Claim.—1. In a lock the combination of a shackle having a movable member provided with notches, a series of rotary tumblers mounted on the shackle and arranged to engage the notches of the movable member, and a rotary setting-ring adjustably mounted on the shackle and provided with an indicator and adapted to shift the same to change the combination, substantially as described.

2. In a lock the combination of a shackle having a movable member provided with notches, a series of rotary tumblers provided with characters, a rotary setting-ring adjustably mounted on the shackle and having an indicator and capable of rotation for shifting the position of the same, and means for clamping the setting-ring in its adjusted position, substantially as described.

3. In a device of the class described, the combination with a permutation-lock having a series of rotary tumblers provided with characters, of a rotary setting-ring adjustably mounted on the shackle and provided with an indicator and capable of rotation to shift the position of the indicator to change the combination, and means for securing the setting-ring in its adjusted position, substantially as described.

4. In a lock the combination of a shackle having a movable member and provided with a grooved core, said shackle being also provided at the inner end of the core with an annular flange, a flanged setting-ring adjustably mounted on the flange of the core and provided with an indicator, a clamping device for holding the setting-ring in its adjusted position, a series of rotary tumblers mounted on the core and provided with notches or recesses and means for securing the tumblers on the core, substantially as described.

5. In a lock the combination, of a shackle having a grooved core, a series of tumblers mounted on the core and provided with recesses, a rotary setting device having an indicator and a key for holding the tumblers while the setting device is being adjusted, substantially as described.

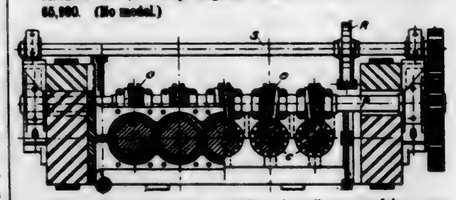
6. A lock provided with outer tumblers and having a pair of inner tumblers of greater diameter than the outer tumblers, the latter being of greater diameter than the adjacent fixed portions of the lock to provide projecting edges, substantially as described.

707,677. PAINT. FREDERICK H. GRAM, Murfreesboro, Tenn. Filed Oct. 10, 1901. Serial No. 78,246. (No specimens.)

Claim.—1. The composition herein described, consisting of carbonized and pulverized raw cotton, and coal-tar in the proportions substantially as specified.

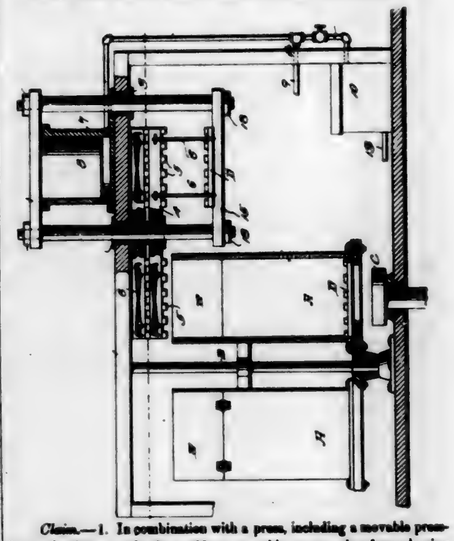
2. The process of compounding a carbon-paint composition which consists in carbonizing raw cotton, then pulverizing the carbonized cotton, and then thoroughly mixing the carbonized cotton with coal-tar, in the proportions as specified.

707,678. METALLIFEROUS STAMPING MILL OR MACHINE. JAMES G. DAW, Llanelly, England. Filed June 25, 1901. Serial No. 65,990. (No model.)



Claim.—In a stamp-mill, a plurality of anvils arranged in a row, worm-gears connected with said anvils, a shaft carrying a plurality of worms meshing with said worm-wheels, pawl-and-ratchet mechanism for rotating said shaft, and stamps cooperating with said anvils, substantially as described.

707,679. COTTON-COMPRESS. JESSE L. DARRAS, Whitewright, Tex., assignor of one-half to McMillin & Lively, Whitewright, Tex., a Firm. Filed Mar. 17, 1902. Serial No. 98,572. (No model.)

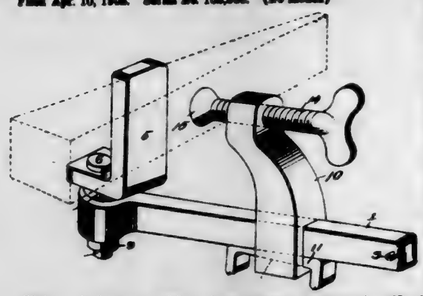


Claim.—1. In combination with a press, including a movable press-box, a fixed support having guides, a movable compressing-frame having parallel guide-bars operating in said guides, a fluid-pressure mechanism disposed between said guides on said support and connected to an element of the movable frame at a point intermediate the guide-bars thereof, and a revolubie element mounted on one of the guides to carry a bale from the press to the compressing-frame, for the purpose set forth, substantially as described.

2. In combination with a press, including a movable press-box, a fixed support having guides, a movable compressing-frame having parallel guide-bars operating in said guides, a fluid-pressure mechanism disposed between said guides on said support and connected to an element of the movable frame at a point intermediate the guide-bars thereof and a plurality of revolubie elements independently mounted for revolution on one of the guides, for the purpose set forth, substantially as described.

3. In combination with a press, including a movable press-box, a fixed support having a guide, a movable compressing-frame having an element to travel in said guide, means to operate said compressing-frame, and a revolubie element mounted on the guide to carry a bale from the press to the compressing-frame, substantially as described.

707,680. CLAMP. WILLIAM T. DE WORTH, Bordentown, N. J. Filed Apr. 10, 1902. Serial No. 102,208. (No model.)



Claim.—A clamp comprising a beam having a transversely-orificed head, an L-shaped head-block having its longer member disposed at right angles to the beam and its shorter member disposed parallel therewith and provided with an orifice of greater diameter than that in the head, a bolt having that portion of its length engaging the orifice in the head-block circumferentially enlarged, presenting thereby a shoulder to rest upon the beam and to limit the movement of the bolt with relation thereto, a washer interposed between the head-block and the beam, the washer being of a thickness to permit free swiveled movement of the head-block without rocking, thereby to render it automatically adjustable to tapered surfaces, a tail-block carrying a clamping-screw, and a locking-wedge associated with the tail-block and provided with lateral extensions to present means for locking and unlocking the wedge, substantially as and for the purpose specified.

707,681. SHELL-BASE FOR CARTRIDGES. ARTHUR T. DUNCAN, Clinton, Mo. Filed Apr. 26, 1901. Serial No. 57,633. (No model.)

Claim.—As a new article of manufacture, a removable base for a cartridge-shell, said base being made of paper or other light material, of cylindrical form, with unobstructed peripheral surface, whereby it is adapted to be readily fitted in and removed from the breech of a cartridge-shell, said base having a funnel-shaped powder-receiving cavity on one side and a central bore communicating with said cavity, said bore being adapted to receive the primer-chamber in the base of the cartridge-shell, the surface of the base which is exposed to the powder being lined with thin metal, substantially as described.

707,682. FASTENING DEVICE. FREDERIC A. FAIRBROTHER Jr., Providence, R. I. Filed Nov. 14, 1901. Serial No. 82,304. (No model.)

Claim.—In a fastening device, the combination of male and female members one of which is yielding and provided with opposite studs, and the other with engaging shoulders adapted to be engaged by said studs, the latter member being also provided with oppositely-inclined edges which serve to cause the release of the members from each other, substantially as described.

707,683. ANCHORING-POST. MARY F. FARWELL, Astoria, Ill., assignor to Country Home Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 1, 1901. Serial No. 70,504. (No model.)

Claim.—1. The combination with a hollow post, of a bar thereon provided at one end with a claw and at the other end with an enlargement serving to fill the bore of the post and constituting a butt to be struck in forcing the claw into the surrounding soil, substantially as described.

2. The combination with a hollow post provided at its lower end with an aperture, of a covering for the said aperture, a bar located within the post, and a claw provided upon the bar and adapted by a movement of the bar to be forced through the said covering into the surrounding soil, substantially as described.

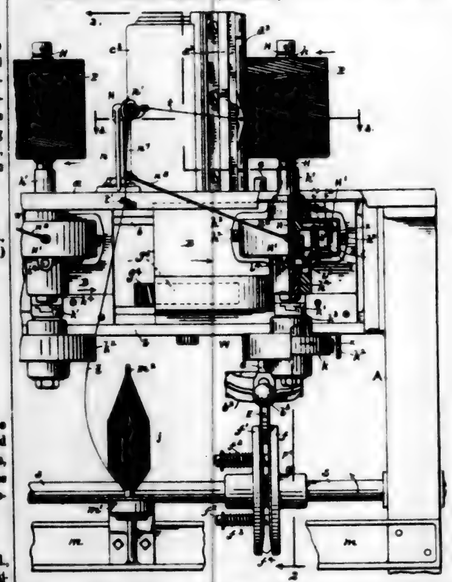
3. The combination with a hollow post, provided at its lower end with an aperture, of a bar in the post, a claw provided upon the bar and adapted to be forced through the said aperture, and an anchoring screw-cap for engagement with the upper end of the post, substantially as described.

4. The combination with a hollow anchor-post, provided at its lower end with an aperture, of a bar in the post, a claw provided upon the bar and adapted to be forced through the said aperture, and a screw-cap for engagement with the upper end of the post and provided with an aperture for engagement with a rope or cable, substantially as described.

5. A post comprising a tubular structure having its lower end provided with an earth-penetrating device and also provided with an aperture and made hollow throughout its length above such device, a bar or rod arranged within said tubular structure and provided at its lower end with a claw or like device adapted for projection through said aperture in the post, the said bar or rod extending to substantially the top of the post when the claw is projected, and means for engaging the bar or rod and locking the same in the post after the claw has been projected, substantially as set forth.

6. A tubular or hollow post, containing an anchoring device adapted for projection from the post into the earth and a stop or abutment having interlocking engagement with the post so as to be prevented from removal by longitudinal slippage and engaging the anchoring device to prevent the retraction of the anchoring device and means for attaching a rope or cable to the post, substantially as described.

707,684. WINDING-MACHINE. RISDON C. FAY, Pawtucket, R. I., and FREDERICK L. FAY, East Brookfield, Mass., assignors to the Easton & Burnham Machine Company, Pawtucket, R. I. Filed Oct. 10, 1901. Serial No. 78,315. (No model.)



Claim.—1. In a winding-machine of the class described, the combination of a revolvable spindle adapted to carry a cop tube or quill on which the cop is to be built, a reciprocating yarn-guide for laying the yarn in successive spiral convolutions and layers in building up the cop, a freely-turning guide-roll located contiguous to said yarn-guide and spindle, a plate or frame member carrying said spindle capable of moving in a lateral direction in unison with and by means of the increasing diameter of the cop and having the peripheral surface of the latter in substantially continuous engagement with said guide-roll, a tension device for the yarn arranged whereby the tension is automatically relaxed as the cop increases in size, and driving mechanism for actuating said spindle having its speed automatically reduced by said increase in the cop's diameter.

2. In a winding-machine, the combination with a suitable driving-pulley, a cop-spindle and a variable pulley secured thereon, of an initial driven pulley, an endless driven belt leading from the latter pulley to said cop-spindle pulley, and a movable shipper wheel or member interposed between and adapted to be in simultaneous engagement with the driving and driven pulleys, substantially as hereinbefore described and for the purpose set forth.

3. In a winding-machine, the combination with the revolvable cop-spindle, a slidable plate or carriage having said spindle mounted therein, and a reciprocating guide for laying the yarn on the cop, of suitably-mounted yielding driving and driven pulleys through which power is transmitted to said spindle, a shipper-wheel interposed between and in frictional engagement with said pulleys, a movable arm or lever carrying said shipper-wheel, and means coacting with said carriage and lever arranged whereby the movement of the carriage, due to the increasing diameter of the cop, automatically changes the position of the shipper-wheel with respect to the said pulleys and produces a variation in the speed of the cop-spindle, substantially as described.

4. In a winding-machine, the combination of a vertically-arranged revolvable cam, a reciprocating yarn-guide actuated by said cam adapted to lay the yarn on the cop, a vertical cop-carrying spindle arranged to automatically move in a lateral direction away from the cam as the cop increases in size, an endless belt arranged to simultaneously actuate said cam and cop spindles, and mechanism substantially as described for automatically reducing the speed of the traveling belt as the cop increases in diameter.

5. In a winding-machine, the combination with the cop-spindle and a movable plate or frame carrying said spindle, of suitably-mounted driver and driven pulleys, a movable shipper device arranged to engage said pulleys having its action controlled by said plate, and a driving-belt mounted on said driven pulley and rotating the cop-spindle.

6. In a winding-machine, the combination of a revolving cam-C having a fixed axis, a vertically-reciprocating yarn-guide *d* in engagement with and having its movements controlled by said cam, a suitably-mounted revolvable cop-spindle capable of lateral movement in unison with and by means of the gradually-increasing diameter of the cop, and a freely-turning guide-roll d^2 located contiguous to the yarn-guide and in substantially continuous engagement with the cop's surface.

7. In a winding-machine, the combination of oppositely-revolving pulleys F and f^6, independently-mounted cam and cop carrying spindles c^2 and H respectively, a pulley secured to said cop-spindle, an endless power-transmitting belt *x* in engagement with the said pulleys, intervening mechanism actuated by the said pulley f^6 for revolving the cop-spindle, and a reciprocating yarn-guide arranged with respect to the spindle H and having its movements controlled by the cam-spindle, substantially as described.

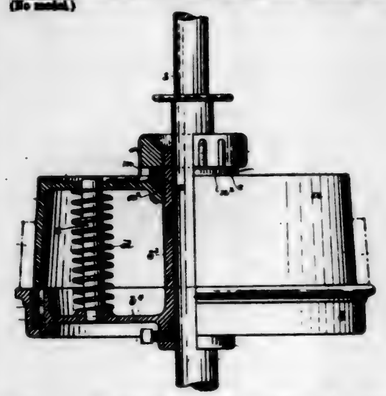
8. In a winding-machine, the combination with the revolvable vertically-arranged cam-carrying shaft or spindle c^2 and a pulley f^6, through which power is transmitted for actuating said spindle, of the revolvable vertically-mounted and laterally-movable cop-carrying spindle H, a pulley secured thereto for actuating the spindle, an adjustably-mounted idler-pulley *k* adapted to revolve in a horizontal plane below said cop-spindle pulley, an initial driven pulley adapted to be actuated by any suitable driving means, and an endless open belt *x* in continuous engagement with said four pulleys, whereby when in use the cam and cop spindles are rotated at different rates of speed, substantially as described.

9. In a winding-machine, the combination with the suitably-mounted revolvable laterally-movable cop-spindle and the vertically-reciprocating yarn-guide *d*, of the yarn-tension device N provided with a pair of yielding friction-disks *n'* between which the yarn or thread passes, and a cam or wedge moving in unison with said cop-spindle, whereby as the cop increases in diameter the tension-cam gradually reduces the pressure upon the yarn between the friction-disks, substantially as described.

10. In a winding-machine, the combination of a cop-spindle and a slidable plate or carriage having said spindle revolubly mounted therein, means for driving said spindle, a reciprocating yarn-guide, a yielding tension device for the yarn having a member thereof connected with said movable carriage arranged to automatically reduce the tension upon the yarn as the cop increases in diameter, and means connected with the carriage and with said spindle-driving mechanism, whereby the speed of the spindle is automatically and gradually changed as the cop, which is being built thereon, increases in diameter, substantially as described.

11. In a winding-machine, the combination of a vertically-reciprocating yarn-guide, a freely-turning guide-roll mounted contiguous to the delivery side of said yarn-guide, and a laterally-movable and revolvable cop-spindle having the surface of the cop, while being produced thereon, in substantially continuous engagement with the said guide-roll, substantially as described.

707,685. ADJUSTABLE OR SEPARABLE PULLEY. RISDON C. FAY, Pawtucket, R. I., assignor to the Easton & Burnham Machine Company, Pawtucket, R. I. Filed Mar. 25, 1902. Serial No. 99,002. (No model.)



Claim.—1. The adjustable or separable pulley herein described, the same comprising a main or head member provided with a guide-flange having a comparatively deep annular peripheral recess therein, an endwise-movable rim member having a beveled face arranged to enter said recess, said two members when in action always revolving in unison, and means for changing the relation or relative position of the head and rim members, thereby varying the speed of the belt or pulley, as the case may be, substantially as hereinbefore described.

2. In a pulley of the class described, a head member adapted to be secured to a shaft, having an outer or peripheral guide-flange for the adjacent edge of the belt and a comparatively deep annular recess or groove contiguous to said flange, in combination with a rim member having a beveled face adapted to enter said recess, means uniting or connecting said head and rim members whereby when in action they revolve in unison, and adjusting mechanism for changing the position of the rim endwise or longitudinally with respect to the flange member, substantially as hereinbefore described and for the purpose set forth.

3. In a pulley of the class described, a head member provided with a peripheral guide-flange for the belt and also having a screw-threaded hub and guide-pins, in combination with a rim member having a beveled face slidably mounted on said hub and pins, springs interposed between the head and rim members, and a nut fitting said screw-threaded portion of the hub, substantially as described and for the purpose set forth.

4. An adjustable or separable pulley provided with longitudinally-separated spring-pressed head and rim members arranged when in use to always revolve in unison, said rim having a beveled face, a lock-nut fitted to the hub of said head member, whereby the relation of the rim to the head member may be adjusted longitudinally of the shaft and maintained in position, and having that portion of the said rim adapted to enter a comparatively deep annular recess formed in said head member, thereby changing the working diameter of the pulley, substantially as described.

707,686. COKE-DRAWER. DAVID FERGUSON, Pittsburg, Pa., assignor of one-half to Oliver G. Ferguson. Filed Apr. 1, 1901. Serial No. 53,773. (No model.)

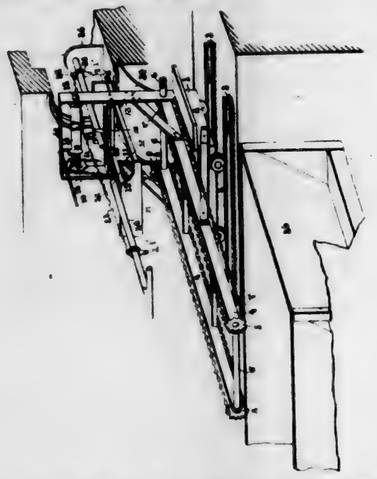
Claim.—1. In a coke-drawer, a frame, a drum mounted therein, a reach-rod, a flexible device operatively connecting the drum and the rod, a conveyer, disconnectible driving connections between the conveyer and the drum, and means secured to the rod to which power may be applied for driving the rod and the drum when the rod is entering the coke-oven.

2. In a coke-drawer, a frame, a drum mounted therein, a support having a slot parallel to the axis of the drum, a swiveled forked bearing adjustable in the slot, an axially-rotatable reach-rod in the forked bearing, a flexible device on the drum and secured to the reach-rod, and means on the latter to which power may be applied for driving the rod and the drum when the rod is entering the coke-oven.

3. In a coke-drawer, a frame, a winding-drum therein, a support beneath the drum, a swiveled bearing adjustable on the support independently and longitudinally of the axis of the drum, a reach-rod seated in the bearing, a flexible device operatively connecting the drum and the rod, and means for operating the drum.

4. In a coke-drawer, a frame, a winding-drum, and a support independently mounted therein, a swiveled forked bearing adjustable along

the support independently and longitudinally of the axis of the drum, an axially-rotatable reach-rod seated in the forked bearing, a flexible device wound on the drum and having its ends fastened to the reach-rod, and means for moving the rod longitudinally.



5. In a coke-drawer, a frame, a drum and a slotted support independently mounted therein, a swiveled forked bearing adjustable in the slot of the support independently and longitudinally of the axis of the drum, an axially-rotatable reach-rod seated in the forked bearing, a flexible device wound on the drum, and having its ends fastened to the rod, and means for longitudinally moving the rod.

6. In a coke-drawer, a reach-rod, a fulcrum-support therefor, and a slidable rod-rest below the same.

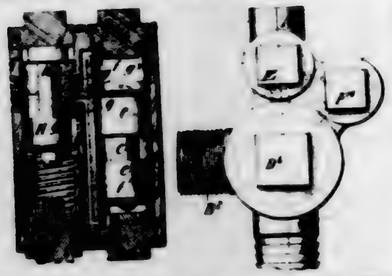
7. In a coke-drawer, a reach-rod, a fulcrum-support therefor, a slidable rod-rest below the rod, and means on the rod for sliding the rest.

8. In a coke-drawer, a reach-rod, a support therefor, a slidable rod-rest and projections on the rod for sliding the rest.

9. In a coke-drawer, the combination of a rotatable reach-rod, said rod having a downwardly-projecting rod, a support for the rod, a movable rod-rest below said rod, a drum, a chain secured to said drum and to the forward end of said reach-rod, and means for withdrawing said rod.

10. In a coke-drawer, a power-driven endless conveyor, a winding-drum, a driving device loose thereon and geared to the conveyor, a collar slidably held thereon, means for interlocking and disconnecting said device and collar, a reach-rod, a flexible device secured to said rod and wound on the drum, a blade on the rod, and a chain leading to the conveyor.

707,687. AUTOMATIC GOVERNOR FOR FLUID-COMPRESSORS. JOSEPH P. PILLINGER, Bellevue, Mich., assignor of nine-tenths to Richard B. Hicks and Eugene L. Markey, Bellevue, Mich. Filed Oct. 12, 1901. Serial No. 78,469. (No model.)



Claim.—1. The combination of the pump-chamber, the relief-port communicating therewith, and with the atmosphere, a relief-valve chamber into which said port opens, and a relief-valve in said chamber, adapted to close said relief-port in one position and open same in another position; with a governor-valve chamber, a passage for admitting air which has been compressed by the pump into one end of said governor-valve chamber, a governor-valve operated one way by air-pressure, a spring for forcing said governor-valve in the other direction, adjoining pairs of ports leading respectively from the governor-valve chamber to the atmosphere, and to opposite ends of the relief-valve chamber, said governor-valve being adapted to establish communication through said ports between one end of the relief-valve chamber and the governor-valve chamber, and between the other end of the relief-valve chamber and the atmosphere, or vice versa, all substantially as and for the purpose described.

2. The combination of the pump, the relief-valve chamber, the valve therein, the adjoining governor-valve chamber, the piston therein, a spring for moving said piston in one direction, and means for admitting air which has been compressed by the pump into said chamber to move the piston against the spring, air-ports opening near their adjoining ends into the air-space of the governor-valve chamber, and at their other ends into opposite ends of the relief-valve chamber, and exhaust or venting ports adjacent to the air-ports and respectively opening at one end into the air-space of the governor-valve chamber near the mouths of the air-ports and at their other ends into the atmosphere; with a governor-valve in the governor-valve chamber, operated by the piston therein, having a central passage communicating with the air-space of the governor-valve chamber and adapted to register with either of the said air-ports, said governor-valve also having two pockets respectively adapted to alternately establish communication between the respective air-ports and the related venting-ports, substantially as and for the purpose set forth.

3. The combination of the pump, the relief-valve chamber communicating therewith, the double-ended relief-valve in said chamber, and an outlet-port from said chamber communicating with the atmosphere; with the governor-valve chamber beside the relief-valve chamber, a passage for admitting air which has been compressed by the pump into said governor-valve chamber, air-ports leading from the governor-valve chamber to the opposite ends of the relief-valve chamber, and two vent-ports adjacent to the air-ports leading from said governor-valve chamber to the atmosphere; with the slide-valve having passage g^3, communicating with the air-space in the governor-chamber, and pockets g, g' respectively adapted to establish communication between adjacent air and vent ports, a piston carrying said slide-valve, and an adjustable spring for holding the piston against the air-pressure, substantially as and for the purpose described.

4. The combination of an air-pump, an air-storing reservoir communicating therewith, and the main air inlet and outlet valves; with a relief-valve chamber adjacent to said valves, ports connecting the same with the pump and with the atmosphere, a relief-valve in said chamber adapted to normally close said ports, a governor-valve chamber communicating at one end with the reservoir; a piston in said governor-valve chamber adapted to be depressed by the pressure of the air which has been compressed by the pump, a spring for raising said piston opposite ports leading from the air-space of the governor-valve chamber to the opposite ends of the relief-valve chamber above and below the relief-valve; vent-ports leading from the governor-valve chamber to the atmosphere, a governor-valve in said governor-valve chamber actuated by the piston, and adapted to establish communication between either relief-valve port and the governor-valve chamber, and the other relief-valve port and the atmosphere so as to cause the compressed air to actuate the relief-valve and render the pump effective or ineffective in operation, substantially as described.

5. The combination of the working cylinder or pump-cylinder, its inlet and outlet valves, a relief-port communicating with said cylinder intermediate the valves, a relief-valve, a governor-valve chamber beside the relief-valve casing, a piston therein, operated one way by the air which has been compressed by the pump; a spring for forcing said piston in the opposite direction; opposite air-ports leading from the air-chamber in the governor-valve casing to the relief-valve casing and opening thereinto on opposite sides of the relief-valve, adjacent vent-ports in the walls of the governor-valve chamber, and a governor-valve operated by the piston controlling said opposite air-ports and adjacent vent-ports, and means for venting one end of the governor-valve casing when air is admitted to the opposite end thereof.

6. The combination of the pump-cylinder, the pump-valve chamber, the adjacent valves therein, the relief-valve chamber, a relief-port leading from the pump-valve chamber between the valve therein to the atmosphere, a relief-valve adapted to close said relief-port in one position and open it in another position; a governor-valve chamber, air-ports leading from the governor-valve chamber to the relief-valve chamber and opening therein, at opposite sides of the relief-valve, and vent-ports leading from the governor-valve chamber to the atmosphere, a slide-valve in the governor-valve chamber for controlling said air and vent ports, a piston connected to and actuating said slide-valve, a passage connecting the pump-valve chamber with the governor-valve chamber to admit air which has been compressed by the pump into the governor-valve chamber above the piston, and a spring for holding the piston against the air-pressure, substantially as described.

7. The combination of the pump-cylinder, the crank-case, the relief-valve chamber, a port leading from said chamber to the pump, and a second port leading from said relief-valve chamber to the crank-case; with a relief-valve in said chamber, and means controlled by the air-pressure whereby said relief-valve is opened when the pressure rises above the desired degree, substantially as described.

8. The combination of the pump, the pump-valves at one side thereof, the compressed-air reservoir, and the crank-case, the relief-port for the pump; a relief-valve chamber communicating therewith, a port or passage connecting said relief-valve chamber with the crank-case, a relief-valve in said chamber, a governor-valve chamber, ports connecting the governor-valve chamber with the relief-valve chamber, and ports leading from the governor-valve chamber to the atmosphere; a valve in the governor-valve chamber controlling all ports thereof, a spring for holding the governor-valve against the air-pressure, and an air-channel leading from the reservoir to the governor-valve chamber above the valve therein, all substantially as and for the purpose described.

9. The combination of the pump-cylinder, the crank-case, the relief-valve chamber, a port leading from said chamber to the pump, another port leading through said cylinder-wall to the crank-case, a relief-valve in said chamber adapted to close said ports in one position and open them in another position; a governor-valve chamber beside the relief-valve chamber, ports leading from the governor-valve chamber to the relief-valve chamber and opening therein at opposite sides of the relief-valve, a slide-valve in the governor-valve chamber for controlling said ports, a piston connected to and actuating said slide-valve, a passage for admitting compressed air into the governor-valve chamber above the piston, and a spring for holding the piston against the air-pressure, substantially as and for the purpose described.
